internally and to cause obstructions, it should be planted in cuttings in December; it grows quickly; its wood might be used for basket hoops. The tree affords a grateful shade, and though continually stripped of its leaves, which are extensively used for manuring indigo fields in Cuddapah, it quickly replaces them and that abundantly.—*Dr. Cleghorn.* Poinciana Gilliesii. Most of these plants are Natives of India; one well known as the Goolmohur flowers, grown from seed. P. Gilliesii is from Mexico.—*Riddell.*

(6452) POINCIANA PULCHERRIMA.

Krishna choora, Beng. | Gul-i-turah, Hind.

Is said to be much used in medicine in upper India, but for what purpose, is not stated. Ainslie notices the plant under the name of *Kurrish-churria.* A decoction of the leaves and flowers is given as a febrifuge in Tortola; the leaves are purgative, and when bruised smell like sabine; in infusion they are considered powerfully *emmenagogue.* These properties demand careful investigation.—*O'Shaughnessy, p.* 317. This gaudy ever-flowering shrub is planted in Barbadoes for hedges; it is much cultivated by the Burmese, and the variety with yellow blossoms is occasionally seen in their gardens. It is sometimes called peacock's pride, and Spanish carnation.—*Mason.* It is commonly cultivated at Ajmeer; it is a splendid shrub during the rains and very hardy.—*Genl. Med. Top. p.* 192. This beautiful plant, grows to the height of five or six feet, the leaves during the rains are green, and afterwards become of a bright scarlet having a most showy appearance, easily propagated by cuttings, both leaves and bark contain a milky juice which when dried and boiled possesses some of the properties of gutta percha.—*Riddell.* This plant has been recently introduced into the gardens in Maulmain; and its large vermillion-colored floral leaves render it, when in flower, a very ornamental plant.—*Mason.*

(6453) POINCIANA REGIA. A large tree with showy coloured flowers. Introduced from Madagascar, and still confined to gardens. The wood seems good. Hort. Garden 21.—*M.E.J.R.* This gorgeous shrub which has been introduced from Madagascar into India, bears a most magnificent and graceful flower; and as it flourishes well in the Tenasserim Provinces, if it were generally planted in gardens, it would add much to their beauty.—*Mason.*

(6454) POIVREA COCCINEA. *Syn.* Combretum purpureum. This at present is the popular favorite amongst climbing plants in Madras; requires a trellis not too high, the sooner it gets a procumbent position the more luxuriant it will grow and flower, best for pot cultivation, easily propagated by cuttings of the young wood in sand under glass. Native of Madagascar.—*Jaffrey.*

(6455) POIVREA GRANDIFLORA. *Syn.* Combretum grandiflorum. Similar to the above in habit but having far superior flowers. Native of S. Leone.—*Jaffrey.*

(6556) POIVREA ROXBURGHII. Among the fibrous barks sent from Assam to the Exhibition of 1851, was one that was named Roxburghia in the Catalogues. This is no doubt a mistake for some plant called after Dr. Roxburgh, probably *Poivrea Roxburghii,* one of the *Combretaceæ,* of which several are remarkable for tough wood as well as bark.—*Royle Fib. Pl. p.* 301.

(6457) POLANISIA (from πολ many, and ἄνισος unequal; stamens numerous and unequal), a genus of Plants belonging to the natural order *Capparideæ.* It has 4 spreading sepals; 4 petals; a small torus; silique sessile within the calyx, or hardly stipitate, terminated by a distinct style.—*Eng. Cyc.* Dr. Wight gives, Polanisir Burtporensis, 1072; chelidonii, 310; and icosandra, 7. The genera Cleome and Polanisia, embrace several species of supposed medicinal virtues. Ainslie describes five species. The *Cleome felina* (cat's cleome, *Eng.* Swarnakshira, *Sans.*) is used as an astringent in northern India and Ceylon. The *C. pentaphylla,* (*Vern.* Hurhuriya, *Beng.* Carnila, *Hind.* Hoolhool, *Duck.* Caravela and Varsar, *Sans.*) affords small, black, rather aromatic seeds, used by the natives in decoction as a stimulant drink in low fevers, and in some forms of convultion. The expressed juice too is considered stimulant, and sudorific. The *C. viscosa,* or viscid Cleome (*Vern.* Hoorhooria, *Hind.* Savana barbara *Sans.*) is also celebrated for its seeds, the *Chorie-ajooain,* of the bazars. These are believed to be vermifuge and stumulant, and are given to the extent of a tea spoonful twice daily (Ainslie.) The C. *dodecandria* and *icosandria* of Ainslie are identical with this plant, and are described by Lindley as *Polanisia icosandra.* In Cochin China the whole plant bruised is used like sinapisms for counter-irritation, and blistering. This fact deserves attentive experimental investigation.—*O'Shaughnessy, p.* 206.

(6458) POLANISIA ICOSANDRA, has a stem covered with viscid glandular hairs, 3-5 foliolate leaves, the leaflets obovate, cuneate, or oblong pubescent, scarcely longer than the petiole; the stamens are about 10 in number; the silique terete striated, rough with glandular horns, sessile and acuminated. It is a native of the East Indies, and is used in Cochin China as a counter-irritant in the same way as sinapisms in Europe, and as a vesicant. The root is used as a vermifuge in the United States of America.—*Eng. Cyc.* The leaves of this very common weed when bruised, are said to act as a sinapism.—*Mason.*

(6459) POLISHING SLATE, *Polier Schiefer*, a Mineral, occurring massive, with a slaty texture. Its colour is white, yellowish-white, or yellow. Brittle. Opaque. Specific gravity 0·59. It is found near Bilin in Bohemia, at Zwickau in Saxony, and Auvergne, and is supposed to be a volcanic product. Its analysis by Bucholz gives,

Silica	83·5
Alumina	4·0
Lime	8·5
Oxide of Iron	1·6
Water	9·0
	——106 6

(6461) POLYANTHUS, a garden variety of the Oxlip Primrose, with brown flowers, is one of those plants which have, from time immemorial, been favourites in gardens. It was probably obtained by accident, and is now propagated either by seeds or division of its root.—*Eng. Cyc.*

(6462) POLYANTHUS TUBEROSA, grows at Lahore and on the hills. The natives say its seeds are the white Todree of the oriental bazars which, as also the other Todrees, Europeans supposed to be from Malacca. Whatever they may be they are effective medicine.—*Dr. Honigberger, p.* 329. This, "the tuberose with her silvery light," a plant of the lily tribe, which has been introduced into India from Mexico or South America, is cultivated very extensively by the Burmans and in many English gardens. The flower has a delightful fragrance, and throws out its odours strongest at evening.—*Mason.*

(6463) POLYGALA SENEGA, SNAKE ROOT. *The roots.* Several species of Polygala are medicinally employed in Germany, South America, and Java. In Nipal and the Himalayas, the P. crotalarioides is used as a snake antidote. Of this species the stem is branched from the base, suffruticose, decumbent, downy; leaves obovate, wedge-shaped at the base, stalked; racemes 8—10 flowered, wings roundish, obovate, as long as the orbicular, ciliated capsule. In the Moluccas the *Soulamea amara* (Rex amarois) is stated to be employed with great advantage in cholera, and in ague. All parts, especially the roots and fruit, are excessively bitter.—*O'Shaughnessy, pages* 209-12.

(6464) POLYGALA SPECIOSA.—All the species of this genus are very handsome, showy flowers, they are natives of the Cape, some parts of Europe and America; their colours are chiefly pink, scarlet, red or white, they are readily grown from seed, and should be raised in a light soil.—*Riddell.*

(6465) POLYGONACEÆ, *Buckwheats*, a naturalorder of Apetalous Plants, with triangular fruit and usually with stipules united into a tube or ocrea, through which the stem passes. Their fruit is composed of three aspermous carpellary leaves joined by their edges, and surrounding a single erect ovule deriving its origin from a central placenta; and it proves the truth of the modern theory, that in many cases the ovules derive their origin immediately from the centre of vegetation, or the growing point, and not from the margin of carpellary leaves. The order consists of herbaceous plants more frequently than of shrubs, and a large part of them are mere weeds; as, for example, our docks, and wild polygonums; some however are handsome flowers,, as the *P. orientale*, or Garden Persicaria, and *P. amplexicaule*; others are valuable for cooking, as the rhubarb, whose roots also furnish the important tonic and purgative drug of that name; and in some a great quantity of astringent matter is found, as in the *Coccoloba uvifera*, or Seaside Grape of Jamaica, from which a kind of Kino has been prepared. [COCCOLOBA]. A species of Indian *Polygonum*, *P. tinctorium*, has recently been introduced into cultivation in Belgium as a substitute for indigo. The flour of the seeds of *P. Tartaricum*, *P. Fagopyrum*, and others, is made into a bad kind of bread in Lombardy and other countries. The genus *Rheum* also belongs to this order.

(6466) POLYGONUM (the Greek πολύγονον, 'much productive'), a genus of Plants belonging to the natural order *Polygonaceæ*. It has a 5-parted perianth, from five to eight stamens, and from two to three styles; a 1-seeded trigonous or compressed nut, lateral incurved embryo, the cotyledons not contorted. This is a very extensive genus, containing the Knotgrasses, Bistorts, Persicarias, and Buckwheats of English waysides, fields, and gardens. They grow in almost any soil, some being aquatic, and others flourishing in sandy sterile tracts.—*Eng. Cyc.* Roxburgh in his second volume, p. 285 et seq., (Octandria trigynia) names 15 species of Polygonum, but no information as to their properties. His *P. lanatum*, common round Calcutta, is called *Sweet panee merich*, or white water pepper; *P pilosum; burra panee merich*, or great water pepper, is also common near Calcutta, and flowers at the beginning of the wet season. The name denotes its analogy in properties to the P. Hyderopiper of Europe, which gives a yellow colour to wool; *P. flaccidum* is also called *Panee merich* in Calcutta.—*O'Shaughnessy, page* 523.

In China, two species of Polygonum are cultivated for the blue dye furnished by the leaves, which is extracted like indigo by maceration.—*Williams' Middle Kingdom, page* 282. In Icones. Dr. Wight gives Polygonum ambiguum 1797; *aviculare*, 1808; barbatum, 1798; Chinense, 1806; Donii, 1801; glabrum, 1799; horridum, 1803; Indicum, 1808; molle, 1807; Nepalense 1804; pedunculare, 1802; strictum, 1800; Wallichii, 1805.

(6467) POLYGONUM AMPHIBIUM. The Root-like stems of this polygonum, resemble sarsaparilla, as a substitute for which it has been used with alleged success.—*O'Shaughnessy, page* 523. Vegetates in Cashmere, and is considered as a veterinary medicine; whence its name, gurec (horse).—*Honigberger, p.* 330.

(6468) POLYGONUM AVICULARE, KNOT GRASS.

Nisomali, SANS. Machooti, HIND.

Considered medicinal in Behar. Fruit said to be emetic and cathartic.—*O'Shaughnessy, page* 522. Polygonum Aviculare has from one to three flowers together, axillary lanceolate leaves, or elliptical. Plane stalked lanceolate acute ocreæ, with few distant simple nerves at length by growth becoming torn, a triquetrous nut with raised points shorter than the perianth. Its numerous seeds supply abundant food for small birds; they are said to be emetic and cathartic. Thunberg says that in Japan a blue dye is prepared from this plant.—*Eng. Cyc.* Polygonum aviculare—grows at Cashmere, and is there officinal. Its fruit is said to be emetic and cathartic (Beng. Disp.)—*Honigberger, page* 330.

(6469) POLYGONUM BARBATUM, China and East Indies.

Aatalari, TAM. | Kuuda mallier, TEL.

Considered diuretic at the Cape of Good Hope and given in infusion by the native doctors in India in cases of colic.—*O'Sh. p.* 522.

(6470) POLYGONUM CYMOSUM. Wall. A wild buckwheat is abundant, at Choongtam in Sikkim which formed an excellent spinach: it is called "Pullopbi;" a name I shall hereafter have occasion to mention with gratitude. This is a common Himalayan plant, and is also found in the Khasia mountains.—*Hooker Him. Jour. Val.* II. *page* 31.

(6471) POLYGONUM LINIFOLIUM as also Poligonum aviculare and affinis species; grows about Lahore, where it is well known, but little used.—*By Dr. Honigberger, p.* 330.

(6472) POLYGONUM MACROPHYLLUM. grows among the Cashmerean mountains, where its roots are officinal.—*Dr. Honigberger, p.* 330.

(6473) POLYGONUM MOLLE, grows on the Cashmerean mountains and its roots are officinal at Cashmere.—*Dr. Honigberger, p.* 330.

(6474) POLYGONUM PERSICARIA. This is a very extensive genus of plants; the dwarf persicaria, a garden plant, is of easy culture, also the red and white: the P. Hydropiper, a water plant, has beautiful pink flowers.—*Riddell.*

(6475) POLYGONUM TINCTORIUM, *chinense*, and *barbatum*, yield a blue dye like indigo, in China and Japan.—*O'Shaughnessy, page* 523. See DYES.

(6476) POLYNEMUS, a genus of Fishes, placed by Cuvier in his third division of the *Percidæ*, the species of which are distinguished by the ventral fins being inserted farther back than the pectorals. These fishes are further distinguished by having several long filaments beneath the pectoral fin; these are, in fact, free rays of that fin; their teeth are minute and dense as the pile on velvet, or recurved like the teeth in a carding-machine; they are found on both jaws, as well as on the vomer and palate. The general form of the body of the *Polynemi* somewhat resembles that of the perch; the muzzle projects over the mouth; the eyes are rather large and placed very forward; the dorsal fins are short and widely separated, and the caudal fin is large, and more or less forked. The scales extend on the fins, as in many of the *Sciænidæ*, which these fishes appear to approach in some other characters. Considerable interest is attached to the *Polynemi* on account of their yielding isinglass. This fact was first made known by Dr. Cantor, who found that several species of *Polynemus* might be used for obtaining isinglass. "The species best known," says Dr. Cantor, in a communication to the Zoological Society, "is the *Polynemus Risua* of Hamilton (*P. longifilis*, Cuvier; the Tupsee, or Mango fish, of the Anglo-Indians): this inhabits the Bay of Bengal and the æstuaries of the Ganges, but enters the mouths of the rivers even higher up than Calcutta during the breeding season (April and May), when the fish is considered in its highest perfection, and is generally sought as a great delicacy. This species is the smallest, for its length seldom exceeds eight or nine inches, and one inch and a half or two inches in depth." It is remarkable for the great length of filaments, or free rays, of the pectoral fins, these being about twice the length of the body, and seven in number on each side. *P. aureus* and *P. Topsui* of Hamilton, Dr. Cantor states, are closely allied to this species. "*Polynemus Sele*, Hamilton (*P. plebeius*, Broussonnais; *P. lineatus*, Lacepède), is the Suleah Fish first mentioned in Pardoe's 'Oriental Herald,' as yielding isinglass. This species, as well as another closely allied to *P. quadrifilis*, Cuvier, which was dissected, figured, and described, under the name of *P. Saltish* (Saccolih), appears to be equally plentiful, in

shoals, all the year round, in the estuaries of the Ganges, and is appreciated by Europeans for its excellent flavour: both species attain a size from three to four feet in length, and eight to ten inches in depth." (Cantor.) Besides the species found on the coast of the mainland, two other species of *Polynemus*, *P. heptanemus* and *P. heptadactylus*, have been discovered off the coast of Java. On the coast of Africa and in the West Indies, certain species of the present genus are found. One of the African species is confounded by Cuvier with the Indian *P. longifilis*, and the mistake has been rectified by Mr. Bennett. It appears that this species (which is in all probability the *Pentanemus* of Artedion, which Linnæus established his *P. quinquarius*) differs from the Mango Fish of India in the number of free rays to the pectoral fins, the latter having seven rays, and the African species only five. Messrs. Cuvier and Valenciennes, not having found any species of *Polynemus* with so few as five free rays, and those longer than the body, imagine that the *P. quinquarius* was founded on a mutilated specimen. Several individuals however having this character being discovered by Captain Belcher, R. N. during his survey of a part of the Atlantic coast of North Africa, Mr. Bennett proposed to name the species after Artedi. The second African species belongs to that section in which the free rays of the pectoral fins are short, and has received the name of *Polynemus quadrifilis*. In the American *Polynemus* (*P. Americanus*) there are seven free rays to the pectoral fin, and these scarcely reach the tip of the ventral fins: it is about one foot in length, of a silvery colour; the pectoral fins are almost black, and the other fins are spotted with black.—*Eng. Cyc.*

(6477) POLYNEMUS INDICUS. Robal Fish.

Cala meen. Tam.

(6478) POLYODONTA ('many-toothed' tribe), a name applied by Lamarck and M. De Blainville to the *Arcacea* [Arcadæ] of the former, the Ark-Shells, &c., of collectors, comprehends the forms collected by Linnæus, in his 'Systema Naturæ,' under the genus *Arca*, and those designated by more modern zoologists as the genera *Arca*, *Cucullæa*, *Pectunculus*, and *Nucula*. "Cardinal teeth small, numerous, entering, and disposed in each valve in either a straight, a curved, or a broken line."

Arca (Linn.).—Animal more or less thick, generally rather elongated: mantle prolonging itself slightly backwards, and with a row of tentacular filaments on its borders; labial appendages very small and slender; foot pedunculated, compressed, and slit throughout its length. Shell navicular, rather thick, equivalve, inequilated, more or less oblique; umbones distant and often a little recurved forwards; hinge linear; straight furnished throughout its length with a numerous row of small teeth or transverse laminæ, which are equal and intrant; ligment entirely external M. Rang, who gives the above as the characters of *Arca*, remarks that the species sometimes adhere by their foot, and more frequently by means of a byssus.

(6479) *A. tortuosa* (Genus *Trisis*, Oken). Shell twisted, parallelopiped, striated; valves obliquely carinated: umbones small, recurved. It inhabits the Indian Ocean.

(6480) *A. antiquata*. Shell transverse, obliquently cordate, ventricose, many ribbed; the ribs transversely striated and blunt: the posterior ribs bifid. Colour white.

The *Arcæ* have hitherto been found on bottoms of sandy mud and dirt, at depths varying from the surface to seventeen fathoms. Some of the species are moored to stones, corals, &c.—*Eng. Cyc.*

(6481) POLYPIFERA, POLYPIARIA, or POLYPI, an order of Radiate Animals, thus characterised by M Milne-Edwards:—Animals organised for sedentary mode of life, having no locomotive organs, and being provided with a circle of retractile tentaculæ around the mouth, and a central gastric cavity, not communicating with an anus, and containing the reproductive organs when these exist, in general fissiparous, or multiplying by buds as well as by ovules.—*Eng. Cyc.*

(6482) POLYPODIACEÆ are one of the chief divisions of the natural order of Ferns. [Filices.] They constitute the highest form of Acrogenous or Cryptogamic vegetation, and are regarded as approaching more nearly to Cycadaceous Gymnosperms than to any other part of the vegetable kingdom now in existence. They are usually herbaceous plants, with a permanent stem, which remains buried and rooting beneath the soil, or creeps over the stems of trees, or forms a scarcely moveable point of growth, round which new leaves are annually produced in a circle; or it rises into the air in the form of a simple stem, bearing a tuft of leaves at its apex, and sometimes attaining the height of 50 or 60 feet. [Acrogens.] The stems seem always to produce roots in great quantities from their surface, even when elevated in air; such roots are more especially met with near and under the ground, where they form a stratum of some thickness, acting both as feeding-organs and as an external protection; on all Tree-Ferns they appear upon the stem at least in the form of tubercles; and in *Cibotium Billardieri* they cover over the whole surface from the top to the bottom with a dense layer several inches deep. The surface of tree-fern stems may be taken to represent that of the order in general. It is always marked with scars of considerable size, having either a lozenge form or that of an

irregular oval, and bearing within their area evident traces of the fracture of woody plates which passed from the stem into the leaves. These scars lengthen as the stem increases in age, till the lozenge or oval form is entirely destroyed; the scars then become separated to considerable distances, and extended into long and often irregular and indefinite spaces separated by deep furrows. Hence it happens that the appearance of the upper and lower end of the same tree-fern stem is so dissimilar, that they would not be supposed to belong to even the same species. Below the scars, or interposed among them, are found openings down into the interior of the stem filled with pulverulent matter, and of unknown use. They appear to be of the same nature as the apertures into the superficial cells of *Sphagnum*, or more especially as the perforations in the rhizoma of *Nymphæa*. Although tree-ferns are unknown in any countries except those having either a damp tropical climate, or at least an equable mild temperature and humid atmosphere, yet the common ferns of Britain, whose stems, vulgarly called roots, are formed under ground, exhibit the same kind of organisation as that just described, only in a less conspicuous manner. It does not therefore follow that the remains of tree-ferns found in this country in a fossil state prove Great Britain to have had formerly a tropical climate, especially as the number of such remains hitherto met with has been extremely small; the utmost value that can be assigned to their evidence is that of probability. In those tropical lands where the tree-fern acquires its full size, as for example Brazil, the Philippines, Pitcairn's Islands, &c., it becomes one of most majestic and graceful objects, having an enormous plume of the most delicate and verdant foliage at the extremity of a lofty flexible stem, which sways beneath the gentlest breeze.—*Eng. Cyc.*

(6483) POLYPODIUM, a genus of Ferns, type of the natural order *Polypodiaceæ*. The species of this genus are known by the thecæ being in clusters on the back of the frond, and by their opening transversely; the ring is usually vertical and incomplete. This is the case with *Allosurus* and *Noodsia*. *Polypodium* is distinguished by the sori being circular and naked, and the margin of the frond is flat, not reflexed. Several species are found in Great Britain. —*Eng. Cyc.*

(6484) POLYPODIUM. Reed Fern. There is a large terrestrial fern with hollow stems like a reed, which are often used by the natives of Tenasserim instead of quills for pens.—*Mason.* In Calcutta, the Hindoos boil the young tops of a *Polypodium* with their shrimp curries.—*Hooker.*

(6485) POLYPODIUM GIGANTEUM. A tree fern is very rare but is occasionally seen in the southern Provinces, resembling a small palm. Griffith found the same species in Assam. The natives have but one name for both the cycas and tree fern.—*Mason.*

(6486) POLYPODIUM PERTUSUM. Pitted Polypod. In Tenasserim, this fern is often found in company with the preceding species; and may be easily recognized by its creeping habit, and by the margins of the upper parts of its fronds being rolled together when in fructification.—*Mason.*

(6487) POLYPODIUM PROLIFERUM, is the only species of fern that the Soane valley presents at one season of the year. The rocks are then elegantly fringed with it.—*Hooker, Him. Jour Vol.* 1, *p.* 50.

(6488) POLYPODIUM QUERCIFOLIUM, Oak-leaved Polypod. In some parts of the forests of Tenasserim the trunks of almost every tenth tree have a great abundance of a large species of polypod growing upon them. The barren fronds are cordate, and stemless; but the fertile ones stand on long slightly winged stems, and are gashed like the leaves of an English oak. —*Mason.*

(6489) POLYPODUM SEKOUR, grows on the lower range of the hills, near Jowalla mukkee. Its dried roots are white, resembling slices of pears.—*Dr. Honigberger, p.* 330.

(6490) POLYPODUM TAXIFOLIUM. Lin.

Wellipanna-Kelengu, Hort. Mal.	Kadehou Maa, Sans.

Rheed says that the leaves of this plant, reduced to powder, and taken with honey, are powerful emmenagogues, and bring on abortions. He therefore adds, Mulieres, ergo, cavete vobis.—*Vide Hort. Mal. par.* 12. *page* 25.—*Ains. Mat. Med. p.* 134.

(6491) POLYPODIUM VULGARE. Bisfay. Common Fern is officinal at Lahore, whither it is brought from the hills. The Hakims use it to purge away the black bile in melancholy also in flatulent colic. They think it injurious to the liver.—*Dr. Honigberger, p.* 330. The root is brought to Ajmere from Arabia, via Bombay: considered heating and given in flatulence, and indigestion; not considered poisonous in any quantity: one seer costs four rupees.—*Irvine.*

(6492) POMACEÆ, Juss. Apple Tribe. The Pomaceæ form a tribe of Rosaceæ in the system of De Candolle, but by many botanists they are separated into a distinct family. They may be distinguished from other Rosaceæ by their leaves being usually simple, the tube of the calyx adherent to the ovary; and thus, including the carpels, a fleshy fruit is eventually formed, which is crowned by the limb of the calyx, and is well known in the Apple, Pear, Quince, &c., whence it is called a Pome. This may be from 2—5 celled, each cell formed of cartilaginous or

bony membrane, and containing 2 or more erect ovules.—They mostly inhabit the North temperate Zone and the great mountainous range of India. They are chiefly remarkable for their edible fruit when cultivated, abounding in saccharine matter with a pleasant acidity. In a wild state, they are austere or astringent and acid. By distillation of the seeds of some of the Pomaceæ a very little Hydrocyanic acid is obtained.—*Royle.* A wild apple, which bears a small austere fruit like the Siberian crab was found in the Bhoottea country in East Nepaul.—*Hooker, Him. Jour. Vol.* 1, *p.* 205.

(6493) POMEGRANATE.

Rana Rooman. Arab.	Dalema, Mal.
Delunghidie, Cyng.	Anaar, Pers.
Grenades, Fr.	Roomaas, Port.
Granatapfel, Ger.	Dadima, Sans.
Anaar Darim, Guz. &. Hind.	Granadas, Sp.
Granati, It.	Magilum palam, Tam.
Gangsalan, Jav.	Dadima Pundoo, Tel.
	Nar, Turk.

The fruit of a tree (*Punica Granatum*), common in the warmer parts of the temperate zone. Pomegranates when ripe, are about the size of an orange, are covered with a hard, light brown rind, and contain a reddish, seedy, juicy pulp. The rind of the pomegranate has of late years formed an article of export from Bombay to England, where it is used in medicine.—*Faulkner.* In China, dried pomegranates are said to be used for dyeing yellow; the rind is also a tanning substance. In the "Comptes Rendus," xxxv., p. 558, there is an account by M. J. Persoz, of a green coloring matter from China, of great stability, from which it appears that the Chinese possess a coloring substance having the appearance of indigo, which communicates a beautiful and permanent sea green color to mordants of alumina and iron, and which is not a preparation of indigo, or any derivative of this dyeing principal. As furnished to M. Persoz by Mr. Forbes, the American consul at Canton, it was in thin plates of a blue color, resembling Japanese indigo, but of a finer grain, differing also from indigo in its composition and chemical properties. On infusing a very small quantity of it in water, this fluid soon acquired a deep blue colour with a greenish tinge; upon boiling and immersing a piece of calico on which the mordants of iron and alumina had been printed, it was dyed a sea green color of greater or less intensity according to the strength of the mordant—the portions not coated remaining white.—*Fortune.*

(6494) POMPHRET. Stromateus. *Linn.* This fish is very abundant on the Tavoy coast, and in a smooth sea may be seen deep in the water in great numbers, but they are very shy of the hook. They are considered one of the best fish for the table.—*Mason.*

(6495) POMPHRET. Stromateus Argenteus. Fish.

Vowal meen, Tam. | Hulva mahie, Duk.

Ains. Mat. Med. p. 155.

(6496) PONDIGUL SLATE, a dark black monumental marble is procurable in any quantity at the village of Pondigul, distant from Masulipatam about 70 miles, and from Hyderabad about 90 miles, situated on the Guntoor side of the river Kistnah, and in the Guntoor district. Slabs from 5½ feet by 3 feet and from 2 inches thick are to be had at but little cost and labour, and there are good bandy roads in most directions, but the cheaper and more feasible mode of conveyance would be, on flat-bottomed boats or rafts down the Kistnah to Masulipatam, from whence it could be shipped to all parts. J. S. Stricke, P. A. A.—*Kimedy, 9th August* 1850.

(6497) PONERA (Latrelle), a genus of Insects belonging to the family *Formicidæ*. In this genus the neuters and females are armed with a sting. The peduncle of the abdomen is formed of a single knot; antennæ in these individuals thickened at the tip; mandibles triangular; head subtriangular. *P. contracta* is a small species, a native of England.—*Eng. Cyc.*

(6498) PONGAMIA. Of this genus Dr. Wight gives Pongamia elliptica, 420; glabra, 59; ovalifolia, 328.

(6499) PONGAMIA ARBOREA. From the seeds of the Pongamia glabra or Galidupa arborea, a honey-brown and almost tasteless oil is procured, which is fluid at common temperatures, but gelatinises at 55 degrees.—*Simmonds.*

(6500) PONGAMIA ATROPURPUREA; dark-purple pongamia. This tree is very common about Maulmain, and though vastly inferior to a multitude of others, Wallich thought it of sufficient beauty, to give it a place among his splendid engravings of rare Indian plants.—*Mason.*

(6501) PONGAMIA GLABRA. Indian Beech.

Poonga, Tam.	Hongay, Can.
Canaga, Tel.	Karung, Burm.

A graceful tree, and excellent for avenues: in good soil it attains a large size, has beautifully varnished green leaves all the year round; is valuable as a strong manure, for sugar-cane especially; requires no care.—*Dr. Cleghorn.* This large tree, attaining a height of 40 to 50 feet, is very common in S. India, flourishing equally well in the arid plains of the Carnatic, and on the Sub Alpine tracts of Mysore. Oil is made from the seeds. Roxburgh says the wood is light, white and fit for a variety of purposes. In Coimbatore it is used chiefly for fuel. The boughs and leaves are extensively used as manure. Wight No. 78, Travancore, 388, Bangalore, 55.—*M. E. J. R.*

According to Wallich, this, the karung oil tree, is indigenous in Amherst Province. The Burmese make an oil from this tree which may be the tree referred to by Wallich.—*Mason.* The wood said to be only fit for fuel Roxburgh on the contrary states that it serves for a variety of purposes. An oil is expressed from the seed.—*Rohde.*

(6502) PONTEDERA DILATATA. This much larger species is found in the neighborhood of Rangoon, and may exist in the Tenasserim Provinces.—*Mason.*

(6503) PONTEDERA VAGINALIS. PONTEDERA. The margins of many wild jungle streams in Tenasserim, are pimpled with a small species of the pontedera. It is

> "A bonnie wee flower all wild in the wuds,
> Like a wee twinkling star high up in the cluds,
> Which opens its cups sealed up in the dew,
> And spreads out its leaves of a beautiful blue."—
> *Mason.*

(6504) PONTEDERACEÆ, *Pontederads*, a natural order of Plants belonging to the class of Endogens. It has a 6-parted tubular coloured perianth, more or less irregular, with a circinate æstivation. The stamens arising from the calyx 6 or 3 opposite the petals, the anthers turned inwards, opening lengthwise. The ovary is free, more or less completely, 3-celled, many-seeded; one style, the stigma simple. The capsule 3-celled, occasionally acquiring an adhesion to the perianth, 3-valved with loculicidal dehiscence; the seeds are indefinite, attached to a central axis; ascending hilum small; the embryo with its radicle rather enlarged, orthotropal in the axis of somewhat mealy albumen. The species aquatic or marsh plants. The leaves sheathing at the base, with parallel veins in the larger species, arrow-headed, cordate, or dilated. The flowers are either solitary or in spikes or umbels, spathaceous; frequently blue, sometimes yellow. The aquatic plants comprehended in this order are distinguished by the divisions of their flowers being rolled inwards after flowering, to which may be added mealy albumen and an indefinite number of seeds. They are natives exclusively of North and South America, the East Indies, and tropical Africa. Very little is known of their uses. Some of the species are employed by the native Indian practitioners in liver complaints and diseases of the stomach. Rubbed down in butter and drank, they are said to remove redness of the eyes; powdered and mixed with sugar, to relieve asthma; and when chewed, to remove tooth-ache; brayed with milk, some are adminstered in fever and some eaten as pot-herbs.—*Eng. Cyc.*

(6505) PONTOPHILUS, a genus of Shrimps. (*Egeon*, Risso.)

(6506) POOAH OR POEE FIBRE. *Kienki*, by the Lepchis: and *Yenki* by the Lomboos. *Boehmeria frutescens*; grows to the height of six or eight feet: and the fibre when properly dressed, is quite equal to the best flax of Europe, used for fishing nets, game bags; twine and ropes. It is considered well adapted for making cloth and canvas, it has great strength and endures wet well. Occurs near Simla. Boehmeria frutescens furnishes the well known Pooah fibre, or Pooah Hemp. It is called "Pooah" by the Parbuttias, "kienki" by the Lepchis; and "yenki" by the Limboos. It is not cultivated, but grows wild and abundantly in the valleys throughout the mountains of Eastern Nipal and Sikkim, at the foot of the hills skirting the tarai to the elevation of 1000 or 1200 feet and within the mountains up to 3000 feet. Dr. Falconer recognised this plant, as common from Gurhwal to the Sikkim hills; from the Ganges to Burrampooter. In the outer hills of Gurhwal Kumaon it is called Poee. It does not grow in the forest but is chiefly found in open clear places, and in some situations overruns the abandoned fields of the hill people, within the elevations which suit it. It sheds its leaves in the winter; throws them out in April and May; and flowers and seeds in August and September. The exact period altering of necessity with the elevation—*Royle, p.* 368. See BOEHMERIA.

(6507) POODEENA. Mentha Verticulata. Mint. See MINT.

(6508) POON-WOOD, OR PEON-WOOD, of Singapore is of a light porous texture, and light greyish cedar color; it is used in ship-building for planks, and makes excellent spars. The Calcutta poon is preferred. A species of *Calophyllum* is called *poona* in the peninsula of India, and C. angustifolium, Dr. Roxburgh says, is a native of Penang and of countries eastward of the Bay of Bengal, and that it yields the straight spars commonly called Poon, and which in those countries are used for the masts of ships.—*Tredgold.* The wood called poon brought from the East Indies, to Britain, very nearly resembles a dull coloured and greyish specimen of mahogany, and would be useful for any purpose to which such kind of mahogany is applicable; besides having a greater degree of strength and stiffness compared with its weight. Poon is used for the decks, masts, and yards of ships, and it appears to be well adapted for these purposes both by its strength and lightness. In respect to durability we have not been able to collect satisfactory information; its texture is porous, but uniform; and the mean weight of a cubic foot in the dry state is 405 lbs. taken from our specimens. The cohesive force of *poon* is from 10,000 to 14,700 lbs. per square inch, the mean weight of the modulus of elasticity for bars of an inch square is 1,689,800 lbs. The specific gravity, and the relative strength, stiffness, and resilient power compared with Riga fir, as 1000, from Mr. Fincham's experiments are, as under:—

Specific gravity.	Strength.	Stiffness.	Resilience.	
579	1380	1270	1400	Barlow.
647	1226	1230	1146	Fincham.
613	1303	1250	1273	Mean of both.

From whence it appears that it is superior to Riga fir in the properties required for most wood. The poon of commence, is said by Dr. Wight to be from the

Dillenia Pentagynia. Dilleniaceæ.

Rowadah Tel.

This is a large timber tree, a native of the Northern Circars; it flowers in March and April. *Roxb.—Rohde. M.S.S.* The similarity of native names between this and Calophyllum inophyllum led Dr. Wight to suspect some mistake. The wood of Dillenia pentagyna is said to be exceedingly strong, and very durable, even when buried under ground. A stately forest tree, common on the face of the W. Ghauts. Dr. Wight is satisfied that this is the tree which furnishes the Poon spars, D. pentagynia is a tall and calophyllum inophyllum a short stunted tree.—*Wight.*

(6509) POONAHLITE, a Mineral occurring crystallised in long slender crystals. Primary form a right rhombic prism Fracture uneven. Colourless. Hardness 5·0 to 5·5. Transparent, translucent. Lustre vitreous. Found in Poonah in the East Indies. The following is an analysis by Gmelin:—

Silica	45·120
Alumina	30·446
Lime	10·197
Soda, with a trace of potash	00·657
Water	13·386
	99·806

Eng Cyc.

(6510) POONGA or KURUNJ OIL.—Dalbergia Arborea or Pongamia Glabra.

Poonga yennai, Tam.	Kurunj ka tel. Hind.
Kanoogoo noona Tel.	

This oil, which in some parts of the country is used to a large extent in adulterating lamp oil, is expressed from the seeds of a tree, common in most parts of the Madras Presidency. In North Arcot, Bellary, and the Nuggur Division of Mysore, the oil is procurable at Rs. 2-8-0 per maund. It is chiefly used as a Lamp oil by the poorer classes.—*M. E. J. R.*

(6511) POONEER.

Pooneer, Tam.

This is a very light white coloured earthy matter containing a great proportion of Carbonate of Soda, and from which, as well as from Over Munnoo, soda is prepared. Pooneer is employed in making glass, in dyeing blue and scarlet and also by the Chucklers in dyeing leather red.—*Ains. Met. Med. p.* 192.

(6512) POOTROONGIE, A new Oil.

(6513) POVERASIE, *Tam.*

Santa Maria, Port.

And called by Europeans Ceylon Tulip-tree. It is used at times by the coachmakers for wheels, &c. It is a tree generally planted to ornament walks in gardens, and is very common: it produces a yellow flower.—*Edye. Ceylon.*

(6514) POOVATHOO, a substance used in dyeing.

(6515) POPLAR,

Popelier, Dut.	Pioppa, It.
Peuplier, Fr.	Populus, Lat.
Pappel, Pappelhaum, Ger.	Alamo, Sp.

A fast growing tree (*Populus*), of which there are about fifteen varieties. The wood is soft and light, and not very durable, unless kept dry. It is used in the manufacture of domestic utensils, water-works, laths, and packing cases.—*Faulkner.*

(6516) POPPY OIL. Papaver somniferum.

Cas-cas Yennai, Tam.	Khush-khash-ka Tael,
Casa-casa Noona, Tel.	Hind.

The poppy is largely cultivated throughout Malwa and the Opium districts, where the drying oil obtained from the seed is more extensively used than any other, both in lamps and as food. At Bhopaul the oil is procurable at the rate of Rs. 4 8 0 per maund of 25lbs. or £40 6 per ton. By simple exposure to the rays of the sun in shallow vessels, this oil is rendered perfectly colourless, and a very excellent sample of the bleached article exhibited by Lieut. Hawkes received Honorable Mention. It is much prized by European artists.*M.—E. J. R.*

(6517) POPPY SEED, Cuscuss Seed, Maw Seed.

Gaysaggusa, Can.	Kushkush, Arab.
Ying suh, Chin.	Papavero, It.
Abinatta, Cyng.	Kes, Jap.
Capsules des pavots blancs, Fr.	Kush-kush, Kooknar, Pers.
Die kopse des weissen mohns, Ger.	Post, Chosa, Sans.
Cuscuss, Guz. & Hind.	Casa-casa, Tam.
	Cassa-cassa, Tel.

The seed of a most important plant (*Papaver somniferum*), a native of the South of Europe and Asia Minor, and now naturalized by cultivation in India. Poppy seeds are employed in medicine for the preparation of a sedative decoction and syrup. In India they are used by the natives in sweetmeats, and by some classes of the Hindoos at some of their festivals. Poppy seeds are exported from Bombay to England and France.—*Faulkner.*

(6518) POPULUS (from the Latin *Populus*), a genus of Plants belonging to the natural order *Salicaceæ.—Eng. Cyc.*

(6519) POPULUS FASTIGIATA, the Lombardy Poplar. Leaf deltoid, wider than long, crenulated, glabrous, in the bud involutely folded, petiole compressed. This tree is readily distinguished among the species by its peculiar conical cypress like form, and the total absence of horizontal branches. It grows to the height of 100 and 120 feet, and sometimes 150 feet. It is a native of Italy on the banks of the Po, and also of Persia and the Himalaya.—*Eng. Cyc.*

(6520) PORANA. Of this genus Dr. Wight gives, Porana *paniculata*, 1376; racemosa, 1376; volubilis, 347-1376.

(6521) PORANA VOLUBILIS; BHOWREE, *Hind.*—A twining plant, flowers white, in axillary and terminal racemes; propagated by seed; requires no particular soil.—*Riddell.*

(6522) PORCELLANIDÆ, a tribe of Anomurous *Crustacea*, placed by M. Milne-Edwards next to the *Paguri*, and immediately preceding the section of Macrurous Decapods.—*Eng. Cyc.*

(6523) PORCELLANA (Lam). The general form resembling that of the *Brachyura*.—*Eng. Cyc.*

(6524) PORCELLANA SCULPTA. Colour reddish with great white spots. Length about three lines. It inhabits the coasts of Java. Two others species are recorded, one of them from the China seas: the other is *P. viridis*, Gray, 'Zool. Misc.' *Pisidia viridis*, Leach.—*Eng. Cyc.*

(6525) PORPHYRY. Felspar of a granular texture, without crystals imbedded, is Claystone; with imbedded crystals of felspar it is Porphyry. Hornblende mixed with uncrystallised felspar makes some Greenstones; with imbedded crystals of felspar this becomes Greenstone-Porphyry. Hence, by this mode of designation, we have Pitchstone-Porphyry, Greenstone-Porphyry, Basaltic-Porphyry, Felspar-Porphyry, andeven so vague a term as Trap-Porphyry; and, on the other hand, more correctly, Porphyritic Pitchstone, Porphyritic Claystone, Porphyritic Greenstone, Porphyritic Basalt, and Porphyritic Granite. Among volcanic rocks, Porphyritic Trachytes are common. Fine examples of porphyry (crystals of felspar in a base of uncrystallised felspar) occur in Scotland, at Inverary and in Ben Nevis; in Cumberland, on Armboth Fell; and in Cornwall, commonly under the title of Eurite.—*Eng. Cyc.*

(6526) PORCELAIN.

Tse-ki, CHIN. | Chenee-kan, GUS. HIND.

A very fine species of earthern-ware, white, semi-transparent, and sometimes beautifully coloured and gilt. Chinese porcelain, which is of an exceedingly fine texture, has long been renowned; but British porcelain, although unable to boast of such fine specimens of costly workmanship, has risen to be a matter of great importance. Dresden has long been famous for the beauty of its porcelain productions; but the finest and most magnificent specimens of European china, have been produced at Sevres, in France. Sir John Davis has condensed all the important information concerning the materials and manufacture of porcelain,—a name given by the Portuguese to the semi-transparent cups they saw on their arrival, from their resemblance to the lustrous nacre of sea-shells, or *porcellana*, for they supposed it to be a composition of egg-shells, fish-glue, and scales—a good instance of the off-hand descriptions travellers formerly indulged in, just as Chinese writers now describe things new to them; as, for instance, when they call caoutchouc elephant's skin. The Kaolin or *Kau-ling*, i. e. High ridge, the name of a hill near Jauchau fu, is obtained from the disintegrated granite in that region, and is nearly pure felspar, or such as contains no metallic substance; by slow decomposition the alkali and part of the silex is removed, and water imbibed. An analysis of the clay used in Europe, which probably does not differ materially from that employed in China, shows the constituents to be silica 43, alumine 36, water 19, and a trace of magnesia and carbonate of lime. The petuntse, or *peh-tun-tsz*,' is nearly pure quartz, and the best is brought from Hwuichau in Nganhwui, but is procurable elsewhere; it is reduced to an impalpable powder by toilsome processes, and formed into cakes to sell to the manufacturers. Steatite or soap-stone called *hwah shih*, is also employed, and some forms of carbonate and sulphate of lime, which are mixed in to produce an inferior article, though still among the best now manufactured; the soap-stone ware is more brittle than the other, but fine, white, and very light. The proportions of the ingredients vary according to the desired fineness of the ware. After the paste or biscuit is thoroughly mixed and formed into the required shape, the dishes are painted by workmen, each of whom takes a single color and a single part of the picture. The whole surface of the dish is sometimes covered with gay figures, but the most common decorations consist of heroes, statesmen, &c., in different attitudes and costumes, and sentences beautifully written referring to them and their times. Most of the inscriptions and figures seen upon mantel-piece ornaments, tea-cups, and jars, are of this nature, explaining some event in the life, or a panegyric upon the personage there represented; this affords an opportunity for persons to show their scholarship in explaining the quotation.—*Williams' Middle Kingdom, Vol.* II *p.* 116. The colors used on the fine porcelain have long been admired, and Deguignes, who made many endeavours to procure samples of them and ascertain the mode of mixing them, has given the composition of

some of the principal colors, but at present there is probably little to learn from them in this branch. After the workmen have finished the painting, the pieces are covered with a liquid mixture of alkali, obtained from burning ferns with the quartzose petuntse, after which they are baked. The best articles are surrounded with a case lined with sand in order to protect them from the flame, and as the furnaces are only about six or eight feet square, the closest attention can be paid to the condition of the ware, and the exact time ascertained for reducing the heat and opening the kiln. Some of the pieces brought from the interior are perfectly white, and the patterns are afterwards painted and fixed on them according to the fancy of the customer. The finest specimens are from the kilns of Kingtch-chin in Kiangsi.—*Williams' Middle Kingdom, Vol.* II. *page* 117.

(6527) PORCUPINE: HISTRIX LEUCURUS. Large Porcupine. A large porcupine is not uncommon in Tenasserim, but the precise species is not known. It is probably identical with one of the Malay species. The one found in Arracan is the common Indian species, and that of Tenasserim, may possibly be the same.—*Mason.*

(6528) *Histrix alophas?* Small Porcupine. There is a small porcupine in the Tenasserim Provinces, which does not appear to have been discovered in Arracan. According to native description, it best accords with the small species described by Hodgson.—*Mason.*

(6529) PORTIA TREE OIL. Thespesia populnea.

Poorasum yennai, Tam. | Paris pippul, Hind.

This deep red coloured and somewhat thick oil is obtained from the seeds of the portia tree, which grows in great abundance in the vicinity of Madras, and other parts of the Presidency. It is extensively planted as an avenue tree, for which its quick growth and the beauty of its flowers renders it a favorite. The wood is capable of being worked when fresh cut and is used for boat building and cabinet work. The juice of the tree is used on the western coast, as a remedy for various cutaneous affections, and the oil which is yet unknown to the natives, might probably be of use in similar cases. Its expense precludes its use otherwise than medicinally.—*M. E. J. R.*

(6530) PORTULACA OLERACEA. Lin.

Corie Keeray, Tam. | Loonia, Hind.
Pirapoo keeray, Tam.

Is common in India, and eaten by the Hindoos; in Cochin China, the seed is considered emollient and diuretic.—*Ainslie p.* 253, *O'Sh. p.* 353. A common weed; cultivated by the market gardeners; used as spinach and in curries; almost tasteless.—*Jaffrey.*

(6531) PORTULACA. PORTULACEÆ. These are pretty annuals with succulent leaves, and very brilliantly coloured flowers, red, purple, yellow, white, &c., they are easily grown from seeds, and if well watered and kept in the shade, will blossom throughout the hot season; the hybrids, between the white, and dark colours are remarkably pretty.—*Riddell.* This pretty little succulent annual, opens its flowers in the sun. It is raised from seed, requires a sandy soil. Is a native of the tropics; requiring little care as regards soil; should be watered, sparingly at all times.—*Jaffrey.*

(6532) PORTULACA QUADRIFIDA. Lin.

Possarie-keeray, also Posselie-keera Tam.
Choroly ke bauge, Duk.
Batsali koora, Tel.
Oppadykee, San.
Bucklut-ul mobarik Arab.
Chowlee, Duk.

Is fully described by Ainslie. The bruised fresh leaves are prescribed as an external application in erysipelas, and an infusion given in dysuria.—*O'Shaugh. p.* 353. A small troublesome weed with fleshy leaves, used as greens, common every where.—*Jaffrey.*

(6533) PORTUNIDÆ, a family of Brachyurous *Crustacea*, nearly allied to the Cancerians. The species are generally known by the name of Paddling Crabs. The general form of the *Portunidæ* does not ordinarily differ much from that of the greater part of the Cancerians; but the carapace is always but little elevated, and sometimes has a lozenge-shape. The Crustaceans of this group are for the most part essentially swimmers, and live often out at sea. They are vulgarly called Paddlers. The following genera are arranged under the tribe by M. Milne-Edwards:—

(6534) *Carcinus.* (Leach).
(6535) *Platyonychus.* (Latreille).
(6536) *Polybius.* (Leach).
(6537) *Portunus.* (Fabr).
(6538) *Portunus integrifrons,* (Cancer Navigator (?). Herbst) Carapace pubescent: length about 2 inches. It is a native of the Indian Ocean.
(6539) *Lupea,* (Leach).
(6540) *Lupea tranquebarica.* (Cancer olivaceus, Herbst: C. Serratus (?) Forsk. Portunus Serratus R. Ruppell; P. Tranquebaricus, Fabr. This, the largest portunian known, is six or eight inches in length, of a grayish green and inhabits the seas of Asia.

(6541) *Lupea pelagica.* (Cancer Pelagicus Linn. Cancer reticulatus and Cancer Cedohulli Herbst: Portunus pelagicus, Fabr. Length from three to four inches. Colour grayish-green with yellow spots, found in the Red Sea and the whole Indian Ocean.—*Eng. Cyc.*
(6542) *Lupea sanguinolenta.* Indian Ocean.
(6543) *Platyonychus* (Latreille).
P. bipustulatus. Length from two to five inches. It is found in the Indian Ocean.
(6544) *Portunus* (Fabr.).

(6545) POST, *Hind.* Post, which, properly speaking, is the Sanscrit and Hindoostanee name of the Poppy, Papaver somniferum, is also an appellation given, in the higher provinces of India, to an intoxicating liquor, prepared by beating the husks or capsules of the Poppy with Jaggery and water.—*Ainslie's Mat. Med. p.* 267.

(6546) POTASH, CARBONAS POTASSÆ IMPURUM.

Mara Ooppoo, TAM.

Impure Carbonate of Potash. *Potashes. Pearl-ashes.* This is prepared on the great scale by subjecting to the action of flame crude or black Potash, the *black salt* of American manufacturers. Instead of fusing it to make the *Potashes* of Commerce, the alkaline mass is transferred to a large oven-shaped or reverberatory furnace, where the flame is made to play over it; and being well stirred about, the black impurities are burnt out, and the mass becomes a caustic salt of a white colour (W. and B.) with a tinge of blue, and constitutes the *Pearlash* of Commerce. American Potash and American Pearlash (2), as ascertained by Vauquelin, contained in 1152 parts.

Caust. Hydr. of Potash.	857	Sulph. of Potash.	154	Chlor. of Potash.	20	Insol.	9	Carb & Aq.	110	parts.
(2)	384	„	80	„	4	„	6	„	688	„

Russian Potash yields 772 parts of Caustic Hydrate; it used to be very impure, but is now more carefully prepared. For commercial purposes it is extremely necessary to have modes of ascertaining the quantity of alkali contained in any specimen of Commercial Potash. This is done by the process of Alkalimetry.—*Royle.* The Hindoos on the Malabar coast, as well as the Cingalese, who do not use over Munnoo (Impure Carbonate of Soda); in bleaching and washing linen, employ for these purposes, the ashes of burnt vegetables (chiefly Cocoanut leaves), which can only, in this way, be of service, from the Potash they contain.—*Ains. Mat. Med. p.* 193.

(6547) POTASH, CARBONATE OF; *Subcarbonate of Potash. Salt of Wormwood. Kali præparatum. F.* Carbonate de Potasse. *G.* Kohlensaures Kali. Potash, Salt of Tartar, Salt of Wormwood.

Potaske, DAN.	Potassa, IT.
Jhar ke Nemuk, DUK.	Potasz, POL.
Potasse, FR.	Potasch, RUS.
Potasche, GER.	Marnoopoo, TAM.
Jowkshar, GUZ. HIND.	Manje oopoo, TEL.

A term commonly applied to an impure carbonate of potash, obtained by the incineration of wood, lixiviating the ashes in barrels, first with cold, and then with hot water, filtering the ley, and evaporating it to dryness in an iron pot. This constitutes the potash of commerce, which is in hard irregular masses or fragments, of a light bluish gray colour, somewhat caustic, alkaline taste, inodorous, and very deliquescent. Potash is of great importance in the arts, being used in the soap and glass manufactures, the rectification of spirit, bleaching, in medicine, and for other purposes. It is procurable in most Indian bazaars.—*Royle. Fleming.* This substance is of great importance but no manufacture of it upon an extensive scale has ever been attempted in India. The common source of it, is the ashes of land plants and the English market is supplied from Russia and America. If attention were directed to the manufacture of this Salt in India, it would form a very valuable article of export. A source of Pearl ash, and one very interesting to us, seeing the enormous quantities of Saltpetre all over the country, is Nitrate of Potass and Charcoal, a sample of Pearl ash from a refined Saltpetre got from the Gunpowder Manufactory, and the Gram-plant. Charcoal, also used in that establishment, was after one crystallization, superior to the best Russian or American article, giving by the alkalimeter 94 per cent of pure Carbonate.—*P.M.C.C.* As this salt is obtained by the burning of vegetables, it must have been known at very early times Dioscorides describes it by the name τεφρα̃ς σαρμάτων, or *cinis sarmentorum*, ashes of vine-twigs. (" cineris lixivium " Pliny, xxxviii. c. 51.) The Arabs are usually supposed to have been the first to make known this alkali (*al-kali*); but the Hindoos, in works from which the Arabs copied, made use of the ashes of plants. Potash is found in most of the alkaline earthy minerals, as Mica, Felspar, Leucite, Nacrite. Carbonate of Potash has been found in a few mineral springs. It is probably found in the juices of some plants. But usually Potash is combined with other acids, then forming Acetates, Malates, Oxalates, Tartrates, &c.

By incineration, the Oxygen of the vegetable acid, combining with the Carbon of the vegetable substance, forms Carb., which, combining with the disengaged Potash, forms a Carbonate of Potash. This, in its most impure state, is the Potash of Commerce, or Rough Potash of Commerce. To obtain this, land plants are burnt in countries where forests are most abundant, as N. America, Russia, Sweden, Poland. The wood is piled in heaps and burnt on the surface of the ground, in a place sheltered from the wind. " The ashes which are left consist of a soluble and insoluble portion. The *soluble* part is made up of the Carb. together with the Sulphate, Phosphate, and Silicate of Potash, and the Chlorides of Potassium and of Sodium; and the insoluble portion, of Carbonate and Sulphosphate of Lime, Alumina, Silica, the Oxides of Iron and Manganese, and a little carbonaceous matter that had escaped incineration." (Wood and Bache.) —*Royle.*

(6548) POTASSÆ BITARTRAS, L. E. D. TARTARUM, D. Bitartrate of Potash. *Supertartrate and Supertartrite of Potash. Cream of Tartar.*

Argol. *Fr.* Tartrate acide de Potasse. *Ger.* Doppelt Weinsaures Kali.

Bitartrate of Potash (KO, 2 Tar. Acid, HO = 189) is well known by the name of Tartar, and must have been known ever since wine has been made from the grape, in the juice of which it exists. During the fermentation of wine, Sugar disappears and Alcohol is formed, and the salt not being soluble in this, is deposited on the bottom and sides of casks, as a crystalline crust, which, according to the colour of the wine, forms either *red* or *white Tartar* or *Argol*. This was known to the ancients, and is the Fex Vini of Dioscor. v. c. 13. (Hindoo Med. p. 97.) Its nature was determined by Scheele in 1769. It is largely purified both at Montpelier and at Venice.

Prop. The Bitartrate of Potash of commerce is in white crystaline crusts, formed of clusters of small crystals aggregated together, which are hard and gritty under the teeth, dissolve but slowly in the mouth, and have an acid and rather pleasant taste.—*Royle*.

(6549) POTASH, NITRATE OF: KO NO_5. This salt, also named *nitre* or *saltpetre*, is a natural product, but may be prepared by the addition of nitric acid to potash, or to carbonate of potash. The liquor, on being evaporated, deposits anhydrous crystals, which are six-sided prisms with dihedral summits. This salt is soluble in 7 parts of water at 60°, and in its own weight of boiling water. It has a cooling and saline taste, but has no action on vegetable colours. It fuses at a temperature below redness, and is completely decomposed under a strong heat. When mixed with combustible matter and heated, or thrown in a fused state on many metals, rapid oxidation takes place at the expense of the oxygen of the nitric acid. Gunpowder is an example of such a mixture, and there are many such in various pyrotechnic compositions, which burn independently of the atmospheric air, and even under water, oxygen being abundantly supplied by the nitric acid. In India, Egypt, and some other warm countries, after the rainy season, nitre is produced on the surface of the soil in the form of a white efflorescence. The soil is removed to the depth of about an inch, and treated with water, which dissolves the soluble salts. The solution is made in large basins or tanks; rapid evaporation takes place under the influence of the solar heat, and is completed by means of artificial heat; as the solution cools, a considerable quantity of nitrate of potash is deposited in large crystals. This forms *rough Indian nitre*. The mother-liquor is thrown away; it contains a considerable quantity of nitrate of lime and magnesia, and might still furnish nitre if mixed with potash salts. Bengal and the neighbourhood of Patna are the sources of the largest portion of the saltpetre supplied to the European market from Hoogly, but the Madras Presidency furnishes large quantities of the best quality. In Hungary there are saltpetre pits, and in some parts of Spain the soil becomes incrusted with this substance. Nitre is also obtained from certain natural caverns occurring in the limestone rocks of the island of Ceylon: the walls become covered with a nitrous efflorescence, which is detached, during six months of the year, with picks, together with a small portion of the rock which contains felspar, and this is doubtless the origin of the potash. The fragments are pounded, mixed with an equal portion of wood-ashes, and water is poured upon the mixture. The nitrates of the earths part with their acid to the potash in the ashes, and the earths are precipitated as carbonates of lime and magnesia. The clear decanted lye, containing the nitre of the ashes as well as that of the rock, is evaporated in pits exposed to the sun, and then in pans by the action of fire. The crude saltpetre, which crystallizes in cooling, is then fit for exportation. Similar caves exist in Italy, on the coast of the Adriatic, in North America, Africa, Teneriffe, &c. In France, nitre was formerly produced artificially in what are termed *nitre-beds*, by the oxidation of ammonia in the presence of a powerful base. Animal refuse of all kinds was mixed with old mortar, or hydrate of lime and earth, and the mixture was placed in heaps under a cover of some kind, to keep off the rain, but with free exposure to air. The heaps were watered from time to time with stale urine, and the mass was turned over in order to expose fresh surface to the air. When a considerable quantity of the salt had been formed, the mixture was lixiviated, in troughs of oakwood.

The rough nitre as imported into Great Britain from the East Indies, is in broken crystals of a brown colour, and more or less deliquescent. The loss which it sustains in refining is termed the *refraction*, and can only be ascertained by analysis; but it is not easy to obtain a fair sample of a cargo. "The samples which the merchants and brokers select for analysis, generally consist of portions drawn from each bag and afterwards mixed together, and if carelessly or unfairly taken, or exposed so as to become more moist or more dry than the bulk, the report of the analyst is often unsatisfactory. He should work upon not less than 20 to 30 lbs. of such sample, which should be ground or triturated so as to produce a properly uniform mixture of the whole, for it often includes lumps of pure nitre or of other salts: from 100 to 1000 grains of this mixture is then taken for analysis. The moisture is determined by the loss occasioned by careful drying on the sand-bath: it is then dissolved in water and tested, so as to acquire some general notion of the impurities; and by means of nitrate of silver, nitrate of baryta and oxalate of ammonia, the proportion of chlorine, sulphu-

rie acid, and lime may be determined: the lime is generally in the state of sulphate, and more or less sulphate of potash is also usually present. The chlorine is chiefly derived from the chlorides of potassium and sodium. Another portion of the sample should be dissolved in about thrice its weight of boiling water and filtered, by which any sand or other insoluble impurities are collected: the salt should then be crystallized in the usual way, during which the appearances and forms of the successive deposits will indicate, to the experienced eye, the nature of the foreign salts present, among which nitrate of soda, sulphate of potassa, sulphate and nitrate of lime, and chloride of sodium and potassium, with traces of chloride of calcium, and sometimes of a peculiar organic matter, are frequently found. It will be obvious that the accurate quantitative analysis of such a mixture of salts is not a very easy problem; and yet the separation of nitrate of soda from nitrate of potassa, and of chloride of potassium from chloride of sodium, are essential steps, as the value of the sample is affected by their relative proportions: for nitrate of soda, to say nothing of its unfitness for the manufacture of gunpowder, is cheaper than nitrate of potassa; and chloride of sodium is of no value, whereas chloride of potassium is purchased by the alum-makers: so that a sample of nitre, containing the latter salt, is in this respect worth more than where it only contains common salt. But inasmuch as the equivalent of chloride of sodium is only 60, and that of chloride of potassium 76, it is obvious that if the whole of the chlorine, as indicated by the weight of the chloride of silver, be considered as in combination with sodium (part of the sample consisting of chloride of potassium), the refraction will be estimated below the mark. Hence the necessity of ascertaining the relative proportions of both chlorides, which is best effected by converting them into sulphates and separating them by crystallization."

The refining of nitre on a large scale is founded on the property that its solubility increases rapidly with the temperature, while the solubility of the chlorides of sodium and of potassium remains nearly constant. For example, about 25 cwt. of rough nitre is dissolved in a large copper boiler in 150 gallons of water; the heat is gradually raised, and fresh portions of nitre are added until about 60 cwt. have been dissolved. The solution is kept stirred, and the scum removed. The water in the boiler, when raised to the proper temperature, is sufficient to dissolve the whole of the saltpetre, but not the whole of the foreign salts: a large portion of the chloride of sodium solidifies, and may be scooped out of the boiler. 100 gallons of water are then gradually added so as not to cool the solution too much; 2½ lb. of glue dissolved in warm water are then poured in, and the whole thoroughly agitated. The glue thus diffused through the liquid becomes entangled with the organic substances which rendered the solution viscous, and rises with them to the surface in the form of scum, which is carefully removed; and after boiling for some time, the liquor becomes clear. The fire is then withdrawn and the temperature let down to about 195°, when the liquor is carefully dipped out and removed to the crystallizing vessels. The liquor must be disturbed as little as possible during this operation, in order not to suspend the crystals of common salt deposited at the bottom. The crystallizing vessel is a shallow copper vessel, the edge of which is firmly screwed to a platform of oak.—*Tomlinson.*

(6550) POTASSIUM.

Potassium, Fr. | Kalium Kali metall. Ger.

Is a soft malleable metal. It is silvery white, and immediately tarnishes when exposed to the air, from its great affinity for oxygen, which it will take also from water, swimming and burning upon it with great brilliancy, and being converted into potash while the hydrogen escapes. It is preserved in fluids, such as petroleum, naptha, &c., as they contain no oxygen.—*Royle, Faulkner.*

(6551) POTATOES.

Ruta inuala, Cyng.

Jabloki semlenne, Patata, Rus.
Patata, Sp.
Wallumi kilungoo. Tam.
Oorulay-gudda, Tel.

The roots of the Solanum tuberosum, of innumerable varieties.—*Faulkner.* Potatoes, are cultivated for the tubers attached to the roots. Those cultivated on the plains of India are hardly fit for human food, in consequence of their never arriving at maturity, they ought to succeed well on the hills; but wherever grown they will do little good if repeatedly planted on the same spot of ground, they require a change every year, propagated by division of the tuberous roots.—*Jaffrey.* This vegetable is now generally cultivated all over the Deccan, but was a few years ago confined to Surat and Seroor. The former was generally the finer, and could only be had during the cold season; but now the potatoes are grown all the year round on the Neilgherry and Mahabuleshwar hills, they are in abundance. They should be planted in rows about one foot apart, and five or six inches deep; the space between each row, if ground can be spared, eighteen inches, otherwise a foot. The ground should be light and loamy, and as little infested with white ants as possible. They can be sown at the commencement of the rains, and a spot should be selected where the water cannot lodge, but be easily let off; which may be done by keeping the end of the channel

between the ridges open. At this season, plant your potatoes on the top of the ridges, and do not water them unless necessary, as too much water makes them run to stalk. If your ground has not been well ploughed previous to the rains setting in, and all the weeds destroyed, the chance is your crop will fail; but should you have your ground ready, take your potatoes, intended for seed, and cut them into pieces, taking care that each slice has at least two eyes in it; and as you cut the slices, whilst fresh, dip the cut side of each into wood-ashes, and let them dry well, which takes place in a few hours: this prevents the white ant's attacks. Sow each slice from nine to twelve inches apart, and place by the side of each a small clove of garlic, which in some measure tends to prevent the attack of a large grub very destructive to the plant. Dr. Riddell thinks this insect's eggs must be in the manure when added to the soil, and has little doubt but that if the manure was previously worked up with the soil two or three times during the hot season, and exposed to the heat of the sun, the eggs would be destroyed: or the same purpose might be effected with a little fresh lime. He is sure the caterpillar does not travel to the plant.

The finest crops in the Deccan are sown from the beginning of October to the latter end of December, and this last crop will be found the most productive. Fine crops of potatoes have been grown where hemp has been first sown, and when about two feet high ploughed up into the ground. If, when your potatoes are about flowering, you perceive any of the stalks wither, carefully open the earth and look for a grub, which you may be certain is feeding upon it—of course destroy it. When these grubs are very numerous, it is necessary to search all the drooping plants daily: his idea is, that the larvæ is brought with the manure, and is the deposit of a beetle—however, nothing can be done but destroying them. He has heard recommended a bag with a small quantity of assafœtida to be placed in the water-course, as a remedy, when the plants were being irrigated. Another insect deposits its egg on the stalk of the plant. In the rains a small caterpillar eats its way into the stalk above the ground, when the plant immediately droops: the remedy is to remove the whole. Be careful at all seasons to keep the stalks well earthed up, and let the potatoes have a moderate supply of water—of course the season must be your guide. He, one year, at Kumhur, raised a very fine crop of potatoes during the rains, by sowing them on ridges, and only watered them at first, in consequence of want of rain: they were sown in the beginning of July, and a few taken up in September (the latter end). Some of the potatoes weighed from five to seven ounces, and were equal to any seen grown on the Hills. In the latter end of August, by way of exprtiment, he tore off shoots from the lower end of the stalks, when they were abundant, and planted them in rows, the same distance as for seed; and in November, on taking them up, was gratified by finding four or five large potatoes produced by each stalk, the size of a duck egg. This plan he strongly recommends to those persons who may not be able to get fresh seed after the rains. He did not find that the rows of potatoes from which the slips were taken produced fewer potatoes in consequence, as he weighed the whole and kept a memorandum in his journal.—*Riddell.*

Amongst tuberous rooted plants, which serve as food for man in various quarters of the globe, the principal are the common potato, yam, cocoes or eddoes, sweet potatoes, taro, tacca, arrowroot, cassava, or manioc, and the Apios (*Arracacha esculenta*). There are others of less importance, which may be incidentally mentioned. The roots of *Tropæolum tuberosum* are eaten in Peru, those of *Ocymum tuberosum* in Java. In Kamschatka they use the root of the *Lilium Pomponium* as a substitute for the potato. In Brazil the *Helianthus tuberosus*. The rhizome and seed vessels of the Lotus form the principal food of the aborigines of Australia. Many other plants and roots, furnish farinaceous substance and support in different countries. The comparative amount of human food that can be produced upon an acre from different crops, is worthy of great consideration. One hundred bushels of Indian corn per acre is not an uncommon crop. One peck per week will not only sustain life, but give a man strength to labor, if the stomach is properly toned to the amount of food. This, then, would feed one man 400 weeks, or almost eight years! 400 bushels of potatoes can also be raised upon an acre. This would give a bushel a week for the same length of time; and the actual weight of an acre of sweet potatoes (*Convolvulus batatas*) is 21,344 lbs., which is not considered an extraordinary crop. This would feed a man (six pounds a day) for 3,557 days, or nine and two-third years! To vary the diet we will occasionally give rice, which has been grown at the rate of 93 bushels to the acre, over an entire field. This, at 45 lbs. to the bushel, would be 4,185lbs.; or, at 28 lbs. to the bushel when husked, 2,604 lbs., which, at two pounds a day, would feed a man 1,302 days or more than three-and-a-half years! The common English or Irish potato (*Solanum tuberosum*), so extensively cultivated throughout most of the temperate countries of the civilised globe, contributing as it does to the necessities of a large portion of the human race, as well as to the nourishment and fattening of stock, is regarded as of but little less importance in Britain's national economy than wheat or other grain. It has been found in an indigenous state in Chili, on the mountains near

Valparaiso and Mendoza; also near Monte Video, Lima, Quito, as well as in Santa Fe de Bogota, and more recently in Mexico, on the flanks of Orizaba. Notwithstanding its utility as a food had become better known, no high character was attached to it; and the writers on gardening towards the end of the seventeenth century, a hundred years or more after its introduction, treated of it rather indifferently. "They are much used in Ireland and America as bread," says one author, "and may be propagated with advantage to poor people." The famous nurserymen, London and Wise, did not consider it worthy of notice in their "Complete Gardener," published in 1719. But its use gradually spread as its excellencies became better understood. It was near the middle of the last century before it was generally known either in Britain or North America, since which it has been most extensively cultivated. The period of the introduction of the common potato into the British North American colonies, is not precisely known. It is mentioned among the products of Carolina and Virginia in 1749, and by Kalm as growing in New York the same year. The culture of this root extends through the whole of Europe, a large portion of Asia, Australia, the southern and northern parts of Africa, and the adjacent islands. On the American continent, with the exception of some sections of the torrid zone, the culture ranges from Labrador on the east, and Nootka Sound on the west, to Cape Horn. It resists more effectually than the cereals the frosts of the north. In the North American Union it is principally confined to the Northern, Middle, and Western States, where, from the coolness of the climate it acquires a farinaceous consistence highly conducive to the support of animal life. It has never been extensively cultivated in Florida, Alabama, Mississippi, and Louisiana, probably from the greater facility of raising the sweet potato, its more tropical rival. Its perfection, however, depends as much upon the soil as on the climate in which it grows; for in the red loam, on the banks of Bayou Bœuf, in Louisiana, where the land is new, it is said that tubers are produced as large, savoury, and as free from water as any raised in other parts of the world. The same may be said of those grown at Bermuda, Madeira, the Canaries, and numerous other ocean isles. The chief varieties cultivated in the Northern States of America are the carter, the kidneys, the pink-eyes, the mercer, the orange, the Sault Ste. Marie, the merino, and Western red; in the Middle and Western States, the mercer, the long red, or merino, the orange, and the Western red. The yield varies from 80 to 400 bushels and upwards per acre, but generally it is below 200 bushels. Within the last ten years an alarming disease, or "rot," has attacked the tubers of this plant, about the time they are fully grown. It has not only appeared in nearly every part of America, but has spread dismay, at times, throughout Great Britain and Ireland, and has been felt more or less seriously in every quarter of the globe. To the greater uncertainty attending its cultivation of late years, must be attributed the deficiency of the United States crop of 1849, as compared with that of 1839. This is one of the four agricultural products which, by the last census, appears smaller than ten years since.—("American Census Reports for 1850.") The crops in Ireland, where the potato is the principal object of culture, vary from 1½ to 10½ tons per acre, according to the season; but in the average of three years ending 1849, the annual growth of Great Britain and Ireland amounted to nine million tons, which, at £3 per ton, exhibits the value at £27,000,000 sterling. Ireland produced in 1847 a little over two million tons, the yield being 7¼ tons per acre. In 1848 the produce was 2,880,814 tons, averaging only four tons to the acre. In 1849, 4,014,122 tons, averaging 5½ tons to the acre. In 1850, 3,954,990 tons; and in 1851, 4,441,022 tons; the average yield per acre not stated. In many parts of Scotland 24 tons to the acre are raised. The sales of potatoes in the principal metropolitan markets exceed 740,000 tons a year, which are irrespective of the sales which take place at railway stations, wharfs, shops, &c. The imports into the United Kingdom average about 70,000 tons annually. Potatoes are exported to the West Indies, Mediterranean, and other quarters. For emigrant ships, preserved or dried potato flour is now much used. Thoroughly dried potatoes will always produce a crop free from disease. Such is the positive assertion of Mr. Bollman, one of the professors in the Russian Agricultural Institution, at Gorigoretsky. In a very interesting pamphlet, Les Moyens deprevenir la Maladie des Pommes de Terre. Experiences et Conclusions de A. N. C. Bollman, Conseiller d'etat, Professeur, &c. 8vo, St Petersburg, 1853. By this gentleman, it is asserted as an unquestionable fact, that mere drying, if conducted at a sufficiently high temperature, and continued long enough, is a complete antidote to the disease.—*Simmonds.*

(6552) POTEE, round red cakes of cotton; The inferior kind is impregnated either with the red colouring matter of the prickly pear, a better kind is made by impregnating the cotton with the kaysur flower, the weeping Nyctanthus, *N. arbortristis*, but the best is from the Safflower, *Carthamus tinctorius*. The Potee forms a ready and durable substitute for red ink.

(6553) POTENTILLA. Of this genus, Wight gives Potentilla Leschenaultiana, 996; Mooniana, 232.

(6554) POTENTILLA ATROSANGUINEA. These are herbaceous plants, and handsome

when in flower, they grow in any garden soil, the colours are various, and easily raised from seed, or by dividing the roots, the shrubby species grow from two to three feet high.—*Riddell.*

(6555) POTENTILLA DENTICULOSA, is common in the plains of Northern India in the cold season, and at elevations of 4000 to 5000 feet in the Himalayas; two other species are found in the Neilgherries—*Royle, page* 202. *O'Shaughnessy, p.* 325.

(6556) POTENTILLA OFFICINALIS. Roxb. Fl. Ind. i. p. 431. Syn. Sciudapsus Officinalis.

Vushira, Sans. | Guj-pipul, Beng.

A large creeper, the fruit cut in thin transverse slices is the *guj-pipul* of the bazars, and highly esteemed as a stimulant tonic.—*O'Shaughnessy, p.* 626.

(6557) POTENTILLA TORMENTILLA. *Πεντάφυλλον μελαν, Dioscr.* and *Theopr.* A native of Europe, and officinal; the root is very rich in tannic acid.—*O'Shaughnessy, p.* 325.

(6558) POTHOS. Wight gives Pothos decursiva, 770; heterophylla, 777; officinalis, 778: peepla, 780; pertusa, 781; scandens, 776;

(6559) POTTA DELL. A soft, coarse, open-grained, light Ceylon wood.

(6560) POTTERY, *Encaustic Tiles, Cements.* The art of fashioning clay into vessels of a variety of shapes, and hardening it by the action of heat, is one of the most ancient of the arts. Fragments of pottery are everywhere found among the ancient cities of India, as in those of other parts of the world; pottery, as Brogniart has remarked, affording the best record of the early ages of man, as bones do of the earth.—*Royle, Arts &c. of India page* 476. So little is known of Indian pottery that it is usually described as being hemispherical in shape. Some of it is no doubt so, for the convenience of being carried on the head; but it is a fact, that in the recent exhibition of Indian pottery, numbers of the best judges have greatly admired its elegant, even classical gracefulness of form. It is also stated to be black, and red, or yellowish. The clays which are generally employed in the more populous part of the country, Dr. O'Shaughnessy has observed, "contain so much oxide of iron and carbonate of lime that the vessels melt into a slag at a temperature little above that of redness." "Deposits of a black stiff clay, containing much vegetable matter, occur in some districts; vessels made with it sustain a higher temperature." Clays capable of bearing great degrees of heat have, however, been discovered in different parts of India. As one great object is to have porous vessels for cooling water, the ordinary clays answer sufficiently well for this purpose; and some of the forms, as that of the tortoise shaped, expose a larger surface to the air. The Hindoos, moreover, never use a vessel the second time, so no great expense will be incurred by them; thus encouragement is wanting to improve the nature of their pottery. But very successful experiments have been made to make improved pottery in India, as by Mr. Julius Jeffreys, the ingenious inventor of the respirator, who succeeded in making stone ware, soda-water bottles, crucibles, fire bricks, tiles, &c., which seem to have been glazed by the silica uniting with the alkaline ashes of the furnace. Dr. O'Shaughnessy greatly improved the pottery in use in the dispensary of Calcutta, and which he glazed with the borate of lime. The glazed pottery of Pegu, of which two very large jars were sent, has long been known for its glaze not being affected by acids. Dr. Hunter sent some excellent specimens of pottery from the School of Arts at Madras, and for which a prize was awarded. The ancient potter's wheel is the instrument with which the Hindoo works; and while it revolves, with the aid of his naked hands he fashions vessels of elegant forms, many of which have been admired as being of classical shapes, and some would appear almost as if they were of Etruscan origin: but there is no reason to believe that the Hindoos have ever had any thing but their own unerring taste to guide them. This beauty of form is equally conspicuous in the pottery of Sewan near Patna, as in that of Azimgurh or of Ahmedabad, of Mirzapore, or of Moradabad.

Some of it is remarkable, also, for its extreme thinness and lightness, showing the great skill of the artist, and making it difficult to understand how it kept its shape when in a plastic state, as I cannot learn that the turning-lathe is used to give a finish to any of the articles. The painted pottery of Kotah, and the gilt pottery of Amroha, have also been admired. The handles and the various ornaments of the Ahmedabad pottery are no doubt attached, as in Europe, by means of slip. From the specimens of basket-work pottery sent, there is no doubt that, with better materials and a little instruction the natives could excel in this as in the forms of their pottery. If we had no other information, we might yet infer from the crucibles employed by the goldsmith, by the workers in brass, and by the makers of cast steel, that some very infusible clays are to be found in India; but recent investigations have proved that crucibles and firebricks, superior in infusibility to those made of Stour-bridge clay, have been made in India; and from the white goblets of Arcot, and the light-coloured pottery of Madras, as well as from the white bricks sent from the Ceded Districts, we see that there are many useful clays without the usual admixture of iron.—*Royle, Arts &c. of India page* 478. As connected with pottery might be mentioned the variously coloured *Encaustic* tiles, which have been used for the domes of some of the tombs

near Delhi and Agra, as well as in Southern India; but I cannot learn that the art is at present practised. It was probably introduced by the Mahomedans from Persia.

The art of making *pottery*, or vessels of baked earth, is so ancient and so universal that we seek in vain for any precise information as to its origin. It is alluded to in that most ancient record, the book of Job, and is also repeatedly mentioned in other parts of the Scriptures. The potters of Samos were celebrated in the time of Homer; and great quantities of pottery have been found in Egyptian tombs, which, to all appearance, have lain unopened since the time of the Pharaohs. The earliest use of pottery was doubtless that of ordinary drinking vessels; but there was also a religious employment assigned to earthen vessels, which has been the means of preserving them for the inspection of after generations. In vases of baked earth the ashes of the dead were frequently deposited, and even where the practice of burning the dead was not followed, still various earthen vessels have been found placed at the head and feet of the skeleton, and sometimes hanging on pegs along the sides of the tomb. Thus among many distant nations, having different languages, manners, and superstitions, pottery was considered a necessary part of the furniture of tombs. The potter's art is extremely valuable in an antiquarian point of view. While metal is liable to corrosion, and wood to decay, pottery remains almost unalterable, and has thus been the means of discovering to later ages many points respecting the history, religion, customs, and manners of the ancients, which must otherwise have remained unknown. The potter's art is represented in all its stages of the tombs of Thebes. The mixing of the clay was effected by kneading with the feet; after which a mass of convenient size was formed with the hand, and placed on a wheel of very simple construction, and turned with the hand. During its revolution the forms of the vessel were made out with the finger; the handles were afterwards affixed; the objects were placed on planks to dry, then carefully arranged in trays, and carried to the oven. Ornamental designs were traced with a wooden or metal instrument previous to the baking. There is a general agreement in the nature and uses of ancient pottery, but at the same time a distinctive character belonging to each country and nation. In this distinctive character consists the value of pottery in an historical point of view. The rude and simple urns of the early inhabitants of these islands; the more carefully fashioned pottery of the Romans with which our country abounds; the simple unglazed earthenware of ancient Greece; the more elaborate forms called Etruscan, of which the finest specimens are, however, attributed to the Greek potters of the Isle of Samos, so celebrated for the delicacy and perfection of their workmanship; the red and black potteries of India; the black and white potteries of North America, the latter interspersed with fragments of bivalve shells; the irregularly formed and fanciful pottery of South America;—all these possess a distinct individuality which makes them clearly recognisable by the student of this interesting art, while it reveals many valuable facts, taken in connexion with the localities in which they are found, their greater or less simplicity, their modes of ornamentation, and the relics which they frequently enclose. On the discovery of the extraordinary ruins of Mitla and Palenque, in Mexico, not many years ago, numerous specimens of pottery were met with, of a remarkably advanced kind for the period assigned to those ruins, namely, one thousand years before the Christian era. These potteries, although made without the turning lath, are ornamented in different colours, well baked, and covered with a fine vitreous glaze, such as was unknown to Europeans until about ten centuries ago.

As other branches of art advanced, so the potter's art became more and more developed, until at last a very fine hard description of pottery, thin and translucent, was invented and manufactured under the name of *porcelain*, a word, according to some, derived from *porcellana*, the Portuguese for a drinking-cup; according to others, from the Italian word *porcellana*, a univalve shell, of the genus *cypræidæ* or *cowries*, having a high arched back like that of the hog (*porco*, Ital.), and remarkable for a white, smooth, vitreous glossiness of surface. This is the more probable derivation, since there is abundant evidence that the word *porcelaine* existed in the French language in the fourteenth century, and consequently anterior to the introduction of Chinese porcelain into Europe. Porcelain is of comparatively recent origin in Europe, yet it was commonly known in China more than a century before the Christian era. It was not until four or five centuries after that period, however, that fine materials were employed, and that some degree of perfection was attained. Still taking the later date, the porcelain of China as a high antiquity, and must have been made at least 1250 years before our English porcelain. When the Chinese had acquired a certain amount of skill and perfection, they appear to have rested entirely satisfied with the results, and to have continued producing them without variation for ages. So exclusively were the Chinese the manufacturers of porcelain, that it acquired the name of their land, and became universally known (on its introduction to Europe in 1518) as *China*. For a long period it was also erroneously supposed that the fine clay necessary for the production of good porcelain, consisting of silica and alumina in variable proportions, and called by the Chinese *kaolin*, was peculiar to their land, and that

consequently no country in Europe could hope to attain eminence in this manufacture.

The ceramic [*Κέραμος, potter's clay*, is supposed by some to be derived from *κεράννυμι, to mix up*. Others derive it from *κέρας* an animal's *horn*, used as a drinking-cup. Others, again, suppose it to be from *γῆ, earth*.] art, in its widest sense, includes the preparation of all articles in clay or argillaceous matters, which are submitted to the action of fire; so that a comprehensive treatise on the subject would include the manufacture of bricks and tiles, as well as of the choicest specimens of pottery and porcelain. The essential ingredients in every kind of clay, and, consequently, in every article in pottery and porcelain, are silica and alumina. [See CLAY.] The pure compound *silicate of alumina* is, it is true, an ideal type; since no clay, or artificially prepared pottery or porcelain paste, is ever free from admixture with other ingredients, such as iron, lime, potash, &c. If, however, we remove from the paste either the silica or the alumina, we render it useless for the purposes of the potter; but by purging the paste of the accidental ingredients, the iron, lime, &c., we exalt those properties which render it fit for the preparation of fictile articles. An intimate mixture of silica and alumina with water acquires, by exposure to a high temperature, the required degrees of hardness and density; but for many purposes it is necessary to impart a certain degree of fusibility, to which end other substances are used in various proportions, capable of forming vitrifiable double silicates with alumina and silica. These substances, diffused through the paste formed by the simple silicate of alumina, in some cases with silica in excess, in others with excess of alumina, greatly contribute to the cohesion and hardness of the mass. The various mixtures employed in the different branches of the manufacture, have been thus classified by M. Dumas:—

Silica, alumina	Ideal type
Silica, alumina, lime	Earthenwares, crucibles, bricks, tiles, encaustic tiles, and common pottery
Silica, alumina, oxide of iron	
Silica, alumina, lime, oxide of iron	
Silica, alumina, potash	Hard porcelain
Silica, alumina, soda	Soft porcelain
Silica, alumina magnesia	Piedmont porcelain
Silica, alumina, baryta	Stoneware.

(6561) PRABANATHA. SEEDS OF CASSIA TORA: *Ben. Phar.*

(6562) PRANGOS, a genus of Plants of the natural family of *Umbelliferæ*, tribe *Smyrneæ*, so named by Dr. Lindley from the name by which the only species is known in its Tartarian habitat, where it was discovered by Mr. Moorcroft, in the neighbourhood of Imbal or Droz, and which he visited for the purpose of examining into the reputed qualities of this plant, of which the accounts seemed to border on exaggeration. Almost all the knowledge which we possess respecting the plant, is derived from the observations of that lamented and enterprising traveller. The Prangos Hay-Plant is herbaceous and perennial, having a large fleshy root stalk, usually measuring at the top from 18 to 22 inches in circumference, and formed by the aggregation of an infinite number of crowns or winter-buds, clustered together at or above the surface of the ground. These crowns being closely covered by the fibrous remains of the old leaves, are thus protected from the frosts of winter. The crop consists of the leaves, which rise in abundance from each crown, are finely cut, about two feet in length, and have a highly fragrant smell, extremely similar to that of very good new clover hay. This Mr. Moorcroft considered as a most important and interesting object of rural economy, and says that the properties of Prangos as a food appear to be heating, producing fatness in a space of time singularly short; it is also destructive to the *Fasciola hepatica*, or Liver-Fluke, which in Britain, after a wet autumn, destroys some thousands of sheep by the rot. The last mentioned property, of itself, if it be retained by the plant in Britain, would render it especially valuable to that country. But this, taken along with its highly nutritious qualities, its vast yield, its easy culture, its great duration, its capability of flourishing on land of the most inferior quality and wholly inadapted to tillage, impart to it a general character of probable utility unrivalled in the history of agricultural productions. When once in possession of the ground, for which the preparation is easy, it requires no subsequent ploughing, weeding, manuring, or other operation, save that of cutting and of converting the foliage into hay. Of its duration he relates that its seeds, having been carried westward along with those of yellow lucerne, above 40 years ago, and sown on the eastern frontier of Cashmere, vegetated, and that the plants of the first growth still remain in a flourishing condition. He conceived that by the cultivation of this plant, moors and wastes hitherto uncultivated may be made to produce large quantities of winter fodder, and that the yield of high lands and downs enjoying a considerable depth of soil may be trebled. Dr. Falconer, in his visit to Cashmere and Tibet, found it in the latter, as well as on a low trap hill in the former, but not so vigorous in the Cashmerian as in its Tibetan habitat. He states that though abundant in various directions, the Cashmerians do not esteem it of any value. Arrian, in describing Alexander's expedition across the mountains which he calls Caucasus and Paropamisus (iii. 28), says, nothing but *Silphium* and the Turpentine-Tree grow there, notwithstanding which it is very populous, and multitudes of sheep and neat cattle are seen, for they feed upon *Silphium*, of which the sheep especially are very fond. This bears so close a resemblance to the *Prangos*, both in locality and properties, that it is as likely to have been the *Silphium* of the ancients, as the assafœtida plant,

which it is supposed to be by others.—*Eng. Cyc.*

(6563) PRANGOSI PABULARIA. Vern. Fiturasulioon, north of India, near Dnz. This plant constitutes excellent fodder for cattle, fattens quickly, and destroys the "liver fluke" of sheep. Mr. Royle considers this one of the plants which yielded the Silphium of Alexander's historians.—*O'Shaughnessy page* 369. The celebrated Prangos Hay plant Grass was discovered by Mr. Moorcroft, in Tibet, and found by him to be employed as winter fodder for sheep and goats, and frequently for neat cattle. Mr. M, writing from the neighbourhood of Droz, describes the Prangos Hay plant as producing fatness in a space of time singularly short, and likewise as being destructive to the River Fluke; he therefore justly concluded that it would be an invaluable acquistion to any country to the climate of which it was suited, as its highly nutritious qualities, its vast yield, its easy culture its great duration, its capability of flourishing on lands of the most inferior quality and wholly unadapted to tillage, impart to it a general character of probable utility unrivalled in the history of agricultural productions. When once in the possession of the ground, for which the preparation is easy, it requires no subsequent ploughing, weeding manuring, or other operation, save that of cutting and of converting the foliage into hay."—(*Moorcroft* in a letter to W. Butterworth Bayley, Esq, formerly Chairman of the Court of Directors.) Various attempts have been made to introduce the Prangos Hay plant into Great Britain, but hitherto unsuccessfully; and it is probable it will only succeed, and be valuable in a climate similar to that where it is found indigenous. The Prangos is highly valued in the cold and arid region of Tibet, where it is indigenous, and which Mr. Moorcroft (v. p. 179) thought would be valuable as fodder for sheep and cattle in European countries. It is found in Tibet, and also most abundantly on Ahatoong, a low trap hill in the valley of Cashmere; but there it was not so vigorous as in its Tibetan habitat. Though abundant in various directions, the Cashmerians do not esteem it of any value, and Dr. Falconer is of opinion that its importance has been much over-estimated, in consequence of its being the only food in many of the bleak and barren tracts of Tibet. In Cashmere, where far from a deficiency of herbage there is actually a superabundance of pasture grasses, it is necessarily much less esteemed. The Prangos will, therefore, most probably be a valuable acquisition only in countries devoid of good natural pasturage and of which the climate is favourable to its growth.—*Royle, Pro. Res.*

(6564) PRAWN.

Eeral, Tam.	Roielleo Tel.

Ains. Mat. Med. p 155.

(6565) PREMNA, a genus of Plants of the natural family of *Verbenaceæ*, which is characterised by a cup-shaped calyx, a 5-cleft bilabiate corolla. Stamens 4, didynamous. Drupe pea-shaped, with a 4-celled nut. The species consist of shrubs and small trees, which are indigenous in Asia and Australia, having opposite leaves, inflorescence in terminal cymes, with small flowers. The majority of the species are remarkable for the fetid odour of their leaves; though those of *P. cordifolia* are somewhat fragrant, and those of *P. esculenta* are employed as diet by the natives of Chittagong. *P. integrifolia* has roots of a burning taste, with leaves of a hircine odour. The leaves, applied to the head, are said to cure headache, and a decoction of the roots is employed as a stimulant in fevers, flatulence, &c. *P. latifolia* has wood of a white colour and firm texture, employed for various economical purposes, in which it agrees in character with the teak trees. *Gmelina arborea*, and others which belong to the same natural family. —*Eng. Cyclopædia.* Of this genus, Dr. Wight, in Icones, gives *Cordifolia*, 1483; glaberrima, 1484; integrifolia, 1469; latifolia, 869; serratifolia, 1469; thyrsoidea, 1485; tomentosa, 1468; Wightiana, 1485.

(6568) PREMNA SERRATIFOLIA.

Munnæ keeray, Tam.

Leaves used similar to those of P. Integrifolia. The natives are very fond of these two species.—*Jaffrey.*

(6569) PREMNA TOMENTOSA, Verbenaceæ, Icon. 1468.

Kolcuttay teak marum, Tam.

A small tree, the wood hard and close grained, of a brownish yellow colour, well fitted for ornamental purposes.—*Wight.* It is a native of the mountainous parts of the Circars.—*Rohde.*

(6570) PRESENTS IN JAPAN. There are three articles which, in Japan, always form part of an Imperial present. These are rice, dried fish and dogs. Some also said that charcoal was always included. Why these should have been selected, or what they particularly symbolize, was not learned.—*American Expedition to Japan. p.* 429.

(6571) PRESERVED PROVISIONS. supply of fresh meat and vegetables is essential not only to the comfort but even the health. Until recently this object could only be obtained in the navy by taking on board a large quantity of live stock, the maintenance of which at sea for weeks and months was not only very expensive but the supply thus procured was constantly lamentably short of the demand. The result of this deficiency of fresh provisions frequently displayed itself in the prevalence of scurvy and other disorders, now happily nearly eradicated, but which have been computed to have slain more seamen than ever fell in action. But by the art of preserving supplies, when the earth is covered with snow and when vegetation seems extinct—locked up as it were in the icy grasp of death.—our tables may be loaded with the choicest vegetable productions of the spring of the summer and of the autumn. When the salmon, the turbot, the mackerel, the lobster and other dainties of the ocean have become unfit for food or have left our rivers and our shores, a sufficient supply would remain ready for use in the canisters in which they are cooked, and which will preserve them for us in full flavour The free denizens of the air and of the forest will be also at our command at all seasons and at periods when the sportsman could not reach them or when otherwise they would be unfit for our consumption. Both the animal and vegetable kingdom would thus be at our command in all periods and seasons to administer to the wants and cap-
the-s of the stomach and to render our kitchens
tat- alone independent of the winds and of the
in th-s and of the mutations of the seasons but

tions of t- moment's notice those articles of diet

PRESERVED PROVISIONS.

either best suited to his disorder or such as alone are acceptable to his capricious appetite. The process proposed by Mr. Forsyth appears recently to have been put into execution with very considerable success under the patent of M. Masson, Head Gardener to the Horticultural Society of Paris. The gentleman has succeeded in preserving in a very perfect manner various descriptions of vegetables and fruits, the substances thus preserved are dry and shrivelled, contain but little water, and it is evident from their appearance that a very essential part of the process of preservation consists in the abstraction of the water which forms so very considerable a portion of the weight and bulk of nearly all vegetables and fruits. When vegetables thus prepared are immersed in water for some time they swell up become soft and tender and resume to a very great extent the appearance, colour and flavour proper to them in the fresh state. M. Masson has managed to preserve completely spinach, Brussels sprouts, cabbage, beans, peas, sliced carrots, parsnips, potatoes, apples, &c. Having ourselves submitted samples of each of these fruits and vegetables to examination we are in a position to speak from personal knowledge and observation and are enabled to state that the results obtained apparently in so simple a manner are really surprising. In the ordinary mode, the article to be preserved is placed sometimes in the raw state but generally cooked in a tin canister, the lid of which is soldered down but is perforated with a small aperture or pin hole. It is then subjected to the action of either steam, boiling water, or a muriate of lime bath, until the contents of the canister, if not previously dressed, have become about two-thirds cooked. The aperture in the cover is then closed, and the canister and its contents are once more submitted for a shorter period,—that is until the article is completely dressed to the operation of heat. As soon as it has become cold the canister is covered over with a coating of paint; its preparation is then complete, and it is removed to the proving room. The proving room is simply an apartment the temperature of which has been raised to the degree most favourable to decomposition. If the operation of preservation has been well performed, the top and bottom of the canister, as also, in some cases, the sides, will have fallen in, or have collapsed to some extent: this indicates the exhaustion of the air within, and is regarded by the manufacturer as a tolerably correct proof that the process has been properly conducted. If, however, after some days' exposure in the proving room, the top and bottom of the canister first become flat, and subsequently even convex, it is a certain sign, that the contents have not been well cured, and that they are not in a condition to keep for any length of time. Such canisters

have therefore to be either rejected, or else subjected to the same process over again. It should be known that it is not only boiled provisions which may be preserved by the above process, but roasted also, with but a little extra care. The chief articles employed for the preservation of organised substances, are salt, sugar, oil, charcoal, acetic acid, or pyroligneous acid, and alcohol salt is used in the curing of fish of different kinds, bacon, hams &c., in the pickling of pork, and in the corning of beef. Salt possesses great affinity for water which it abstracts largely from the substance to which it is applied and to which affinity its power as a preservative agent is mainly due. Its effect in abstracting water from meat is well seen, in the pickling of pork, in the large amount of fluid termed brine which escapes from the meat. Unfortunately the effect of salt in its application to the preservation of meat is not confined to the removal of water; it hardens the fibre so as to render it tough and indigestible; and at the same time the water, the discharge of which it occasions dissolves out of the meat several of its most important constituents, as the albumen, Kreatine, Kreatinine, lactic acid, and soluble phosphates. Again this salted meat, by the subsequent boiling to which it is subjected, has its nutritive properties still farther impaired, for this extracts much of the gelatine and osmazome, thus at length little else of the meat is left besides the fibre which is so insoluble and comparatively destitute of nourishment. Salt exerts the same effect on vegetable substances as on animal: this is seen in its application to sliced cucumbers and other vegetable. Salt and water, termed "brine," is largely employed by pickle-makers for keeping a reserved stock ready for use, at all times and in all seasons, of the different kinds of vegetables used by them for pickling. The larger makers have some hundreds of hogsheads filled with various vegetables, in some beans, in others, gerkins, &c., thus preserved in salt and water. We have been given to understand that they keep well for months in this way. The salt and water is selected in preference to vinegar on the score of economy. Sugar is principally employed for preserving fruits, either entire or in the state of Jam or marmalade. In the condition of syrup it is semi solid, and operates partly by the barrier which it interposes to the free access of the atmosphere to the surface of the fruit, and partly in consequence of its being a non nitrogenous substance.

The use of oil as a preservative medium is extremely limited; sardines and anchovies are nearly the only articles commonly put up in oil. It appears to operate in the same manner as sugar. The powerful effect of charcoal retarding putrescence in meat and even in restoring tainted meat to a state of sweetness, is well known. Its action is due to its property of absorbing gases and effecting their oxydation as rapidly as they are developed from the decomposing meat and which is made to preserve at least the appearance of freshness. The use of dilute acetic acid or vinegar is confined to the preservation of vegetable substances, and is employed principally by pickle makers. We are not aware that its mode of operation is well understood, it probably acts chiefly by the coagulation of the vegetable albumen which it occasions Pyroligneous acid, which is an impure kind of acetic acid, possessing a smoky flavour, is applied in two ways to the preservation and curing of such articles as hams and red herrings, either in the fluid state on in that of vapour; in the latter case it proceeds from the wood or turf employed in the drying, and which being continually formed and evolved during the imperfect combustion of the wood or turf gradually penetrates into every part of the meat, imparting the flavour which is so much esteemed. Its action is no doubt the same as that of acetic acid. Alcohol is but little used in the preservation of alimentary substances, although some fruits, as cherries, are often preserved in brandy. For the preservation of anatomical preparations it is the best liquid known. Its action is in part due to its affinity for water.

(657.) *Pemmican* Pemmican consists of the muscular fibre of beef baked and reduced to a coarse powder. The preparation of the article has been described to us as follows.—The beef trimmed and deprived as far as possible of fat is cut into slices, which are placed on metallic plates, and baked until it becomes dry, hard, and cooked, lastly, the slices are reduced to a coarse and fibrous powder. The articles in this state constitutes what is known as common pemmican. There are, however, other preparations of pemmican: thus a proportion of fatty matter is commonly added with the intention of restoring the fat, of which the meat was necessarily deprived, in order that it might be baked and thus rendering it the better adapted to serve all the purposes of nutrition and respiration. Again, to this mixture of muscular fibre and fat, in some cases sugar is added, and in others, currants. Pemmican is prepared at Gosport in large quantities for the use of the navy, and we believe, is considered to form a valuable and nutritive article of diet. We have been informed that the North Star, which proceeded in search of Sir John Franklin, had a large supply on board. It is used, particularly that with sugar, mixed with the cocoa given for breakfast, and the other kinds with gruel, broth, or soup. Further information in regard to the preparation and use of pemmican will be found we believe, in "Sir John Richardson's Arctic Boat Voyage." Of all the processes used for the preservation of vegetable substances,

there appears to be none so satisfactory as that of M. Masson. That fruits preserved in bottles according to the method of Mr. Sadlington lose very considerably in flavour, is unquestionable, yet the process on the whole, yields valuable results. We believe that the most effectual means of preserving fruit is by immersion in syrup; the expence of this, however, is too great to allow of its use in all cases.—*Food and its adulteration, p.* 428.

(6573) PRESERVES, &c. The Chinese candy many things which are not considered fit for such purposes elsewhere, as millet seeds, bamboo shoots, slices of the lily root, &c., these are hawked about the streets. Ginger root, preserved in sugar, is the most common sweetmeat exported; it is made of the tender roots of the ginger plant (*Zingiber officinalis*), and when good has a bright appearance, a dark red color, and is somewhat translucent. If the roots are old, the conserve will be stringy, tough and tasteless. Much of this kind of sweetmeat is carried to India for consumption there, and for re-exportation to England and the Continent; the export to the United States is considerable; also to Sydney, South America, &c. Other kinds of conserves, as wampee, guava and pear, jelly, citron, kumquat, oranges &c &c., are also sent abroad; the total exportation may be put down at 10,000 boxes, value about $ 50,000. A box is estimated at 25 catties.

(6574) PRICKLY PEAR, *Opuntia Dillenii*, Cactus Indicus. The hedge prickly pear is often seen in gardens, and its large yellow flowers are quite ornamental. The natives of Tenasserim regard it as a species of euphorbia. —*Mason.*

(6575) PRIMULA. The Primrose. This family of plants includes the Auricula, Polyanthus, and the Primrose. They all form in Europe ornamental border flowers; but will not succeed in S. India.—*Riddell.* Wight gives Primula denticulata, 2000.

(6576) PRINCE'S FEATHER, Celosia. This is the most elegant plant, when cultivated by the Karens, that I ever saw of the amaranth tribe. It is not the prince's feather of English writers *Amarantus hypochondriacus*, but a species of Celosia which bears a long pendulous drooping panicle or plume like Roxburgh's *C. cernua*, but it is a different species. There are two varieties, one with bright yellow flowers, the other with red.—*Mason.*

(6577) PRINIA (Horsfield), a genus of Birds. It has the following generic character:—Bill rather lengthened, much compressed, entire; rictus smooth, wings rounded, tail broad and cuneate; feet large, strong.—*Swainson.*

(6578) PRINIA FAMILIARIS may be taken as an example. It is the Prinya of the Javanese, Familiar Creeper of Latham. It is abundant in many parts of Java, near villages and gardens, in the confines of which, among trees and shrubs, it builds its nest. It is a sprightly bird, sporting among the branches in short and rapid flights, and has received its native name from its lively and pleasant notes.—*Horsfield.*

(6579) PRINSEPIA, a genus of plants of the natural family of *Chrysobalanaceæ*, so named by Dr. Royle in honour of James Prinsep, Secretary of the Asiatic Society of Calcutta. The genus consists of only a single species, remarkable for its thorny appearance, but it may be considered typical of the labours of the individual whom it is designed to commemorate, as, early in the season, it is conspicuous for the abundance of its inflorescence, and, later, for that of the purple-coloured berries with which it is loaded. The seeds are large, and yield by expression an oil which is highly esteemed by the mountaineers of the Himalayas, where it is indigenous, and which by Europeans is thought a good substitute for salad oil.—*Eng. Cyc.*

(6580) PRINSEPIA UTILIS, is a common north-west Himlayan plant, only found at 8 00 feet in Sikkim: it is employed in hedges—*Hooker, Him. Jour. Vol.* II. *page* 291.

(6581) PRIONODON, Dr. Horsfield's name for a feline form (*Felis gracilis*, Delundung of the Javanese), and placed by him in a separate section under the name of *Prionodontidæ*, between *Felis* and *Viverra*. ('Zoological Researches in Java.') Mr. Swainson remarks ('Classification of Quadrupeds'), that of the genus *Prionodon*, at present, but one species has been found in Java. As a familiar appellation, expressive, in all probability, of its analogy to the *Soricidæ*, he terms it the Shrew Cat.

$$\text{Incisors, } \frac{6}{6}; \text{ Canines, } \frac{1\ 1}{1\ 1}; \text{ Molars, } \frac{5\ 5}{6\ 6} = 38.$$

(6582) PRIONODON GRACILIS, has the tail elongated, annulated, cylindrical; body pale flavescent, with four very wide dorsal bands and two narrow anal bands; two broad lateral striæ, the narrow cervical striæ, the numerous humeral and femoral spots, and the seven caudal rings very deep brown.—*Horsfield.*

Dr. Horsfield discovered this animal in 1806, during the early period of his researches in the district of Blambangan, situated at the extremity of Java; the natives distinguish it by the name above given. Dr. Horsfield was not able to ascertain that it is found in any other part of the island, or that it has another name; but he states that even in Blambangan it is rarely met with. He notices it as inhabiting the extensive forests which, with the exception of the capital of Banyuwangi and a few small villages, cover that district. He obtained but little information as to its habits and manners, and records nothing on the subject beyond what we have mentioned.—*Eng. Cyc.*

(6583) PROCELLARIDÆ, a family of Oceanic Birds belonging to the order *Natatores*.

They are well known to the seamen when far from land, and with which his superstition was once more busy than it is now; but even at the present day they are not unfrequently regarded as ominous, and many a hard-a-weather old quarter-master still looks upon 'Mother Carey's Chickens' as the harbingers of a storm. Though zoologists have differed as to the genera to be included in this extraordinary group, they have been pretty well agreed as to the forms which should be congregated in it. The genus *Procellaria* of Linnæus was formed by that great zoologist for the Petrels, and it is closely followed by his genus *Diomedea* (Albatrosses), between which and the Petrels there are many points of resemblance both in their structure and their pelagic habits. [DROMEDEINÆ; LARIDÆ.] Prince Bonaparte ('Geographical and Comparative List,' 1838) makes the *Procellaridæ* the thirty-fourth family of the birds, and places them between the *Laridæ* and the *Colymbidæ*. It includes the genera *Diomedea*, *Procellaria*, *Puffinus*, and *Thalassidroma*. Mr. G. R Gray ('List of the Genera of Birds,' 1854) makes the *Diomedeinæ* the first sub-family of the *Laridæ*. This sub-family comprehends the genera *Pelecanoides*, *Puffinus*, *Daption*, *Thalassidroma*, *Wagellus Procellaria*, *Diomedea*, and *Prion*. M. Temminck, in his 'Manual' (2nd part, 1820), arranges all the Petrels under the generic name *Procellaria*, Linn., but divides them into the following sections:—

1. Petrels properly so-called, *P. glacialis*.
2. *P. Puffinus*, *P. Anglorum*, and *P. obscura*.
3. Swallow-like Petrels (Petrels Hirondelles), *P. Pelagica*, and *P. Leachii*.

(6584) *Daption.*—*D. Capensis*, Stephens; *Procellaria Capensis*, Linn.; Cape Pigeon of the English; Peintada of the Portuguese, may be taken as an example of this form. Its plumage is variegated with brown and white. The total length of one measured by M. Lesson was 13 inches, that of the tube of the nostrils 6 lines. The testicles were rather deep-gray, the larynx had two muscles proper to it, and the total length of the intestinal tube was 47 inches. M. Garnot communicated to M. Lesson a species which the latter believed to be new, with an elaborate description and anatomical details, which M. Lesson quotes at length.

(6585) *Prion.* The type of this genus is the Blue Petrel (*procellaria vittata* and *P. cærulea*, Gmelin) discovered by Forster. Many individuals were taken during the voyage of the 'Coquille,' in 58° S. lat. The following is from M. Garnot's description of an individual of this species, which, in the form of its bill at least, appears to be leading the way towards the Lamellibranchiate Palmipedes. It is distinguished from the other Petrels by the disposition of its bill. The mandibles are hooked at their extremity; their base is very much widened. The edges of the upper mandible are directed a little outwards; they present within a projecting border striated transversely; the interval which separates them exhibits a small groove. The tongue is very thick and the mouth very dilatable. Total length, from the bill to the extremity of the tail, 11 inches (French). Length of the nasal tube 3 lines. Extent of wings 20 inches. Size a third larger than *Thalassidroma pelagica*; upper part of the body ashy-blue or gray-blue, deepest on the head and on the wings. A blackish band cuts across the wings and the lower part of the back near the origin of the tail. This portion is deepest in colour; the extremity of the tail has the same blackish deep-blue tint; lower part of the body and wings white; above the tail a line of a blue tint; bill and eyes plumbeous blue; middle of the upper mandible and tube of the nostrils blackish. The middle tail-feathers are rather the longest, which gives the tail a rounded appearance. The same author gives an interesting detail of the anatomy of the bird. —*Eng. Cyc.*

(6586) PROSOPIS SPICIGERA.

Vanjimaram Pallua, TAM. | Tshamie pundoo, TEL.

Parumbay marum, *Tam.* A thorny tree, not uncommon in the black cotton soils, attaining a large size in Mysore. Wood strong, hard, straight grained, and easily worked. The foliage of the tree and the character of the wood, closely resembles that of its congener *Acacia sundra*. Wight No 84. This tree attains a considerable size and the timber is strong and hard, used for bandy wheels and other common purposes. A specimen of this wood supported 592 lbs. Is it the same as the vunny marum? The botanical specimens which accompany both belonged to Prosopis spicigera. The specimens brought to Dr. Wight under this name were not in flower, but seem quite identical with those of the purrembay; this therefore is, he believes, the Tamool, the other the Mallayalum name. The wood, if I have not mistaken the species, is very strong, sustaining nearly 600 lbs; is hard, straight-grained and easily worked, but it may be another name for curreugaly, the foliage of which is very like that of Prosopis spicigera.—*Wight.* This pod is about an inch in circumference and from six to twelve long. When ripe it contains a quantity of a mealy substance which has a sweetish taste, and is eaten by the natives.—*Ainslie, p.* 3 4.

(6587) PROSOPIS SPICIGERA? MIMOSEÆ, Roxb. c. 63.

Punambay wood, ENG. | Parumbia marum or Vunny marum. TAM.

(6588) PROTEA. PROTEACEÆ. These plants are natives of the Cape, and would be found difficult to cultivate from their fleshy roots; the soil best suited for their growth is light loam mixed with sand, they require great attention as

they suffer either from a want or excess of water. —*Riddell.*

(6589) PROTIUM CAUDATUM. TEREBINTHACEÆ.

Malay Kloovy, TAM.

A moderate sized tree; the wood as shown by the branches is very brittle and full of sap, apparently of no value.—*Wight.*

(6590) PRUNELLAS.

Aloo Bokhara, GUZ. HIND. PERS.

Have a reddish-yellow colour, and a sweet grateful taste, with a slight and pleasant acidity. They are a variety of prunes, and are brought to Bombay from the Persian Gulf.—*Faulkner.*

(6591) PRUNES.

Aloo Bokhara, GUZ HIND. PERS.

A species of dried plum, of which there are many varieties. They are generally of an oblong shape, and sweet taste, and are prepared in France, Germany, Portugal, and other parts of the Continent. Those procurable in Bombay, are brought from the Persian Gulf.—*Eng. Cyc.*

(6592) PRUNUS, a genus of Arborescent Rosaceous Plants, belongs to the Amygdalous division of the order, and comprehends several of our domestic fruits. The Cherry, Bird-Cherry, Plum, Damson, Sloe, Bullace, and Apricot, are all comprehended in the genus as limited by Linnæus; but in the opinion of some modern botanists, the true Plums require to be separated from the others, and should exclusively constitute the genus *Prunus*, while the others are to be considered as belonging to two other genera, represented by the Cherry and the Apricot. In this view of the subject, each genus is characterised thus:—

(6593) *Armeniaca*, the Apricot.—Drupe woolly outside. Stone blunt at one end, sharp pointed at the other, with a furrow passing all round it, and an even surface. Young leaves rolled up.

(6594) *Cerasus*, the Cherry.—Drupe smooth, without bloom. Stones roundish, smooth. Young leaves folded flat.

(6595) *Prunus*, the Plum. Drupe smooth, covered with bloom. Stone sharp-pointed at each end, furrowed all round, and smooth on the surface. Young leaves rolled up. Of the Plum genus, thus restricted, there is in common use the Garden Plum (*P. domestica*), with all its numerous varieties, the Bullace (*P. insititia*), and the Sloe (*P. spinosa*). These plants are distinguished specifically by botanists, but apparently without reason. It is the opinion of the best experimental physiologists, that the Sloe of our hedges was the origin of the others; and certainly there is not more difference between a Sloe and a Greengage than there is between a German Quetsche and an English White Magnum-Bonum. Several other species belong to the genus, but they are of no moment, with the exception of a plant called *Prunus coccomilia*, which inhabits the mountains of Calabria, and has a great reputation in Italy on account of the tonic qualities of its bark.—*Eng. Cyc.*

(6596) PRUNUS ARMENIACA. AMYGDALINEÆ.

Zard alu, HIND.

The Apricot. This tree grows to a large size in gardens of the Deccan. It blossoms at the same season as the peach, from January to March; the fruit forms and attains the size of a common marble, after which it falls off, and this no care can prevent. Many efforts have been made to get buds to take both on the peach and almond stocks but without success, attempts to graft it by approach have hitherto been unsuccessful: the tree grows well on the first range of the Himalayas, bearing abundance of fruit in the months of May and June. Propagated in the same way as the peach.—*Riddell.*

(6597) PRUNUS CERASUS.

Padam, HIND

The Cherry. This tree is not found in any part of the Deccan; but abounds wild in the hills north of Deyrah Dhoon, producing a small common black fruit fit only for preserves, &c.—*Riddell.*

(6598) PRUSSIAN BLUE, BLUE PRUSSIATE OF IRON, FERRI FERROCYANIS, FERRO-PRUSSIATE OF IRON, PERCYANIDE OF IRON, SESQUIFERROCYANIDE OF IRON.

Bleude Prusse, FR.	Lasor Bexlinskaja, RUS.
Berlinerblau, GER.	Azul de Prussia, SP.
Azurro Prussiano, IT.	

A pigment or dye, composed of cyanogen and iron, and procured by a chemical process from carbonate of Potass, bullock's blood, green vitriol, and alum. It is prepared of different degrees of purity, and additions are made to it according to the purposes for which it is required. When pure, it is of a rich and intense blue, with a copper tint on the surface, inodorous, tasteless, insoluble in water, in alcohol and diluted acids; but is acted upon and dissolved by strong acids. Prussian blue is now extensively made in China, the art of manufacturing it having been carried from the West to the East by a Chinese sailor. —*Waterston*—*Faulkner.*

(6599) PRUSSIC ACID. HYDROCYANIC ACID. Is obtained by the action of muriatic acid on bi-cyanuret of mercury. It is limpid, very volatile, and of a strong pungent odour, resembling that of bitter almonds. Its taste is acrid, and it is virulently poisonous. In medicine it is used as a sedative.—*Waterston.*—*Faulkner.*

(6600) PSIDIUM, (from ψίδιον) the Greek name for a pomegranate), a genus of Plants belonging to the natural order *Myrtaceæ*. The tube of the calyx is ellipsoid or obovate, usually contracted at the apex; the limb ovate, undivid-

ed, but afterwards from 1- to 5-cleft. There are five petals and numerous free stamens inserted in a broad circle, almost through the whole undivided part of the limb; the style is filiform, the stigma capitate; the ovules are numerous, horizontal, and fixed to the margin of the placenta; the berry is many-seeded, corticate by the tube of the calyx, and crowned by its lobes. The seeds imbedded in the pulp in the mature fruit with a bony testa. The species are trees or shrubs, natives of America within the tropics The fruit is edible, and is known by the name of Guava. It has a fragrant but peculiar odour and very sapid taste, and is eaten both raw and when made into jelly.—*Eng. Cyc*

(6601) PSIDIUM POMIFERUM, Apple-Bearing or Common Red Guava, has tetragonal branches, oval or oblong lanceolate leaves, pubescent beneath, from 3 to 8 peduncles, or many-flowered. The fruit is globose, yellow, and somewhat astringent, with an agreeable odour; the root and young are astringent; and are esteemed strengthening to the stomach. It is a native of the West Indies, Mexico, and South America.—*Eng. Cyc.*

(6602) PSIDIUM PYRIFERUM. WHITE GUAVA.

Soopari am or Soopium HIND.	Peyara, BENG. Jam, DUK.

The Wood.

Guava wood, ENG.	Jama kurra, TEL.
Conya marum, TAM.	Sebe mara, CAN.

The guava tree is planted in Tenasserim perhaps more extensively than any other fruit tree in the country. Loudon has the most correct notion of the fruit. He says: "Most of the species are cultivated in the tropics for their fruit, which also ripens freely in this country, but is of little merit." The white guava is the species most usually cultivated but the red is not uncommon—*Mason*. Besides yielding fruit, the wood is useful for many purposes as handles of tools, mallets, pegs, &c., it is very hard.—*Rhode. M S.S*

The Fruit.

Coia pallum, TAM.	Pera coy, MAL
Jamb, DUK.	Guava, ENG.
Goia pundoo TEL.	Nichola, SANS.

This Indian fruit is generally preferred fresh from the tree in the morning early; as the heat of the day is supposed to injure its flavor. —*Ainslie, p.* 223. It grows in all parts of the Deccan. The fruit is both red and white, pear shaped and round: it is esteemed as a dessert fruit, but the scent when too ripe is unpleasantly powerful; it makes a most excellent jelly, and also is prepared in a similar manner to damson cheese at home. The fruit sometimes is as large as a common baking pear, and one weighed half a pound. They have been brought to great perfection in some gardens, and the fruit of a large size divested almost of seed: this sort generally has a very rough knotty coat, and is more spongy and less firm than the other varieties. A plants continually grown from layers in time cease to produce seed, perhaps this variety has been so procured. It is easily increased by seed, and only requires a good soil to thrive in. The trees should be pruned once a year, otherwise the branches become very straggling. Good gun-stocks are made from the old wood.—*Riddell.* In all Southern Asia the common Guava is found every where in gardens, which probably found its way to India from S. America through the Portuguese, Wood small, but very hard, and is used by Dr. Hunter for wood engraving, and commonly for pegs, mallets, handles of too's, &c.—*M E. J R.*

(6603) PSITTACIDÆ, an extensive and highly-interesting family of Birds, including those commonly called Parrots. They are remarkable for their beautiful colours, their powerful bill, their fleshy tongue, and their power of imitating the human voice. The articulation of some of the species is so perfect, that when the bird is unseen it is difficult to suppose that the words pronounced do not proceed from the mouth of man

Mr. Swainson is of opinion that the Parrots constitute the subtypical division of the *Scansores* wherein the powers of climbing are less developed. "If," says Mr. Swainson, "any group in nature be isolated, it is this. Possessing in themselves the strongest characteristics, there is no bird yet discovered which presents any point of connection to them: approximations indeed are certainly made towards them by the tooth-billed Barbuts (Barbets, *Pogonias*); but there is still a gap, which no genus yet discovered is calculated to fill up. On considering the relative difference between the Barbuts and the Parrots, we should say, theoretically, that of all the five groups among the latter, one only remains to give the typical structure." As the Parrots appear to Mr. Swainson to form a group precisely equivalent to the true Woodpeckers, he arranges them under five genera: the Maccaws, the Parrots, the Cockatoos, the Lories, and the Ground Lories (*Platycercus*, Vig.) In the synopsis at at the end of the work ('Classifiction of Birds'), we find the following arrangement:—

Psittacidæ.

Bill every short: the upper mandible greatly curved over the lower, which is considerably shorter.

Sub-Family *Macrocercinæ*. Maccaws.

Upper mandible greatly hooked; lower mandible much higher than broad. Tail very long, cuneated.

Genera: *Macrocercus*, Vieill.; *Conurus*, Kuhl; *Leptorhynchus*, Sw.; *Palæornis*, Vig.

Sub-Family *Psittacinæ*. Parrots.

Upper mandible very distinctly toothed; lower mandible longer than it is high. Tail short, even, or rounded

Genera: *Erythrolomus*, Sw.; *Chrysótis*, Sw. (Amazonian Parrots); *Psittacus* (Parrot of the Old World—most typical of this sub-family); *Agapornis*, Selby; *Poicephalus*, Sw.

Sub-Family *Plyctolophinæ*. Cockatoos.

Head large, ornamented with a folding or procumbent crest. Bill short, very broad; the culmen remarkably curved. Tail rounded, lengthened, broad; the feathers not narrowed.

Genera: *Plyctolophus* Vieill. (subtypical); *Licmetis*, Wagl.; *Microglossus*, Geoff.; *Centrourus*, Sw.

Sub-Family *Lorianæ*. Lories.

Bill but slightly curved; the margin of the upper mandible sinuated; the notch obsolete; lower mandible slender, conic, much longer than high; the gonys (typically) straight.

Genera: *Brotogeris*, Vig.; *Psittaculus*, Kuhl; *Trichoglossus*, Vig.; *Lorius*, Brisson; *Pyrrhodes*, Sw.

Sub-Family *Platycercinæ*. Loriets.

Tail long, very broad, considerably cuneated. Bill strong, thick, toothed; the culmen very convex. Under mandible deep, but very short: the gonys curved. Feet and toes slender. Tarsus longer than the hallux.

Genera: *Vigorsia*, Sw.; *Platycercus*, Horsf. and Vig.; *Nanodes*, Horsf. and Vig.; *Leptolophus*, Sw.; *Pezoporus*, Ill. (Swainson.)

The family is placed by Mr. Swainson between the *Rhamphastidæ* and the *Picidæ*.

Mr. G. R. Gray ('List of the Genera of Birds') also arranges the *Psittacidæ* between the *Rhamphastidæ* and the *Picidæ*.

The sub-family *Palæornina*, as it appears in Mr. Vigors and Dr. Horsfield's 'Description of the Australian Birds in the Collection of the Linnæan Society' ('Linn. Trans.,' vol. xv.), consists of the genera *Nanodes*, *Platycercus*, *Pezoporus*, *Palæornis*, and *Trichoglossus*.

(6604) *Palæornis*.—The Parrakeets forming this group belong to continental India and some of the neighbouring islands in the Indian Ocean and Africa, with the exception of *Palæornis Barrabandi* (*Polytelis* of Wagler), which is a native of Australia. India and its islands must however be considered as the principal locality of the species, which, according to Wagler's monograph, amounts to eleven, including *Palæornis inornatus* which he adds to the group with doubt.

The Ring Parrakeets, as they are generally termed, are justly held in high estimation for the symmetry of their form, the grace and elegance of their movements, the beauty of their colours, their great docility and powers of imitation, and their fond attachment to those with whom they are domesticated and who treat them with kindness. They were not less prized, as we know, by the ancients; and it becomes a not uninteresting inquiry to endeavour to ascertain what were the species known to them. Some suppose that *Palæornis Alexandri* was the only one: but though that species may have been and was probably the first introduced into Europe, we think that it will appear that those who confine the Parrakeets known to the ancients to that bird have taken too narrow a view of the subject.

This genus has the following characters:—Bill rather thick; the upper mandible dilated, the culmen round, the lower mandible broad, short, and emarginate. Wings moderate; three last quills (extimis) nearly equal, longest; external webs of the second, third, and fourth gradually broader in the middle. Tail graduated: the two middle very slender feathers much exceeding the rest in length. Feet with short and weak tarsi; the claws moderate, rather slender, and falcate. Body slender and neat (Vig.)

Mr. Vigors divides the genus into the following sections:—Lower mandible short.

(6605) *P. Alexandri*, *P. torquatus*, *P. flavitorquis*, *P. bitorquatus*, *P. xanthosomus*, *P. Malaccensis*, *P. erythrocephalus*, *P. Bengalensis*, *P. Pondicerianus*, *P. Barrabandi*,

Lower mandible elongated.

(6606) *P. Papuensis*.

(6607) *Lorius*.—The true Lories are remarkable for the elongated and weak form of the bill, and also for a formation of the tongue, similar to that in *Trichoglossus*. [See, col. 476.] They are inhabitants of the islands of the east, and are considered by Mr. Vigors to be the aberrant group of the family. Their colours are of the most rich and mellow description, and the birds are highly prized, not only for their beautiful plumage, but for their lively, active, and affectionate disposition, and their great docility in the articulation of words and even sentences. The genus has the following characters:—Bill elongated, weak. Wings pointed, two first quills longest. Tail moderate, rounded or gradulated; the feathers broad, and hardly narrow at their tips.

(6608) *Lorius Domicella*.—Rich scarlet; upon the upper part of the breast a yellow collar; crown of the head blackish-purple in front, passing into violet-purple behind; upper surface of the wings green, violet-blue at the bend and margins, as are the under wing-coverts; thighs externally azure, greenish at the base; bill orange-yellow. Length between 11 and 12 inches. It is a native of the Moluccas and other Eastern islands.—*Eng. Cyc.*

(6609) PSOPHOCARPUS. In this genus the pods are oblong, and have four longitudinal wings; the seeds are roundish. It comprehends the *Dolichos tetragonolobus*, a twining annual, the pods or tuberous roots of which are a common Indian esculent.—*Eng. Cyc.*

(6610) PSOPHOCARPUS TETRAGONOLOBUS, Goa Beans. A bean commonly cultivated and used as French beans; easily known by its having 4 fringed membraneous edges,

much used by Europeans, called by the French *Chevaux de Frise*. The plant is indigenous in the Mauritius.—*Jaffrey*. In Tenasserim there is a variety of the Goa bean which produces esculent roots that are eaten like potatoes, and are a very tolerable vegetable. The young pods are also eaten like French beans.—*Mason*.

(6611) PSYCHOTRIA.

Sgau, BURM.

The genus psychotria furnishes a handsome shrub, whose small white flowers throw a delightful fragrance on the path during a morning walk.—*Mason*.

(6612) PTERIS (from πτέρον, a wing), a genus of Plants belonging to the natural order *Filices*. The thecæ arise from the points of veins placed on a nerve-like receptacle running along the edge of the leaf, forming an uninterrupted marginal sorus; the involucres are continuous with the edge of the leaf, scarious, and opening inwards.—*Eng. Cyc.* The rhizomek of *Pteris esculenta* is used as food in Australia, and that of *Marattia alata* in the Sandwich Islands.—*Simmonds*.

(6613) PTERIS AMPLEXICAULIS, STIPE-CLASPING BRAKE. A large brake is common at Tavoy with pinnate fronds, whose leaflets have two lobes at the base which clasp their stipe.—*Mason*.

(6614) PTERIS AQUILINA, Common Fern, Bracken, or Brakes, is the most abundant of the British species. It has a long tapering rhizoma, creeping, externally black. The leaves are erect, from one to six feet high, repeatedly compound with horizontally spreading divisions, whose ribs are smooth; the primary leaves are nearly opposite, the lower ones more alternate, pinnatifid segments oblong, obtuse.—*Eng. Cyc.*

(6615) PTERIS GRAMINIFOLIA, GRASS FERN. The trunks of forest trees in Tenasserim are often clothed with the green drapery of the grass fern, which grows upon them precisely like bunches of long grass. It belongs to the same genus as the common brake.—*Mason*.

(6616) PTEROCARPUS (from πτέρον, wing, and κάρπος, a fruit, in reference to the pods being girded with a broad wing), a genus of Plants belonging to the natural order *Leguminosæ*. It has a 5-cleft calyx, a corolla with 5 petals, disposed into a papilionaceous form; 10 monadelphous or diadelphous stamens, an irregular indehiscent legume, somewhat orbicular, surrounded by a wing, woody, and often rugose, in the middle 1-3-celled. The leaves are unequally pinnated. The racemes axillary, or forming terminal panicles. The species are unarmed trees or shrubs.

(6617) PTEROCARPUS. *Species*.

Ausena wood, TAM.

(6618) PTEROCARPUS. *Species*.

Jumbagum marum, TAM.

Common about Nelambore and in Wynaad; a large tree; wood used for building and fene gardens; said to be durable.—*McIvor*.

(6619) PTEROCARPUS. *Species*.

Karoo Vagoo, TAM.

A very common tree on the Western Ghauts; wood strong, durable, and much used for building.—*McIvor*.

(6620) PTEROCARPUS. *Species*.

Nou or Nagoo marum, TAM.

A very strong and durable wood, common on the lower elevations of the Neilgherries; an ordinary sized tree.—*McIvor*.

(6621) PTEROCARPUS BILOBUS. BANKS.

Vayngie wood, ENG. | Vayugie marum, TAM.

This is reckoned by the natives a very useful wood. It is of a reddish colour, and is employed in making doors and windows, and for other common purposes.—*Ains. Mat. Med. p.* 207.

(6622) PTEROCARPUS DALBERGIOIDES.

Padouk. BURM.

This is found chiefly as a large tree about the neighbourhood of Prome and inhabited places to the north of that town, but rarely in the Forests; wood red, equivalent to mahogany.—*McClelland*. It is a native of the Andaman Islands, where it grows to an immense size, and forms a valuable timber-tree, of which the wood is known as Andaman red wood, from its resemblance to mahogany; but it is redder, heavier, and coarser grained, though that of the root is finer than that of the stem. It was introduced by Col. Kyd into the Calcutta botanic garden in 1794, whence it has been spread into the country.—*Eng. Cyc.*

(6623) PTEROCARPUS DRACO. THE RESIN. DRAGON'S BLOOD.

Dumul-ook-wain. HIND.

A native of the American Islands, and especially Guadaloupe. The bark, wood, and leaves are remarkably astringent. The dragon's blood *in mass* of commerce, according to Jacquin, is the produce of this tree. Another sort, and most likely that sold in Indian Bazars, is produced by the Calamus Draco of the Straits.—*O'Shaughnessy, page* 997. The Dragon's-Blood Pterocarpus, is a tree nearly 30 feet high, with alternate shining leaflets, about 5 on each side, and an odd one, rather obtuse, entire, veined smooth, pale green below; the legumes nearly smooth. The wood of this tree is white and heavy, the bark thick and of a rusty gray colour. When first cut it presents no marks of redness, but in a little time red drops of juice begin to collect and exude from the wood. If left in the sun for about ten minutes they become hard and clear, and are collected under the name of *Sanguis Draconis*, or Dragon's-Blood. This resin formerly constituted an extensive article of commerce

from Carthagena, but from its diminished consumption its collection has ceased, and all the dragon's-blood obtained now in the market is the produce of *Calamus Draco*.—*Eng. Cyc.*

(6624) PTEROCARPUS ERINACEUS, is a tree 40 or 50 feet in height. It has unequally pinnate leaves, smooth above, downy beneath; from 11 to 15 leaflets, alternate, distant on short stalks, ovate, oblong, obtuse, or emarginate, wiry at the edge; lanceolate stipules, solitary or clustered racemes, downy from the old wood below, the young branches much shorter than the leaves. The flowers are yellow, the legumes stipulate, compressed, membranous, velvety, serrated, and undulated, prickly on the centre. When the branches are wounded, a clear bright gum exudes from them, which is one source of the gum kino of commerce, and is mentioned as such by Park. It is a very powerful remedy in obstinate chronic diarrhœas and dysenteries, and in all diseases arising from laxity of tissue. Externally it is applied as a styptic to check hæmorrhages from wounds and ulcers, and to diminish discharges.—*Eng. Cyc.* It is a moderately lofty tree. Moon, in his travels into Africa, mentions a red gum as issuing from incisions in trees, and which he mistook for Dragon's-blood. Mungo Park discovered that the tree which yielded this substance was called Pao de Sangue (Blood-tree) by the Portuguese. His specimens were determined by Mr. R. Brown to belong to *Pterocarpus erinaceus*,—a tree which has since been well figured and fully described in the Flore de Senegambie.—*Royle.*

(6625) PTEROCARPUS FLAVUS is the Yellow Sandal-Tree, and is used for dyeing yellow. Its bark is very bitter.—*Eng. Cyc.*

(6626) PTEROCARPUS INDICUS, Wall.

Padouk, Burm.

According to Mr. Mason another Kino gum tree, the Pterocarpus Indicus of Tenasserim, is a majestic ever-green, whose yellow papilionaceous flowers clustering amid the bright drooping foliage, scent the air, like the large magnolias, for several hundred yards around. It is propagated by simply planting large branches in the ground at the commencement of the rains. There are, however, two species, the red, and the white as distinguished by the Burmese - the red producing the finest timber, but the white padouk is by far the finest ornamental tree.—*Mason.* The "padouk" is a handsome tree with long waving branches and clusters of yellow flowers, which scent the air. It produces very fine timber, and may be considered one of our most valuable forest trees. This species also yields Gum Kino. Hort. Garden 55, Firth.—*M. E. J. R.*

(6627) PTEROCARPUS MARSUPIUM.

Vangay wood, or Yagesah wood, Eng.	Beebla, Hind.
Vangai marum Tam.	Yegassee kurrah, peeah saloo, Tel.
Whonay. Can.	Peet Shala, Hind.
Vengay, Tam.	Benba, Bia, Beebla, Duk.
Yegis, Tel.	Yegah, Beng.
Pedong Burm.	
Dhin daga, Can.	

Pterocarpus Marsupium, is a tree with a very high trunk, scarcely ever found straight. The bark has a brown outer coat which is thin and spongy, and falls off in flakes, disclosing the inner bark, which is fibrous, red, and astringent. The branches are numerous, horizontal, and spreading. The leaves sub-bifarious, alternate, pinnate, with an odd one, 8 or 9 inches long. The panicles are terminal and very large, ramifications bifarious. The flowers are very numerous, white, and with a small spot of yellow in the centre. The bracts small, caducous solitary below each division and sub-division of the panicle. The seed is solitary and kidney-shaped. This tree is thought by Roxburgh to be the one yielding Gum Kino, a well known astringent, the juice hardening into a dark red and very brittle gum-resin, which, on being powdered, changes to a light brown, not unlike Peruvian bark. Its taste is strong, but simply astringent. The real kino-tree however appears to be the P. Erinaceus.—*Eng. Cyc.* It is common all round the foot of the Ghauts, wood much used in building but exudes a yellow dye, which discolours the chunam where it comes in contact with it.—*Mc. Ivor.*

The *Pterocarpus marsupium* is one of the most lofty and striking trees in the Indian forests —it is well described by Roxburgh, in the *Flora Indica*, Vol. iii. p. 234—and figured in his *Coromandel Plants*, ii. *t.* 116. It is a very large tree, affording excellent shade and timber, the latter is of a dark brown color, and dyes yellow; for building purposes it is almost as good as teak, but cannot be used for lintels of doors, windows, &c. as it discolors the whitewash. It grows luxuriantly on the eastern ghauts, on the hills between Vellore and Salem, and on the Malabar and Canara ghauts, where large quantities of the resinous substance it yields are collected, and sent to England under the name of "kino." The tree abounds not only near Tellicherry, but along the whole Malabar Coast. Dr. Cleghorn has seen it both in the ascent of the Eastern and Western Ghauts. Dr. Wight sent to him specimens from Coimbatore, and Roxburgh found it in the N. Circars. Buchanan Hamilton mentions it under the name of *Vijaya* as occurring in Nepal and also to the eastward of Bengal. The vernacular names are as follows: Beuba, Bia, Beebla, *Duk.*; Whonay, *Can.*; Yegy, Vayga, *Beng.* It has been observed in the Concans, (*Graham.*) Rajpeepla jungles, (*Dr. Lush.*) Assam, (*Voigt.*) It yields from incisions a large quantity of blood-red juice, which on being simply exposed to the sun, hardens and then quickly cracks into little

angular masses, and crumbling fragments which constitute, without further preparation, the kino of the shops. Specimens of the exudation sent by Dr. Cleghorn to Professor Christison in 1846 from Mysore, were considered by him "quite identical with the kino of commerce." The tree being thus widely diffused, and the exudation procurable in *large quantity*, it may possibly come into extensive use in *dyeing* and *calico-printing*. The product can be obtained with facility by simply incising the bark and requires no outlay save that of collecting.—*Cleghorn*. Mr. Melvor says, it is common all round the foot of the Ghauts, wood much used in building but exudes a yellow dye which discolors the chunam where it comes in contact with it.—*Melvor, M. E.* It grows to be a very large tree; flowering time, the beginning of the rains, the seed ripens about the close of the year. The timber will be found useful for many purposes: very little inferior to teak, it seems less liable to split after long exposure and is equally strong, but the wood is heavier. Vessels built in the Ganjam Districts are planked with it; and the door pannels and venetians of the neglected houses at Ganjam are formed of this wood and have stood better than teak similarly situated. Very great caution is requisite in using this wood to obtain it sound. It is more expensive than teak to work and when sawn green the outer planks bend considerably, its price on the Godavery is about 3 annas a foot. This is one among the unlucky woods of the natives though the prejudices against it have in part given way to profit. For general utility, it is superior to any other mahajante wood, a commercial term among the people of the Northern Circars including all wood used for building except teak.—*Rhode M.S.S.*

(6628) PTEROCARPUS SANTALINUS. Red Saunders Wood.

Segapoo chendanum, Tam.	Whonnay Can.
Sal Chundend. Duk.	Racta Chandana. Sans.
Sundel Ahmer. Arab.	Cheudana. Tel. Hind.
Buchum, Pers.	Beng.
	Ract handoon. Cyng.

This is a large, good timber tree, fit for furniture.—*Ains. Mel. Med. page* 210. It is a lofty tree having alternate stalked ternate leaves, petiolate alternate leaflets, smooth above, hoary beneath. The racemes are axillary, simple, or branched, and erect. The legume roundish, stalked, falcate upwards, compressed, smooth, keeled on the lower edge, the keel being membranous and undulated. From this tree is obtained the Red Sandal-Wood, a timber chiefly used by dyers and colour manufacturers of the present day, but which is also used to colour several officinal preparations, such as compound tincture of lavender. Its colouring matter forms beautiful coloured precipitates with many metallic solutions.—*Eng. Cyc.* It is a native of Coromandel, being abundant on the Naggery Hills, Ceylon, Timor, and other parts, the wood is exported to Europe in billets, it is very heavy, sinking in water, extremely hard, of a fine grain and bright garnet red colour which brightens on exposure to the air, it is employed to dye lasting reddish brown colours on wool, it yields its colouring matter to ether and alcohol but not to water, its price in bond in England was in 1882, 13£ to 14£ a ton.—*Rohde, M. S. S.* Dr. Wight says the wood of this tree is brought to Coimbatore in small quantities from Mysore, and sold by weight at an extravagant price. Seen under the microscope, the texture is the same as that of *P. marsupium* the colour only differs. It grows abundantly in the Naggary Hills, yields the "Red Sandal wood" of commerce. It is sold by weight as a dyewood, and forms a regular article of export. It takes a beautiful polish, but the high price of the wood for dyeing purposes, precludes its use as a timber. *M. E. J. R.* Simmonds tells us that *Red Sanders wood* is hard and of a bright garnet red color, and employed to dye a lasting reddish brown on wool. It only yields its color to ether or alcohol. The tree, which is a lofty one, is common in the Madras Presidency and other parts of India: it is also indigenous to Ceylon, Timor, and other Eastern islands. The exports of this wood from Madras in one year have been nearly 2,090 tons. The imports of red Sanders wood from Calcutta and Bombay chiefly into London are to the extent of 700 or 800 tons a year, worth £6 to £9 per ton.—*Simmonds.* In Ajmere, Red Saunders wood is used chiefly in suffumigations to the native gods: is also used in medicine: it is brought there from Delhie, costs ten rupees per maund.—*Gen. Med Top p.* 131. This colouring drug is little used by the Indian Practitioners, though they sometimes recommend it in powder in conjunction with certain herbs, and mixed with Gingilie oil, as an external application, and purifier of the skin, after bathing. The tree grows in abundance in the Bengal provinces on the Malabar coast and also in Mysore, where Dr. Buchanan tells us it is called Whonnay and that the bark contains much red coloured juice.—*Ains. Mat. Med. p.* 42.

(6629) PTEROCARPUS WALLICHII, and Pterocarpus dalbergioides. The gum kino tree, pterocarpus, or padouk, produces a timber which in its finest specimens bears so strong a resemblance to mahogany that a visitor mistook it for mahogany, and recorded it as such in the book of his travels. At Maulmain, it is called red-wood, and one of the trees, for there are the two above species, differs very slightly from the tree which yields the Andaman red-wood, of which Roxburgh wrote: "Wood not unlike mahogany, but more heavy, red, and coarse in the grain. That of the root beautifully variegated, closer grained, and darker coloured."—*Mason.*

(6630) PTEROPLEURA. [GECKOTIDÆ.]

(6631) PTEROPODA, a class of *Mollusca* placed between the *Gasteropoda* and *Brachiopoda* by some writers, and by others next the *Cephalopoda*. The number of species is not large. They pass their entire life in the open sea away from shelter, except that which is afforded by the gulf-weed. In appearance and habits they resemble the fry of the other forms of *Mollusca*. They are supplied with a pair of flippers or wings (hence their name), by means of which they pass rapidly through the water. They swarm in tropical and arctic seas, and are sometimes so numerous as to colour the ocean for leagues. They are the principal food in high latitudes of the species of whale and of sea birds. They are rarely found on the sea-shore, and only one or two species have been accidentally taken in the British seas. "In structure, the *Pteropoda* are most nearly related to the marine univalves, but much inferior to them. Their nervous ganglia are concentrated into a mass below the œsophagus; they have auditory vesicles, containing oolites; and are sensible of light and heat and probably of odours, although at most they possess very imperfect eyes and tentacles. The true foot is small or obsolete; in *Cleodora* it is combined with the fins, but in *Clio* it is sufficiently distinct, and consists of two elements; in *Spiralis* the posterior portion of the foot supports an operculum. The fins are developed from the sides of the mouth or neck, and are the equivalents of the side-lappets (*Epipodia*) of the sea-snails. The mouth of *Pneumodermon* is furnished with two tentacles supporting minature suckers; these organs have been compared with the dorsal arms of the cuttle-fishes, but it is doubtful whether their nature is the same. A more certain point of resemblance is the ventral flexure of the alimentary canal, which terminates on the under surface, near the right side of the neck. The pteropods have a muscular gizzard, armed with gastric teeth; a liver, a pyloric cœcum, and a contractile renal organ opening into the cavity of the mantle. The heart consists of an auricle and a ventricle, and is essentially opistho-branchiate, although sometimes affected by the general flexure of the body. The venous system is extremely incomplete. The respiratory organ, which is little more than a ciliated surface, is either situated at the extremity of the body and unprotected by a mantle, or included in a branchial chamber with an opening in front. The shell, when present, is symmetrical, glassy, and translucent, consisting of a dorsal and a ventral plate united, with an anterior opening for the head, lateral slits for long filiform processes of the mantle, and terminated behind in one or three points; in other cases it is conical, or spirally coiled and closed by a spiral operculum. The sexes are united, and the orifices situated on the right side of the neck. According to Vogt, the embryo Pteropod has deciduous vela, like the sea-snails, before the proper locomotive organs are developed.—*Huxley.*

"From this it would appear that while the *Pteropoda* present some analogical resemblances to the *Cephalopoda*, and permanently represent the larval stage of the sea-snails, they are developed on a type sufficiently peculiar to entitle them to rank as a distinct group; not indeed of equal value with the *Gasteropoda*, but with one of its orders.

"This group, the lowest of the univalve or encephalous orders, makes no approach towards the bivalves or acephala." (Woodward, 'Treatise on Shells.')

De Blainville divides this group into two sections, *Thecosomata* and *Gymnosomata*:—

A. Thecosomata.—Animal furnished with an external shell; head indistinct; foot and tentacles rudimentary, combined with the fins; mouth situated in a cavity formed by the union of the locomotive organs; respiratory organ contained within a mantle cavity. This section embraces two families, *Hyaleidæ* and *Limacinidæ*. *B. Gymnosomata.*—Animal naked, without mantle or shell; head distinct; fins attached to the sides of the neck; gills indistinct.—*Eng. Cyc.*

(6632) PTEROSPERMUM (from the Greek word πτερόν, signifying a wing, and σπέρμα a seed), a small genus of Plants belonging to the natural order *Byttneriaceæ*, which is found in the Indian Isles and the southern parts of India. The flowers being large and the foliage showy, have induced the cultivation of the species as ornamental trees all over India. The calyx is leathery, 5-partite, tomentose outside, hairy within; petals 5, shorter than the calyx; stamens 20 (5 sterile), united at the base into a column with the stalk of the ovary; style slender, club-shaped; seeds winged. The genus is small, but all the species form handsome trees, and, like most of the plants of the nearly allied order of *Malvaceæ*, abound in mucilage.—*Eng. Cyc.*

(6633) PTEROSPERMUM ACEROIDES,
Thamajamwai-zeke, BURM.

(6634) PTEROCARPUS SUBACERIFOLIUM.
Najee, BURM.

(6635) PTEROCARPUS ACERIFOLIUM.
Najee. BURM.

These three species of large timber are found growing along with Teak in all the Pegu Forests. The two first are plentiful, but the third kind is scarce. This timber is extremely valuable and is as strong as either Teak or Oak. Its durability for purposes of ship-building has never been tested, because it has never been desicated or killed like the Teak. It attains a girth of ten or twelve feet and rises to a lofty height: It has a dark-brown wood.—*McClelland.*

(6636) PTEROSPERMUM HEJNIE, LOLOOGA WOOD.

Lolooga kurra, TEL.

(6637) PTEROSPERMUM INDICUM, KYABOOCA. This wood is obtained from the knotty excrescences or burrs of Pterospermum Indicum? it is sawn off in slabs—2 to 4 feet long and 2 to 8 inches thick. It resembles the hue of the yew is very hard and full of curls—the colour being reddish brown, varying to orange. It is very ornamental, and much esteemed in China, India and England, where it is used for making small boxes, writing desks and other fancy ornamental work. The wood is brought to Singapore by Eastern traders, and is sold by weight.—*M. E. J. R.*

(6638) PTEROSPERMUM SUBERIFLORUM.

Taddee Marum, TAM.

A native of the mountainous tracts all over India. Flowering time the beginning of the hot season. Trunk erect, growing to be a timber tree of middling size. The wood is white and too soft to be of much use.—*Rhode M.S S.*

(6639) PTYCHOTIS, a small genus of Umbelliferous Plants, of which the seeds of some of the species have formed articles of condiment and of medicine from very early times. The genus extends from the south of Europe, through the Oriental region, to all parts of India. The calyx is 5-toothed; petals obovate, bifid, or emarginate, with a long inflexed point. Fruit compressed laterally, ovate or oblong. Seed roundish or flat before and convex posteriorly. The species are annual or biennial plants. Stem-leaves usually cut into numerous capillary segments. Flowers white, disposed in compound umbels, of which the involucels are many-leaved, and the involucre either wanting or few-leaved. The European species are not remarkable for any useful properties, the *P. copticum* and *P. Ajowan* probably yielded the seeds which formed the 'Ammi' of the ancients. Botanists and inquirers into the plants, condiments, and medicines of the ancients, have usually sought too exclusively in Europe for what was frequently derived from the East. Dioscorides states that the Ethiopic Ammi is called Cumin by some, and that it is thought to be distinct from the royal kind. The seeds of one kind were sent by Forskal to Linnæus, who named the plant *Ammi copticum*. This has now been removed to the present genus *Ptychotis*. Arabian authors give Nankhwah as the synonym of Ammi, and Persian authors consider Ajwain to be a synonym of the former. It is remarkable, according to Dr. Royle, that there is also an Indian plant which is everywhere called Ajwain, and celebrated for its aromatic smell, pungent taste, and for its employment both by natives and Europeans for culinary and medicinal purposes; so much so, that Dr. Roxburgh could not conceive that "this famous Indian plant should be unknown to European botanists." Dr. Royle says, "in Persian works in use in India the Arabic Nankhwah is given as a synonym of the Indian Ajwain, as it is also of the Greek Ammi." The Indian species has been referred by De Candolle to the genus *Ptychotis*, and called by him *P. Ajwan*, stating that it was very closely allied to *P. coptica*, which we have seen was considered to be one kind of Ammi—the two kinds described by Dioscorides being *Cuminum Æthiopicum* and *C regium*. The latter name is translated by the Persians 'Kamoon Mullooke,' or Royal Cumin, and given as a synonym of the Nankhwah. The Indian and Egyptian kinds of *Ptychotis*, as ascertained by modern botanists, are therefore most probably the two kinds of Ammi of Dioscorides. These afford interesting instances of the results to be obtained by closely examining the products of nature possessed of any remarkable properties, in the countries where they are produced, and continue to be used, and whence they were probably first obtained by the ancients. *Eng. Cyc.*

(6640) PTYCHOTIS AJOWAIN, *Roxb. Fl. Ind. ii.* 91. *Syn.* Ligusticum Ajwain, (Fleming. As. Res. xi. p. 170). Sison Ammi, of *Ainslie*.

Ajoumin, Jugnance, BENG. and HIND.	Nankhah, PERS.
	Amoos, ARAB.

Cultivated in India every where. This is one of the most useful of the Umbelliferæ, and an excellent remedy in flatulant colic; much used in India. (*Roxb.*)—*O'Shaughnessy, p.* 357-58.

(6641) PTYCHOTIS COPTICA. (Coptic ammi) Egypt and Candia. Used as a stimulant aromatic.—*O'Shaughnessy, page* 357.

(6642) PTYCHOTIS INVOLUCRATA. *Ameeson* of North India, *Chanoo* and *Radhooni* of Bengal, used as a substitute for parsley. *Royle.*—*O'Shaughnessy, page* 358.

(6643) PTYCHOTIS SYLVESTRIS, Arub Ajwain, *Royle*, found in the Khadir lands of the Saharunpore district. Used as a stomachic, aromatic, and remedy in flatulence.—*O'Shaughnessy, page* 358.

(6944) PULICARIA, a genus of Plants belonging to the natural order *Asteraceæ*. It has an involucre laxly imbricated in few rows. The pappus in two rows, the outer one short, cup-like, membranous, and toothed, the inner one pilose.—*Eng. Cyc.*

(6645) PUNICA, a genus of Plants belonging to the natural order *Myrtaceæ*, sometimes distinguished, in consequence of its having two verticels of capsules developed instead of one, from *Myrtaceæ* under the name of *Granataceæ*. The genus consists of only a single species, the celebrated Pomegranate, with a dwarf variety which is sometimes considered a distinct species. The pomegranate has from the earliest period formed an object of attraction in the countries

from Syria to the north of India, where it grows in perfection, as well as in the north of Africa; and this, as well from its shining dark-green foliage, as from its conspicuous flowers, of which the flower-cup and petals are both of a crimson colour, while its large red-coloured fruit, filled with juicy pleasant-flavoured pulp, which covers its numerous seeds, makes it an object of desire in hot countries. Thus we find it mentioned in the Bible under the name Rimmon (Numbers, ch. xiii.), and we hence learn that it was cultivated in Egypt and also in Palestine; by the Arab authors it is called Rooman, and by the Persians Anar, and it is probably indigenous all along the mountains from the Caucasus to the Himalayas, where it is described by Dr. Royle as being found in a wild state. Forster describes the Pomegranate as being delicious in most parts of Persia; and Burnes states that the famous Pomegranates without seeds are grown in gardens under the snowy hills near the Cabul River. The Pomegranate was well known to the Greeks, being the Poa of Theophrastus and the Poia of Dioscorides. Hippocrates mentions it by what is supposed to be its Phœnician name, Side. By the Romans it was called *Punica*, and *Punicum Malum*, from having been introduced from Carthage. Besides the fruit, the parts employed by the ancients were the double flowers, which were called balaustion, the pericarp, from its leatherly consistence, called malicorium, was used for its astringent properties; while the bark of the root was considered an efficient anthelmintic. In the East, where so much has remained stationary, the different parts continue to be employed for the same purposes; and Dr. Royle mentions that in India buloositon is given as the Greek name of the double flower. The rind of the wild fruit is much preferred for astringent purposes, and forms in the present day an article of commerce from the Himalayas to the plains of India. The bark of the root, being also still employed in India for the expulsion of intestinal worms, was made known as a recent discovery in India, in consequence of a Mohammedan practitioner having cured a European gentleman there of tape-worm with great ease. He had no doubt learned this property of the bark of the pomegranate from the translations of Dioscorides which are incorporated in most of the Mohammedan works on Materia Medica, affording a striking instance of facts, once well known being forgotten until they are rediscovered. It is remarkable that the African slaves in the West Indies are also acquainted with this property of the root of the pomegranate, which they must have learned in their own country, probably from the prevalence there of Mohammedan works on medicine, or of the practice which is inculcated in them.—*Eng. Cyc.*

(6646) PUERARIA TUBEROSA, (Hedysarum tuberosum of Roxburgh), Shimeeya batra-jee, *Beng.* a native of the Circar mountains, the bruised root is used as a poultice to swellings of the joints.—*O'Shaughnessy, page* 316.

(6647) PULLICATES. Cotton checked handkerchiefs, of various colours.—*Faulkner.*

(6648) PULPUL, *Hind.* MYRTUS PIMENTA. Allspice. This is imported.—*Riddell.*

(6649) PULQUE. The saccharine and mucilaginous sap of the Agave americana may be made to flow by incisions in the stem: it readily ferments, and in Mexico yields on distillation an agreeable ardent spirit, called vino mercal. The incisions are made just before the flower scape is ready to burst. The dried flowering stems of A. americana also afford an almost impenetrable thatch; the fresh green leaves are cut up and given to cattle, and the centre of the flowering stem, split longitudinally, is by no means a bad substitute for a European razor strop, owing to minute particles of silica forming one of its constituents. The two products most deserving attention however are the extract which forms a lather like soap, and the fibre known in Southern India as the pita. The Mexicans also make their paper of the fibres of Agave leaves laid in layers.

(6650) PULSES. The generic name in Malay and Javanese for all leguminous plants, is kaching, by adding an epithet to which we have the name of the species. Several species are regular objects of cultivation, as Phaseolus max, lunatus and radiatus; Dolichos kachang; Lablab vulgaris; Soja hispida; Cytisus cajan, and Arachis hypogæa.—*Crawfurd, Dict. p.* 361.

The following are the Pulses Cultivated in Madras as Food for Man or Beast.

Botanical Name.	English Name.	Hindoostanee Name.	Tamil Name.
Medicago sativa,.....	Lucern, ...		
Trigonella fœnum græcum,.....	Fenugreek, ...	Maitee or meetee bajee,	Vendium.
Psoralea corylifolia,.....	Hazel-leaved psoralea,...	Bawurcheen, ...	Karpooga Arisee.
Cicer arietinum, ...	Chick pea, Bengal gram,	Chenna, ...	Cadalei.
Ervum lens, ...	Lentil, ...	Moosoor, ...	Mussoor purpoo.

Botanical Name.	English Name.	Hindoostanee Name.	Tamil Name.
Pisum sativum, ...	Common pea,...	Butan,...	Puttani.
Phaseolus vulgaris, ...	French bean, ...	Bakla, ...	French beanoo.
Phaseolus lunatus, ...	Duffen bean, ...		
Phaseolus radiatus, ...	Green gram, ...	Haree moong, ...	Putchay payroo.
Phaseolus mungo, ...	Moong or moonsh, ...	Marh, ...	Oolandoo.
Dolichos uniflorus, ...	Madras gram, ...	Kooltee, ...	Kolloo.
Dolichos sinensis, ...	Chinese dolichos, ...	Suffeed lobea, ...	
Lablab vulgaris, ...	Bullar, ...	Sainkaputtee, ...	Mutchay cottay.
Psophocarpus tetragonolobus, ...	Winged pea, ...	Pank ke mutur, ...	
Canavalia gladiata, ...	Sword bean, ...	Lal kudsumbah, ...	Segapoo Thumbotten.
Cajanus indicus, ...	Pigeon pea,..	Toor dhal, ...	Thovaray purpoo.

M. E. of 1857.—Most of these may be referred to under their several heads.

(6651) PULWUL. Trichosanthes Dioica. Dioecous Snake Gourd. This is one of the snake gourd species, of a small description, the size of an egg: the seed is sown in the cold season and yields fruit from March to September.—*Riddell.*

(6652) PUMMICE STONE.

Poosa ray, Tel.	Pietra pomice, It.
Pierre ponce, Fr.	Pumex, Lat.
Brimstein, Ger.	Piedra pomez, Sp.

A light spongy, vitreous stone, found usually in the neighbourhood of volcanoes, and supposed to be a lava or volcanic glass. It is used for polishing metals and marble, and smoothing the surface of wood and pasteboard. Pumice is quarried and exported in large quantities from Lipari and the Isles Ponxa, in the Mediterranean.—*Faulkner.* Pummice stone in small pieces and very hard is found on the Sea Coast near Nezampatam.—*Rohde, M.S.S.*

(6653) PUMPKIN, Red and White.

Kuddoo, Hind.

This vegetable grows in great abundance in all parts of the Deccan. It is much esteemed both by the Europeans and natives. It is generally sown at the commencement of the rains, and requires no particular care; the soil should be light and good. When young, about the size of a goose egg; if cut and boiled, it will be found to resemble the artichoke-bottom dressed in the same way.—*Riddell.*

(6654) PUMPKIN, White, or White gourd, or pumpkin. *Benincasa cerifera.* The Karens and Burmese cultivate a species of pumpkin or gourd, never eaten by Europeans, which they esteem a valuable addition to their curries. —*Mason.*

(6655) PUNA or POON. This wood is commonly called Peon in England. It is used for masts, yards, &c.; is the wood so much spoken of by persons from Ceylon. It certainly is of a good quality, and superior to that of Malabar; but, from its small dimensions, its scarcity, and the trouble in obtaining it, is of little consideration. The largest said to have been found was eighteen inches in diameter, and sixty feet in height; but the largest Edye could discover was not more than nine inches in diameter, and thirty-five feet high. In quality it is much the same as the first sort in Malabar, which may be obtained at Mangalore from the native merchants at all times when the coast is open (viz. from November to April), of three feet in diameter, and one hundred and ten feet long for the sum of 150*l.* sterling.—*Edye. Ceylon.*

(6656) PUNDE CYANN, the Tamil name of a Ceylon tree which grows to about twenty inches in diameter, and twelve feet in height. It is a close grained wood and resembles the English pear tree. It is used by the natives for various purposes in making farming utensils.—*Edye, Ceylon.*

(6657) PUNGUL, the Tamil name of a tree which grows to about eighteen inches in diameter, and twelve feet in height. It is of little use. Its fruit, and also its juice, are used as applications to ulcers, &c. From the seed a fixed oil is prepared which is considered valuable in rheumatic pains, bruises, &c.—*Edye. Ceylon.*

(6658) PUNICA GRANATUM. (Pomegrante.)

Darimba, Sans.	*Parts used.*
Dalim, Darim, Beng	Fructus Cortex.
Anar, Gulnar, Hind. Pers. & Duk.	Baccæ tunica exterior, D.
Buloositoon, Rooman, Yunani.	Rind of the Fruit,
Madalum pullum. Tam.	Granati Radix, E.
Rana, Arab.	Radicis Cortex, D.
Dadima pundoo, Tel.	Flores, D.
Rumom paio, Mal.	Flowers of the Pomegranate. *Icosandria Monogynia*, Linn.
Delima, Malay.	

The Pomegranate, a native of the mountainous countries from Syria to the north of India, must always have been an object of attention. It is the *rimmon* of the Bible, and the *rooman* of the Arabs. It was well nown to the Greeks

and Romans.—*Royle.* A native of Cabul, Bokharra, Mezenderan and Asia Minor generally; common now in almost all warm climates; the best fruits are those of Balabagh, lying under the snowy hills, near the Cabul river. Very large quantities are annually imported into the north of India from Cabul, and Cashmere. In the Himalayas and the *plaines* the pomegranate also occurs, but of inferior quality; the fruit is small, and is sold in the Bazar under the name of *darmee*; the rind, *nas Pal*, is used in medicine and in dyeing, on account of its great astringency.—*O'Shaughnessy.*

Stem arborescent and irregular in arid situations rather thorny; the leaves usually opposite, often fascicled, oblong inclining to lanceolate, quite entire, not dotted, smooth, shining, and of a dark green; flowers commonly solitary, of a brilliant scarlet; calyx thick and fleshy, adhering to the ovary, turbinate, 5 to 7 cleft; petals 5 to 7, crumpled; stamens numerous, often double; style filiform; stigma capitate; fruit of the size of a large apple, with a thick leathery rind, and crowned by the tubular limb of the calyx; cells several, arranged in two strata, separated from each other by an irregular transverse diaphragm, lower division of 3 cells, the upper of from 5 to 9 cells; seeds numerous, involved in pellucid pulp, with foliaceous, spirally convolute cotyledons.—Nees von E. 301.

The parts of this plant which were employed by the ancients, still are so in the East, and are officinal in the D. P. Thus the Flores, D. are the *Balaustion* of the ancients. In India, *buloosi toon* is given as the Greek name of the double flower. They are devoid of odour, but have a bitterish and astringent taste, tinge the saliva of a reddish-colour, contain Tannin, strike a black with ferruginous salts. The Rind of the fruit (*Granatum*, L.; *Bacca Tunica exterior*, D.) especially of the *wild* plant, is extensively employed as an astringent and as a dye in the East. It is of a reddish brown colour and smooth externally, but yellow on the inside; usually in irregular fragments, dry, hard, and leathery, of a very astringent taste. It contains of Tannin 18.8 per cent, with 10.8 of Extractive, and 17.1 of Mucilage, and is used for tanning in some countries. The Bark of the Root (*Radicis Cortex*) was employed as an anthelmintic by Dioscorides and by Celsus, and still is so in India. It was reintroduced into practice by Drs. Buchanan and Anderson. The root itself is heavy, knotted, and of a yellow-colour; its bark often sold in strips, sometimes with parts of the root still adhering to it. On the outside of a greyish-yellow colour; on the inside, yellow, something like that of the barberry. It has little smell; when chewed, colours the saliva yellow; has an astringent taste, without any disagreeable bitterness. It has been analyzed by Metouart and Latour de Trie, and others; but the source of its peculiar anthelmintic powers has not been discovered, and the subject requires further investigation. It contains Tannin (about 20 per cent.), Gallic acid, Resins, Wax, Fatty matters, and Mannite. "An infusion yields a deep-blue precipitate with the salts of Iron, a yellowish-white one with solution of Isinglass, and a greyish-yellow one with Corrosive Sublimate, and Potash or Ammonia colours it yellow." (*c.*) It is apt to be adulterated with the barks both of box and of barberry. The former is white and bitter, but not astringent; the latter yellow, very bitter, and not thus affected by the above four reagents. All parts are astringent, the rind of the wild fruit especially so, and useful in Diarrhœa and advanced stages of Dysentery; the Flowers in infusion slightly astringent; the Bark of the Root astringent, but remarkably useful as an Anthelmintic against tænia. It may be given in doses of one scruple in powder; or a decoction may be formed by steeping for 12 hours *fresh Root-bark of Pomegranate.*—*Royle.* The *pericarp* is hard, smooth, a line in thickness, olive brown externally, yellowish within, inodorous, externally bitter and astringent, much used in tanning and in dyeing yellow; also as a medicinal astringent. The juice of the fruit is acidulous and sweet, and makes a pleasant sherbet for fever patients.—*O'Shaughnessy, pages* 338, 339. The Seeds, Dried, *Anardan*. *Naspal* of Punica granatum; the Pomegranate, with their fleshy envelopes are sold, and used in sherbets: all are plentiful at Ajmeer, considered cooling. Naspal is the bark of the fruit, and is only used in dying. The bark of the root though strongly purgative is not used in medicine. Large quantities of fine pomegranates are annually brought from Cabul to Ajmeer.—*Gen. Med Top. p.* 125. In the Dekhan there are two varieties of this tree, bearing white and red fruit—both sweet, but much inferior to the dried brought from Persia and Bussorah to the Bombay market. The tree grows easily from seed, and large fine juicy fruit, where the soil is good, is often produced. There is a variety which is generally sour, used by the Natives for sherbet. The dried bark of the root is made into a decoction and given for worms. By a continuation of layers from successive plants the fruit becomes almost seedless.—*Riddell.*

(6659) PUPA. In Entomology this term is applied to the third stage of existence of an insect, the egg being the first stage, and the larva or caterpillar, the second.—*Eng. Cyc.*

(6660) PUPIVORA. In Entomology this term is applied by Latreille to his second great section of hymenopterous Insects—a section the species of which are distinguished by their having the abdomen attached to the thorax, in most cases, by a slender stalk, and not, as in the first section (*Securifera*), forming as it were a continuation of the thorax. The females are

furnished with a slender bristle-like ovipositor, and in this respect they also differ from the greater portion of the *Securifera*. The larvæ of the *Pupivora* have no feet, and most of them are parasitical. Latreille divides this section into two groups, the *Evaniales* and the *Ichneumonides*, distinguished chiefly by the insertion of the stalk or basal portion of the abdomen. In the *Evaniales* the stalk is attached to the thorax, and in most cases immediately under the scutellum; they have distinct nervures to the wings, and those of the upper pair form cellules; the antennæ are filiform, or setaceous, and composed either of thirteen or fourteen joints; the mandibles are toothed on the inner side; the maxillary palpi have six joints, and the labial four; the ovipositor is generally exserted, and composed of three slender pieces. Dr. Leach regarded the present group as constituting a family, and applied to it the name *Evanidæ*; compared with the next section of the *Pupivora*, the present one is very limited in species. Mr. Stephens, in his 'Systematic Catalogue of British Insects,' only enumerates five species, and these constitute three genera, *Evania*, *Brachygaster*, and *Fœnus*. In the *Ichneumonides* the abdomen has its origin between the two posterior legs; the nervures of the upper wings form cellules; the antennæ are generally filiform or setaceous, and composed of many joints (sixteen at least); the mandibles are in most cases destitute of denticulations on the inner side, and are bifid at the apex; the maxillary palpi are always distinct, and seldom have more than six joints. Of this group the species are exceedingly numerous. Mr. Stephens states that he possesses 800 British species of this family. The *Pupivora* appear to be destined to prevent other tribes of insects (particularly the *Lepidoptera*) from becoming numerous. The *Ichneumonidæ* may be seen during the summer months in great numbers flying from plant to plant in search of the caterpillars which are suited to furnish the proper food and to rear their larvæ, each caterpillar apparently having its own peculiar parasite, or parasites, for sometimes several species of Ichneumon attack the same larvæ. The female Ichneumon, by means of her long bristle-like ovipositor, inserts her eggs in the body of the caterpillar in such a manner, and in such parts, that it does not destroy the life of the victim. In most cases these eggs are not hatched until the caterpillar has changed into a chrysalis; they then hatch, and the Ichneumon larvæ feed upon the contents of the pupa case, inclose themselves in silken cocoons, and undergo their final transformations, to come forth in proper season, eating their way through the chrysalis case. Instances are not uncommon in which the eggs of the Ichneumon hatch in the body of the living caterpillar, and, what is most remarkable, they do not destroy its life. It is not until the larvæ have quitted their abode in the caterpillar that it dies, having the cocoons of the Ichneumon larvæ attached to its skin. The caterpillar so abundant on cabbages, and which is that of the common white butterfly, affords a familiar example of this nature. At certain times of the year numbers of those caterpillars may be seen on walls adjoining gardens: on these they usually attach themselves (in some sheltered situation) to undergo the transformation into the pupa state. One of these caterpillars will appear healthy, select a convenient situation, attach itself (as usual before the change into the pupa state) by means of a silken thread around its body, but instead of undergoing the transformation, we shall find it after a short time covered with an immense number of small yellowish silken cocoons spun by the larvæ of the Ichneumons as they crawl from its body.—*Eng. Cyc.*

(6661) PUPLI CHUCKAY. The bark of the Pupli root yields an orange dye, and is treated with alum, Myrobolans, &c. This dye was exhibited from Bellary, Mysore and Salem, at the Madras Exhibition of 1855. It was noticed by Buchanan (Mysore 1. p. 168.) and was named by him somewhat doubtfully as Ventilago? a Rhamnaceous genus. Flowering or fruit bearing specimens of this scandent shrub have not been procured to settle the point in question.—*M. E. J. R.*

(6662) PUPUNHA TREE, Guilielma speciosa, Mart., is the Piritu or Pirijao of Venezuela, the Pupumha of the Amazon district, and the Paripou of Guiana. It is a palm, of an intensely hard wood, sharp needle like spines are thickly disposed in rings or bands, round its slender cylindrical trunk. The Indians subsist for months on its farinaceous fruit.—*Seeman.*

(6663) PUREE, a beautiful yellow Chinese pigment, in the composition of which the urine of the Elephant is said to be a chief ingredient. It is brought to China in round lumps of various sizes in colour like orpiment, with a strong urinous smell, and little or no taste.—*Morrison.*

(6664) PURSLANE. Portulaca Sativa and Oleracea.

Choolee, Hind.

Round stem, fleshy leaves, and slightly acid. It is used as an ingredient in salads. It is reared by seeds sown at the commencement of the rains, and will thrive in any soil.—*Riddell.* Leaves of a succulent nature harmless, tastless, and inodorous, many varieties are cultivated on the plains for their pretty flowers, raised from seed. —*Jaffrey.* Purslane is as common a weed in the Tenasserim Provinces as it is in America, and is used by the natives for a pot-herb.—*Mason.*

(6665) PUTCHAPAT. This is a well known article in Bengal. Its source was long doubtful. We extract the following notice regarding

it by Dr. Wallich, from the Transactions of the Medical and Physical Society of Calcutta for 1835. Dr. Wallich has also kindly favoured us with an additional note on the subject. "I shall now advert to another vegetable substance which, although most extensively used by the natives of this country, has hitherto continued one of the problems in our Indian Materia Medica. The drug to which I allude, is called in Bengallee as well as in Hindee, *Pucha Pat*, and is found in every bazar, almost throughout Hindustan. My esteemed friend Baboo Radhakant Deb informs me, that "there exists no Sanscrita name for this leaf, which is largely imported by Mogul merchants; that it is used as an ingredient in tobacco for smoking, and for scenting the hair of women, and that the essential oil is in common use for imparting the peculiar fragrance of the leaf to clothes among the superior classes of natives." I believe that the people of the peninsula are peculiarly fond of this perfume, as are also the Roman Catholic inhabitants of this country generally. *O'Shaughnessy, page* 493.

(6666) PUTCHUCK; PUTCHUK: AUCKLANDIA: COSTUS ARABICUS. ARABIAN COSTUS, OOPLATE, KOOT.

Kust, ARAB.	Sepuddy, MAL.
Koot, Ooplate, GUZ. HIND.	Kostum, Putchuck, TAM
Kushtam, SANS.	Changala, Kostom, TEL. *Faulkner.*
Putchuck, HIND	Koost i-Hindee and Koost i. ARABEE. PERS.
Goin mahanel, CYNG.	Pucha, MALAY.
Kooth, HIND.	
Koostus, GREEK.	
Kooshta, SYRIAC.	

Is the name by which a fragrant root is designated in the price-currents of Calcutta and Bombay, whence it is exported to Canton, being highly esteemed by the Chinese as an incense. From the places of export this would appear to be a product of India, but neither the plant which yields it nor the place where it grows were discovered until very recently. The discovery is interesting, as the Putchuk is a substance which was known to the ancients. Dr. Royle, while in the north-western provinces of India, obtained a root which formed a considerable article of commerce, and which was said to be brought from still farther north, that is, from Lahore. It was warm and aromatic in taste, fragrant in odour, and frequently called Orris-Root (Iris-Root) by Europeans in India, though by the natives in Northern India it is called Kooth. On comparing specimens of Kooth which he obtained in Northern India with what was called Putchuk in Calcutta, he found that they were identical, and he was subsequently informed by Mr. Beckett, who was long settled as a merchant in Northern India, that what the latter purchased from Umritseer under the name of Kooth he sold in Calcutta by that of Putchuk, so that there can be no doubt of the identity of the two substances; but all that had been ascertained with respect to the place where it was produced was, that it seemed to be to the north of the Sutlej. Kooth, being used in India as a medicine, as well as exported to China, is described in the Persian works on Materia Medica in use in that country, and has assigned to it Kust as the Arabic, Kooshta as the Syriac, and Koostus as the Greek name. Three kinds are described. Dr. Royle states that he was only able to meet with two kinds in India, one called Koost-Hindee, and the other Koost-Arabee. These evidently refer to two of the three kinds of Costus described by Dioscorides as the Arabian, Indian, and Syriac. ('Illust. Himal. Bot.,' p. 360.) There can be little doubt therefore that the Kooth or Putchuk is one of the kinds of Costus of the ancients, which was highly esteemed by them, and formed an ingredient in their most famous compound alexipharmic confections, such as the Theriaca and the Mithridatium. It was also highly esteemed by them as an incense, as, in the line of Propertius—"Ure puer costum Assyrium redolentibus aris"; and is mentioned by Horace as 'Achaemenium costum.' ('Od.,' iii. 1.) The identity of Kooth and Costus was however long ago ascertained, though not generally known, as is evident in the following passage from Garcias ab Horto, in Clusius ('Exot.,' lib. x.) "Est ergo Costus dictus Arabibus Cost aut Cast: in Malacca, ubi ejus plurimus est usus, Pucho, et inde vehitur in Sinarum regionem." In MacCulloch's 'Commercial Dictionary,' Putchook is described as "the root of a plant growing in Sinde. When burned it yields a fine smell. The Chinese beat it into a fine powder, which they burn as incense in the temples of their gods." Of the Putchuk, 6697½ bazar maunds, of the value of 99,903 rupees, were exported from Calcutta in the year 1837-38. On Dr. Falconer's proceeding on his journey to Cashmere, Dr. Royle requested him to make inquiries respecting this substance, and he discovered that it was exported from the valley in large quantities to the Punjab, whence it finds its way to Bombay and Calcutta; and that it is sold in China at an advance of about 300 per cent. on the price at which it is gathered in Cashmere. Dr. Falconer subsequently found it growing in great abundance all round the elevated summits of Cashmere. From the plants with which it is associated, and the circumstance under which the Koot grows, being one of the *Compositæ*, or Thistle tribe with feathered seed, of which when once established the dissemination becomes easy, Dr. Falconer has no hesitation in thinking that it could be produced to an unlimited extent, of the best quality, in the Himalayas at elevations of from 7500 to 9000 feet above the sea, and that the Choor Mountain alone

might be brought in a few years to produce thousands of maunds of it. Preparatory to diffusing the Koot, or Costus, he has introduced it into the Himalayan nursery attached to the Saharunpore Botanic Garden. Finding that it belongs to a new genus, he has named it *Aucklandia*, in honour of George, earl Auckland, governor-general of India, "as a distinction well merited by his lordship's services in the cause of Indian Botany."—(*Royle, on the Productive Resources of India.*) Costus Arabicus: is supposed to be the root of the Aucklandia costus, a genus of the thistle tribe. It is grown in the mountains of Cashmere, where it is called Koot, is a gregarious herb, six or seven feet high. Its roots are dug up in September or October, chopped up into pieces from two to six inches long and exported without further preparation. The greater portion being sent via the Punjab to Bombay, whence it finds its way to the Red Sea, Persian Gulf and China. Another portion being sent across the Sutlej and Jumna to Hindustan. In Cashmere the cost of its collection and transport to a mercantile depot, is about 2s. 4d per cwt., but at Jugadree on the Jumna, it has increased to about 16s. 9d. or 23s. 4d per cwt. and in the Chinese ports it fetches nearly double that price the cwt. The Chinese burn the roots as incense in the temples of their gods, and they also attach great efficacy to it as an aphrodisiac. The imports into Canton in 1850 were 854 piculs, valued at 5,150 dollars. In Cashmere it is chiefly used for the protection of bales of shawls against insects. The exports for Calcutta average about £1,500 annually.—*Simmonds*

(6667) PUTRANJIVA, an Indian genus of Plants, referred by Dr. Roxburgh to *Nageia*, but which has been separated by Dr. Wallich under the above name, which is a Sanscrit compound, consisting of the words, 'pootra,' a son, and 'jeeva,' life, in consequence of the seeds being strung by parents round the necks of children, under the supposition that they will preserve them in health. They are sold in bazars throughout India for this purpose. ***P. Roxburghii***, the only species known, forms a large timber-tree, with an erect straight trunk, and a white close-grained very hard wood. The head is large and shady, composed of numerous spreading branches, with shining dark green leaves arranged on two sides of the branchlets. The flowers are dioecious, the male ones crowded together; the perianth small, calyx-like, 4-5-leaved; corolla none; stamens three; filaments thread-like, all or only two united together, and the third free. The female flowers solitary in the axils of the leaves, with long foot-stalks; perianth 5-leaved; ovary ovate, oblong, 3-celled; cells 2-seeded; styles three, filiform; stigmas crescent-shaped and toothed; drupe 1-seeded. Young plants of this tree have been cultivated in moist stoves in Britain. The genus has been referred to the natural family of *Myricaceæ*, but is considered by Endlicher as more nearly allied to the *Antideæmeæ*.—*Eng. Cyc.*

(6668) PUTRANJIVA ROXBURGHII. Wall. Tentam. p. 61. Nageia Putranjiva, *Roxb. Fl. Ind.* iii. p. 766. Royle's Illust. 100.

Curroopallay marum, Tam.

Though generally diffused throughout India, Dr. Wight had not seen this tree, but Roxburgh describes it as a large timber tree with an erect straight trunk. The wood is white, close grained and very hard.—*Wight.* Coromandel, Patna, Monghir hills, and from Sylhet to the Kheree jungle. The Sanscrit name is compounded of *pootra*, a son; and *jeeva*, life. The Hindoostani name *jeeapootra*, is similarly derived. The nuts are strung by parents round the necks of their children, to keep them in health. *Roxb.*—*O'Shaughnessy, page* 611.

(6669) PUTTY. An ordinary name for the peroxide of tin, generally used for polishing mirrors and lenses, and for rendering glass white and opaque, converting it into enamel; and for other purposes in the arts.—*Waterston.*—*Faulkner.*

(6670) PUTTY GLAZIERS. Is prepared by kneading chalk with linseed oil.

(6671) PUTWA OF BHAGULPORE, a bast.

(6672) PYGATHRIX, M. Geoffroy's name for the Douc, or Cochin-China Monkey (*Lasiopyga*, Illiger). It has the following characters:—Head rounded; muzzle moderately prolonged; tail long; cheek pouches; hands longer than the fore arms and the legs; anterior thumbs very short and slender; no callosities; buttocks fringed with long hairs.

Dental Formula.—Incisors, $\frac{4}{4}$; Canines, $\frac{1-1}{1-1}$; Molars, $\frac{5-5}{5-5} = 32$.

(6673) PYGATHRIX NEMŒUS, Geoff. (*Lasiopyga Nemæus*, Ill.; *Simia Nemæus*, Linn., Mant.). This very rare monkey is perhaps the most remarkable of the whole tribe for the variety and liveliness of the colours with which it is marked, and which are the more striking from being distributed in large masses. The upper part of the head is brown with a dark-reddish chestnut frontal band. The cheeks are clothed with very long and whitish or yellowish-white hairs. The back, the belly, the arms, and the sides are gray with a somewhat greenish cast; the tail is whitish, and so are the rump and the fore arms; the anterior fingers are blackish; the hips and thighs are blackish, and the legs of a brightish-red chestnut; the more exposed parts of the face are of a reddish tint. Length rather more than 2 feet when erect; length of tail about 1 foot 7 inches. It is a native of Cochin China.—*Eng. Cyc.*

(6674) PYGIUM ACUMINATA, Scarce, but found on the banks of streams in the Tounghoo district, attaining a girth of five or six feet, red wood, adapted to cabinet making.—*McClelland.*

(6675) PYLORIDIA, *Pyloridea*, M. De Blainville's name for his ninth family of *Lamellibranchiata*, which he thus characterises:—Body compressed, more and more cylindrical, the mantle more and more closed and prolonged backwards by two long tubes which are ordinarily distinct, with an anterior and inferior aperture for the passage of a very small and ordinary conical foot; branchiæ narrow, free, and prolonged in the tube.

(6676) *Pandora Obtusa*, is an abundant British species.

(6677) *Anatina*. Animal oblong, rather thick, having the mantle closed by a rather large membranous lamina with a small rounded aperture at the antero-inferior part for the passage of a linguiform foot; two elongated tubes separated deeply at their extremity, the lower being rather greater than the upper; branchiæ narrow, free, and pointed backwards. There are 20 living species known. They inhabit India, the Philippines, New Zealand, and Western America. There are 50 fossil from the Devonian and Oolitic Rocks. *Periploma*, *Cochlodesma*, and *Cercomya* are sub-genera.

(6678) *Anatina Subrostrata*, has the shell ovate, membranaceous, anterior side attenuated and subrostrated. It is a native of the seas of Australia. Lamarck adds, the Indian Ocean. The *Anatinæ* have hitherto been found for the most part in sands and shallow water.

Lutricola.—Body oval, very much compressed or subcylindrical, the mantle only closed in the half of its lower border; foot small, projecting but little beyond the abdominal mass; tubes long, distinct or united. There are 18 species of *Lutraria* found in the United States, Brazil, the Mediterranean, Senegal, Cape of Good Hope, India, New Zealand, Sitka, and the British Islands. There are 40 species of *Psammobia*. They are found in Norway, the British Islands, New Zealand, and the Pacific. *P. gari* is eaten in the Pacific.

(6679) *Soletellina.*—Shell oval oblong, compressed, with sharp edges, both curved; equivalve, subequilateral, much more wide and rounded at the cephalic extremity than at the other, which is more or less attenuated and sub-carinated.

(6680) *S. radiata* (*Solen rostratus*, Lam.). Shell transversely oblong, violaceous, with many obscure rays; anterior side attenuated and rostrated. It is found in Oriental seas.—*Eng. Cyc.*

(6681) PYRETHRUM (from πῦρ, fire, because of the hot taste of the root), a genus of Composite Plants belonging to the tribe *Asteraceæ*. It has a hemispherical involucre, the receptacle flat or convex. The fruit angular and not winged. The pappus an elevated membranous border.—*Eng. Cyc.*

(6682) PYRETHRUM, ANACYCLUS (*Anthemis*, *Linn.*) Pyrethrum, *Dec.* Pellitory of Spain.

Akerkurra, HIND. | Akerakarm, TEL. TAN

This root was known to Dioscorides (πυρεθρον), and is still employed in Eastern medicine by the name *akarkarha*. The plant is a native of the north of Africa, whence it has been introduced into the south of Europe. Hayne believes that the root is yielded by a nearly allied species, which he calls *A. officinarum*, ix. t. 46, and which he found cultivated in Thuringia.

Anacyclus Pyrethrum has a long fusiform root. Stems numerous, procumbent, branched, pubescent. Radical leaves spreading, petiolated, rather smooth, pinnatifid; the segments pinnated, with linear tubulate lobes; stem leaves sessile. Branches one-headed. Heads many-flowered. Involucre in few rows short, somewhat cup-shaped, scales lanceolate, pointed, brown at the edges. Receptacle convex, with oblong, obovate, obtuse paleæ. Florets of the ray female, sterile, white above and purplish beneath; of the disk, yellow, tubular, with 5 callous teeth. All the corols with an obcompressed, 2-winged tube without appendages. Style of the disk with exappendiculate branches. Achænium flat, obcompressed bordered with broad entire wings. Pappus short, irregular, tooth letted, somewhat continuous with the wings on the inner side. *Dec.*—Desf. Fl. A tl. ii. 287. Nees and Eberm. 244. St. and Ch. iii 97.

The root, as described by Desfontaines, in its fresh state is fusiform and fleshy, about the thickness of the finger, brownish-coloured externally and white within. When handled in this state, it produces first a sensation of cold, soon followed by heat. It is without odour, but has an acrid pungent taste, and causes a copious flow of saliva. It is said to be imported from the Levant. The French obtain it from Africa. It is cultivated in Thuringia and at Magdebourg. The active principle is soluble both in Alcohol and Ether, and appears to be a Volatile Oil, which adheres with tenacity to its Resin (*Pyrethrin*) and Fixed Oil. It also contains Inulin, Gum, a little Tannin, Colouring matter, various Salts, and Ligneous fibre. *Uses.* Irritant, Sialogogue. Sometimes used to relieve Toothache, or as a Masticatory in palsy of the Tongue and relaxation of the Uvula.—*Royle.*

(6683) PYRETHRUM INDICUM. FEVERFEW. Feverfew a gaudy flowered annual, usually denominated a Chrysanthemum, but which the botanists have removed to another genus, is often seen in gardens in Maulmain.—*Mason.*

(6684) PYRITES, FERRI SULPHURETUM. Sulphuret of Iron. Iron Pyrites.

Sulfure de Fer, FR. | Schwefeleisen, GER.

Iron combines with Sulphur in several proportions. It is common in the form of the

Bisulphuret, of a yellowish colour; hence has been thought to contain Copper. It was no doubt known to the ancients. *Prop.* The natural Bisulphuret ($Fe\ S_2 = 60$) or Iron Pyrites, called also Mundic, is of a colour like Brass, in hard cubical crystals, which are not acted upon by any of the acids, except the Nitric. Sp. Gr. 4·98. Often heated for the separation of the Sulphur by sublimation. If moistened and exposed to the air, Oxygen is absorbed, and the Sulphuret converted into Protosulphate of Iron. —*Royle.* Very abundant in the schistose rocks of Cuddapah, where it is manufactured into Sulphur.—*Ed.* Iron pyrites are very abundant in the Tenasserim Provinces. In some places they contain arsenic, and constitute arsenical sulphuret of Iron. The Burmese names though usually applied to iron, are generic, and might be applied to any pyrites.—*Mason.*

(6685) PYROLA. Herb of Chimaphila umbellata.—*Ben. Phar.*

(6686) PYROLIGNEOUS ACID, Acidum Pyroligneum, E. "Diluted Acetic Acid, obtained by the destructive distillation of Wood." Pyroligneous Acid is considered to be a discovery of Glauber; but it is probable, as stated by Berzelius, that it was known to the Egyptians, as may be inferred from a passage of Pliny, in which Pine wood, heated in a furnace, gives out "sudore, aquæ modo, fluit canali; hoc in Syria *cedrum* vocatur, ac tanta est vis, ut in Ægypto, corpora hominum defunctorum, eo perfusa, serventur." In the present day the distillation is usually conducted in iron cylinders, with condensers attached. The woody matter being decomposed by heat, its elements unite to form fresh compounds, and by distillation an acid liquor passes over with water, tarry matter, Empyreumatic Oil, and much inflammable gas, while a large proportion of excellent Charcoal is left in the retort. The Pyroligneous Acid is a brown, transparent liquid, consists essentially of Acetic Acid, diluted with water, holding in solution tar, with some Empyreumatic Oil, and has a smoky smell. It is distilled, and further purified, by the addition of Carbonate, of Soda. This is retained as Acetate of Soda (*v.* p. 100), or used for making a purer Acetic or Pyroligneous Acid. When the acetate of the above Alkali is formed, it is purified by crystallization and re-solution, afterwards decomposed with Sul. Acid the Acetic set free is again distilled, and the processes repeated until a nearly colourless acid, with the odour of the Acetic, is produced, but which is often Empyreumatic. Nearly or entirely colourless; Sp. Gr. at least 1.034; M. C. neutralize at least grs. liij. of Carb. of Soda; unaffected by Sulphuretted Hydrogen or sol. of Nitrate of Baryta.—*Royle.*

(6687) PYROLIGNEOUS ACID, is made from Cocoanut Shell in India.

(6688) PYROPE. Pali. A variety of the garnet, either identical or nearly resembling the pyrope garnet, is brought from Burmah. It is characterized by giving to transmitted light a yellow tinge, or as the natives say, the colour of the ox's gall; and hence the Burmese name, which in Pali signifies ox-gall.—*Mason.*

(6689) PYRUS, the Latin word for Pear-Tree, is the name of a genus of plants belonging to the natural order *Rosaceæ*. This genus is characterised by having a superior calyx with a 5-lobed limb; roundish petals; five styles; the fruit a closed 5-celled pome with a cartilaginous putamen called the core; two seeds in each cell; the testa cartilaginous. The species are trees or shrubs with simple or pinnate leaves, and the flowers placed on terminal many-flowered cymes. The species of this genus have obtained various names, as apples and pears, Crabs, Beam-Trees, and mountain-Ashes.

(6690) PYRUS AUCUPARIA, the Rowan-Tree, or Roan-Tree, known also under the names of the Fowler's Service-Tree and Mountain-Ash. Its Latin name, *P. aucuparia*, and its various modern designations, have been given to it on account of the general use made of its fruit for the purpose of decoying birds into traps. It is much cultivated, both on account of its valuable wood and rapid growth. It is known from the other species of *Pyrus* by its slightly glabrous serrated leaflets and its globose fruit. It is found in most parts of Europe, in the north-west of Asia, in Nova Scotia, and other regions of the northern parts of North America, and in the island of Japan. It does not however attain equal magnitude in all climates. In its most northern localities and alpine situations it is a low shrubby bush; whilst in southern districts it forms a handsome tree, growing to the height of 20 or 30 feet. The finest trees in Britain are found in the Western Highlands and on the west coast of Scotland. This tree has enjoyed from remote times a distinguished reputation. A belief in its power against witchcraft and evil spirits of all kinds seems to have been prevalent at a very early date; and, according to Lightfoot, in his 'Flora Scotica,' it was till a late period held in high reputation in Scotland as a charm against evil influence. It is through a hoop of this wood that sheep are made to pass night and morning as a preservative against evil spirits. The Rowan-Tree is a graceful tree, with an erect stem and orbicular head. It grows very rapidly for the first three or four years of its existence, and on this account it is well adapted for planting with young oaks, which it protects till they grow above it, when it is destroyed by their shade. It also forms excellent coppice-wood, the shoots being adapted for poles and for making hoops. The bark is used by tanners. The leaves, when dried, have been sometimes used in the north of Europe as a substitute for

wheat in times of scarcity. It is prized next to yew for making the bow. In Wales it is as religiously planted in churchyards as the yew is in England.—*Eng. Cyc.*

(6691) PYRUS COMMUNIS.

Amrud, Hind.

The Pear, has ovate serrated leaves, glabrous on both surfaces, with umbellate peduncles. It is a native of Europe in woods and hedges. In its wild state it is thorny, but always unarmed when cultivated. It is the pear Tree of English orchards. It is easily distinguished from the apple-Tree by the shape of its fruit.—*Eng. Cyc.* The Pear tree is not common in the Deccan gardens though some trees are to be found having been brought chiefly from Bangalore; the fruit is of a tolerable large size but coarse and hard, which only renders it fit for baking and stews. The same kind of fruit is found in the upper provinces of Bengal.—*Riddell.*

(6692) PYRUS CYDONIA. Pomaceæ.

Behee, Hind.

The quince. This tree has probably been introduced from China or Bengal, and is now to be met with in many gardens. It grows like the apple. The fruit is plentiful at Sattara, and Dr. Riddell met with it at Poonah. In other parts of the Deccan he has seen the tree in blossom, but the fruit did not set,—perhaps for want of proper treatment.—*Riddell.*

(6693) PYRUS MALUS. Pomaceæ.

Seb or Seo, Duck.

Pyrus Malus, the Apple, has acute serrate ovate-acute leaves; flowers in a sessile umbel; the fruit globose, and the styles combined below. This is the Crab-Tree of English hedges when wild, or the Apple-Tree of their orchards. Other species of *Pyrus* besides the above yield edible fruits. On Mount Sinai grows a species called *P. Sinaeia*, whose fruits is hard, gritty, and austere, and whose leaves are gray with down; in Germany a similar kind, the *P. nivalis*, is by no means uncommon, with a considerable resemblance to the last; Siberia and Persia produce another, called *P. salicifolia*, with very narrow hoary leaves; and in the former country are found the Siberian Crab, *P. prunifolia*, and the Berry-fruited Crab, *P. baccata*, whose fruit is too small for ordinary consumption, but is often seen in the form of a sweetment. Besides these, the Chinese Crab, *P. spectabilis*, and also *P. coronaria*, are cultivated for their flowers.—*Eng Cyc.*

The two sorts of apples commonly found in most Native gardens in the Deccan, are said to have been first introduced from Persia. They are of a small description; one sweet and luscious, grows in bunches; the other, which is larger, has a rough taste, and is better adapted for tarts. They may be propagated by layers, suckers, and even cuttings. The young plant should never be allowed to throw out branches at less than two or three feet from the ground; all the buds beneath must be rubbed off. Never plant them closer than from nine to twelve feet to each other, and if there is sufficient ground, keep them separate from other trees, so that they can either be wintered or watered as required. Remove all suckers round the stem of the tree, or from the roots, [unless required for stocks,] then cut them clean off with a sharp knife. The trees may be opened immediately after the rains, if not in blossom. Pluck off all the leaves carefully, and beware, in so doing, that the blossom buds are not injured, which native gardeners in the careless manner of stripping the leaves, are very apt to do;—then prune the tree. As soon as the blossom appears set, put plenty of old rich manure to them, and water well every third day until the fruit is nearly ripe. If you continue watering after this, it makes the fruit mealy and insipid. When the fruit is all gathered, cease to water the trees, and as soon as the leaves turn brown and dry, which will be in the course of a month, then open the roots for two or three days, cover with manure again, and water well as before, when you may probably get a second crop in April or May.—*Riddell.*

(6694) PYRUS: Pear Tree. Wallich found a species of pear tree growing on limestone mountains, near the Irrawaddy; and it may exist in the Tenasserim Provinces, though Mr. Mason has never met with it.—*Mason.*

Q.

(6695) QUADRUMANA, Cuvier's name for his second order of Mammiferous Animals, an order which must be always viewed by the zoolgis with great interest, inasmuch as it contains those forms among which will be found the nearest approach—though the distance is still great—to Man.

The order *Primates* of Linnæus consisted of the genera *Homo*, *Simia*, *Lemur*, and *Vespertilio*.

(6696) QUAIL, Mr. Gould recognises the common Quail of India as distinct from the European Quail.—*Eligh.*

(6697) QUAKING GRASS. Briza.

(6698) QUAMOCLIT, a genus of climbing Plants of the natural family of *Convolvulaceæ*, chiefly found in the hot parts of America, but species are indigenous both in India and China. The genus is characterised by having a 5-leaved calyx. Corolla somewhat salver-shaped, plicate, and 5-lobed. Stamens, 5, inserted into the base of the corolla. Ovary 4-celled. Cells with single ovules. Style simple. Stigma capitate and bilobed. Capsule 4-celled, 4-valved. Seeds 4, erect. Climbing plants with the leaves alternate, cordate, entire, lobed, or pinnatifid; pedunicles axillary; one or many flowers of a red colour. *Q. vulgaris* is common in every part of India, and, being a beautiful plant, has been cultivated in England as a tender annual. The name of the genus has been taken from that of this species, which was *Ipomœa Quamoclit*, the latter name signifying Dwarf-Bean, because, though smaller, it resembles the kidney-bean in its habit.—*Eng. Cyc.*

(6699) QUAMOCLIT ALBA. PURE WHITE.—Common, easily grown from seed.—*Jaffrey.*

(6700) QUAMOCLIT PENNATUM. *Syn.* IPOMÆA QUAMOCLIT. Jasmine rouge. This beautiful little creeper which the French and Burmese call red jasmine, the English China creeper, and the botanists quamoclit or dwarf bean, is quite naturalized throughout the Tenasserim Provinces, the French name is both more descriptive and euphonious than either of the others.—*Mason.*

(6701) QUAMOCLIT PHŒNICEA. This is a very handsome climber with flowers crimson, tube long and slender; grows readily from seed.—*Jaffrey.*

(6702) QUAMOCLIT VULGARIS. INDIAN FORGET-ME-NOT.—Sometimes called the star creeper, from the shape of the flower which is of a deep rosy red.—*Jaffrey.*

(6703) QUARTZ, the Mineralogical name of numerous varieties of Rock Crystal, the Native Oxide of Silicon [SILICON], called also Siliceous or Flint Earth, and Silicic Acid. It is remarked by Mr. Brooke ('Mineralogy') that the "differences of structure, hardness, specific gravity, mixture with foreign matter, and other characters belonging to this species, are so numerous as to render any single description inapplicable to all its varieties." Some of the varieties of quartz have been already described; these we shall presently refer to. Quartz occurs crystallised and massive, and in both states it is widely diffused throughout nature, and is especially one of the constituents of granitic and the older rocks. In India, the finest specimens of crystallised quartz occur in Madura and at Vellum &c.; they are found in Cornwall and near Bristol of great brilliancy, and are known by the name of Cornish and Bristol diamonds. To enumerate the different places in which this substance occurs would be most endless. Quartz is composed of one equivalent of silicon = 14, and one equivalent of oxygen = 8; its equivalent is therefore 22.

Hornstone and *Chert* are varieties of compact quartz. Cavernous quartz is termed Spongiform Quartz or Swimming Stone, and other scarlet varieties have also been described.

Quartz possessing different colours has received various names; some of these we shall briefly notice.

Brown or Smoky Quartz occurs in fine crystals near Cairngorm in Aberdeenshire. It is used for seals and ornaments when cut and polished. The nature of the colouring-matter is not known, but is probably carbonaceous matter.

Purple Quartz or *Amethyst*, is found both crystallised and massive. It is of every shade of purplish-violet, and the colour in the perfect amethyst is pretty equal throughout the crystal or mass; frequently however the summits of the crystals only are coloured. It is used for ornaments. According to Rose, amethyst consists of—

Silica	97·50
Alumina	0·25
Oxide of Iron	0·75
	98·5

Amethysts of the first quality are found in India, Ceylon, Persia, and Siberia. Amethystine Quartz of inferior quality is met with in most countries. In Cornwall it occurs in some tin-mines.

Blue Quartz (*Siderite*) occurs crystallised and massive. It is compact, of a grayish or greenish-blue colour. Lustre resinous, waxy. Translucent on the edges. It is found near Salzburg.

Green Quartz is found in Peru, in translucent hexagonal prisms. Opaque massive green quartz is called Prase; the colour appears to be owing to actinolite. It is found in Saxony. *Chrysoprase* is light green amorphous quartz; it is coloured by oxide of nickel. It is found in Silesia and North America

Yellow Quartz is transparent; of various shades of colour. It is found in Cornwall, Scotland, Bohemia, &c. It is probably coloured by oxide of iron It has been called Scottish and Bohemian Topaz.

Yellow Quartz is opaque. Ferruginous Quartz occurs of various shades of yellow and reddish-yellow. According to Bucholz, it contains 5 per cent of oxide of iron, to which its colour is owing. It is found near Bristol, in Scotland, &c.

Red Quartz (*Compostella*), Hyacinthine Quartz. Colour yellowish or reddish-brown. It is found in Spain and North America.

Amorphous Quartz. The following are varieties of quartz: AGATE, AVANTURINE, FLINT, FLINTY SLATE, OPAL, and BLOODSTONE.

In addition to these, which may be considered among the purer varieties of quartz, it occurs

mixed with variously-coloured clays and other extraneous matter, forming different kinds of Jasper. *Jasper* occurs opaque, which constitutes one of the most prominent differences between it and agate. Its colours are green, yellow, and red, of various shades, rarely blue: these colours are occasionally mixed in spots and irregular veins. Jasper is massive, has often a resinous lustre, but is sometimes dull. It is found on many parts of the continent, in Cornwall, and in Scotland. Striped or Riband Jasper presents green, yellow, and red colours of various shades, sometimes in spots; but the most beautiful variety is composed of equal and parallel stripes of these colours. It occurs in Siberia, the Hasz, and Saxony. Egyptian Jasper, or Egyptian Pebble, occurs in rough roundish masses, and is generally of a brown colour. Internally it is usually of a light colour. It is found on the surface to the eastward of Grand Cairo, and on the borders of the Red Sea. It is well known that siliceous earth assumes other forms besides that of quartz and the varieties of it which have now been described: one of the most useful of these is Common Sand.—*Eng. Cyc.* According to Tomlinson, quartz is the mineralogical name of a substance widely diffused throughout nature, as in the numerous varieties of rock crystal or native oxide of silicium, siliceous or flint earth, and silicic acid. Quartz is one of the constituents of granite and of the older rocks. It also occurs crystalized and massive. The primary form of the crystal is a rhomboid, but it is generally found in hexagonal prisms terminated by hexagonal pyramids, and when the prism is wanting and both pyramids are present, the crystal is a dodecahedron with triangular planes The cleavage is not usually traceable by ordinary means, but may often be detected by heating the crystal and plunging it in water. The cleavage is parallel to the planes and pyramids of the ordinary crystal. The fracture is conchoidal, hardness 7.0; it scratches glass readily, and gives fire when struck with steel. It becomes positively electrical when rubbed, and two pieces when rubbed together in the dark become luminous. It is transparent, translucent or opaque; the lustre is vitreous or resinous: the specific gravity 2.69 to 2.81. It is infusible, insoluble in most acids; but it combines with the fixed alkalies and produces silicates.

Pure quartz is colourless, but quartz usually exhibits a great variety of colours. Purple quartz or *amethyst* occurs both crystallized and massive: it is of every shade of purplish violet: it contains alumina and oxide of manganese. Magnificent crystals of this occur in the Hyderabad territory and in Central India. *Blue* quartz or *siderite* also occurs crystallized and massive. The *Cairngorm* or *smoky quartz* contains a small quantity of bitumen. *Green* quartz is found in Peru in translucent hexagonal prisms. Opaque massive green quartz is called *prase*: it is found in Saxony. *Chrysoprase* is an amorphous quartz of a light green colour, oxide of nickel being the colouring matter. *Yellow* quartz, called *Scotch*, and *Bohemian topaz* is of various shades of yellow. *Opaque yellow* or ferruginous quartz contains about 5 per cent. of oxide of iron: it occurs in various shades of yellow and reddish yellow. *Red* quartz, or *Compostella hyacinthine* quartz, is of a yellowish or reddish-brown.—*Tomlinson.*

(6704) QUASSIA.

Bois de quassie, Fr. | Leno de Quasia, Sr.
Quassienholz, Ger. |

An intensely bitter wood, obtained from the *Q. Excelsa* of Jamaica, which furnishes the greater part of the chips sold as quassia by European druggists. The *Q. Amara* is a native of Surian, Guiana, Colombia, Panama, and has been recently introduced into Bengal. Quassia wood is a very pure and simple bitter, and has been much employed in bilious and intermittent fevers, gout, &c. It is also supposed to be used by some brewers as a substitute for hops, although forbidden by law.—*Faulkner.*

(6705) QUASSIA AMARA. Bitter quassia. The wood.

This native of Surinam, Guiana, Colombia, and Panama, was introduced into Bengal by Lord Auckland. It thrives tolerably well in the Calcutta Garden. *Med. uses.* Quassia wood is a very pure and simple bitter, and has been much employed in bilious and intermittent fevers, dropsies from debility, atonic gout, and indeed in all cases in which bitter tonics are advisable. The English brewers use it freely as a substitute for hops, although it is thought to have some degree of narcotic power, a decoction of quassia being much used as a poison for flies. Quassia is with much difficulty reduced to powder, and is consequently given in the forms of extract, tincture, infusion, and decoction. —*O'Shaughnessy, page* 267.

(6706) QUASSIA SIMARUBA. Bitter, or mountain damson. *Syn.* Simaruba amara, *Lindley. Off.* The bark.—*Ibid* 267.

(6707) QUERCITRON, the bark of the *quercus nigra*, or *tinctoria*, or yellow oak, a native of North America. It is prepared for use by taking off the epidermis and pounding the inner bark in a mill. Its colouring principle, *quercitrine*, forms pale yellow spangles; it has a faint acid reaction, is soluble in alcohol, and to a certain extent in water. A decoction of the bark, deprived of its tannine by means of glue, produces a fine yellow upon fabrics mordanted with alum, and various shades of olive with iron mordants. It is much used in calico-printing.—*Tomlinson.* Quercitron bark is an important yellow dye, obtained from the bark

of a species of oak (*Quercus tinctoria*, or *nigra*), indigenous to North America.—*Faulkner.*

(6708) QUERCUS; OAK.

Baalut, Arab.	Quercus, Lat.
Eeg, Dan.	Dab. Pol.
Eik, Dut.	Roble, Carbalho, Port.
Chene, Fr.	Dub, Rus.
Eiche, Ger.	Roble, Sp.
Quercia, It.	Ek, Sw.

A genus of well-known timber trees (*Quercus*), embracing about 150 species. *Quercus*, the Latin word for an oak-tree, which is of frequent occurr ence in the Roman writers. It is now, as then, applied to the oak and all the other species associated with it by botanists in one common genus. *Quercus* differs essentially from *Castanea*, the Chestnut, in having short obtuse stigmata, and from both it and *Fagus*, the Beech, in the cells of its ovary containing two ovules instead of four. It is also distinguished by its acorn or nut being seated in a cup, and not in a close husk; but there are intermediate conditions of this part, technically called the cupule, which render it of less value as a mark of distinction than would at first sight appear. Many of the oaks of the hotter parts of Asia have the acorn completely inclosed within the cupule. Still however the prickly husk of the beech and the chestnut, splitting into valves, may in general be distinguished from the closed-up cup of the Indian oaks. Oaks, like roses, are scarcely known in a wild state in the southern hemisphere. In the Islands of the Indian Archipelago they reach their most southern limits, especially in Java; thence they pass upwards beyond the equinoctial line, and following the eastern parts of Asia, they spread to the westward along the Himalaya Mountains, and reaching Europe, are only arrested by the Atlantic Ocean. On the other hand they find their way to the eastward of their Asiatic origin, and overrun America from Canada and Oregon through California and Mexico, till their progress to the south is stopped by the Isthmus of Darien. While however the genus is thus extensively distributed, the species are confined within comparatively narrow territorial limits. Many of the Javanese kinds appear to be peculiar to the Indian Archipelago, or only occur near the south-eastern angle of Asia. Those of the Himalayas are perfectly distinct from the oaks of the Trans-Himalayan regions, and have not even been found on the mountains of Persia. Several of the Oriental kinds are known nowhere else, and the American species are quite peculiar to that country. The species are very numerous, and we propose to give some of the more remarkable according to their geographical distribution.—*Eng. Cyc.* All travellers in the Himalayas testify to the abundance of oaks. The people employed by Dr. Wallich gathered a considerable number of species, and Dr. Royle assures us that they are found from moderate elevations up to t limits of trees. Among these, all from t lower regions are no doubt, too tender f cultivation in Great Britain; but of t alpine species some may be expected to pro hardy.—*Eng. Cyc.* Several species are ind genous in the Tenasserim provinces. Mason sa Wallich found seven different species of oa Quercus fenestrata, turbinata, velutina, Que cus Amherstianus and Tirbbœ, growing in Bu mah and on the Tenasserim Coast. Three four are natives of these Provinces, and all affor useful timber, though inferior to the Englis oak.—*Mason.* No oak nor chesnut ascend above 9000 feet in the interior of Sikkim, wher they are replaced by a species of hazel (Corylus) in the North Himalaya, on the other hand, a oak (*Quercus semecarpifolia*; see vol. i. p. 187 is amongst the most alpine trees, and the mu is a different species, more resembling th European. On the outer Sikkim ranges oak (Q. annulata?) ascend to 10,000 feet, and ther is no hazel.—*Hooker Him Jour. Vol.* II, *p.* 144 It is not generally known that oaks are often very tropical plants; not only abounding at low elevations in the mountains, but descending in abundance to the level of the sea. Though almost unknown in Ceylon, the Peninsula of India, tropical Africa, or South America, they abound in the hot valleys of the Eastern Himalaya, East Bengal, Malay Peninsula, and India islands; where perhaps more species grow than in any other part of the world. Such facts as this disturb our preconceived notions of the geographical distribution of the most familiar tribes of plants, and throw great doubt on the conclusion which fossil plants are supposed to indicate.—*Hooker Him. Jour. Vol.* II. *page* 436. Two fine species of evergreen oaks were observed by Fortune in the Himalayas named *Quercus dilatata* and *Q. semicarpifolia*. Amongst herbaceous plants he noticed some pretty primroses, *Lilium giganteum* and *Wallichianum*, and *Fritillaria polyphylla*. Here also was the once famous Prangos in full bloom.—*Fortune*, *p.* 366. He observed also two specimens of evergreen oak (*Quercus sclerophylla* and *Q. inversa*), with large and glossy leaves, not unlike the Portugal laurel at a distance. Dr. Wight gives in Icones, Quercus acuminata, 221; armata, 770; castanicarpa, 769; fenestrata, 219; ferruginea, 938; lanceaefolia, 212; [illegible] 930; semiserrata, 211; squamata, 213; turbinata, 224.

(6709) QUERCUS ANNULATA, Ring-Cupped Oak. Leaves obovate, taper-pointed, serrated in their upper half; somewhat glaucous and silky beneath. Acorns axillary, sessile, ovate, with the cup furrowed concentrically. Found in the Himalayas.—*Eng. Cyc.*

(6710) QUERCUS BALLOTA. Probably that described in Persian works as *Shah bulloot*

nd *Bulloot ul mulk.* Hamps. *Theophr.* A native f Spain and Greece. The acorns of *Q. incana* re sold in the bazars as a medicine, under the ame of *Bulloot.*—*O'Shaughnessy, page* 607. oxburgh says that a species of oak, *Quercus mestra*, is a native of the mountains in the icinity of Silhet; on the Tenasserim Coast the ame species grows indigenous not fifty feet above e level of the sea.—*Mason.*

(6711) QUERCUS CASTANEÆFOLIA, the hestnut-Leaved Oak. Leaves oblong-lanceote, rather downy on the under side, coarsely rrated, with bristle-pointed lobes. Acorns near- sessile, oblong, with the cups, when old, overed by reversed scales. A tree from the rovince of Mazanderan, reported to be very eautiful. The leaves are often from 4 to 5 ches long. Mr. Barker Webb states that it is e same as what has been called *Q. Libani*, and at it is remarkable for having large depressed uit, with wide lozenge-shaped scales turned ack at the point.—*Eng. Cyc.*

(6712) QUERCUS CHINENSIS, the Chi- se Oak. Leaves ovate-lanceolate, taper-point- l, with bristly shallow serratures, and very long footstalks; slightly downy on the under side. Acorns globose, sessile, in pairs. Cups with hoary lanceolate scales, the exterior of which are reflexed, and longer than the acorn. A beautiful Chinese species, found (by the botanists attached to the Russian mission to Peking) in mountainous places. It is said to have exactly the habit and appearance of a Spanish chestnut. A figure of it has been given from specimens communicated by Dr. Bunge, its discoverer.—*Eng. Cyc.*

(6713) QUERCUS FAGINEA, Beech-Oak. Leaves on short stalks, obvate, with numerous uniform shallow lobes; downy beneath; when young somewhat heart-shaped and unequal at the base. Fruit sessile. Cup with downy close-pressed somewhat ciliated scales. Acorn conical or somewhat cylindrical. A native of Portugal, Spain, and Tangiers, and apparently unknown in our gardens. Mr. Barker Webb however, who has studied some of the European species with great care, regards it as identical with *Q. Turneri*, or *Q. Australis*, and if so, we possess it. The same learned botanist reduces to this the Aleppo Gall-Nut Oak, *Q. infectoria*, and he is probably right.—*Eng. Cyc.*

(6714) QUERCUS INCANA, the Himalayan Ilex. Leaves coriaceous, ovate-lanceolate shining and smooth on the upper side, densely downy beneath, with coarse serratures which are not bristle-pointed. Acorns solitary, sessile, acute, but little protruded beyond the hemispherical downy cup, the scales of which are small and closely pressed. A beautiful tree, very like the evergreen oak of Europe. Its leaves are much more woolly on the under side. Dr. Wallich found it in Kumaon, where the people called it 'Munroo;' Dr. Royle states it to be the 'Ban' of the hill people, where he saw it, and that it occurs at moderate elevations. It is therefore in all probability tender.—*Eng. Cyc.*

(6715) QUERCUS INFECTORIA, Gall-nut oak. Galls.

Majoophul, Hind.

Asia Minor, Armenia, and Kurdistan, a shrub 4 to 6 feet high. This tree when punctured by a *cyneps* allows an astringent juice to exude, which becomes the *gall nuts* of commerce.—*O'Shaughnessy, page* 608.

(6716) QUERCUS INFECTORIA, Oriental Gall-Oak. Leaves ovate-oblong, very smooth on both sides, deeply toothed, somewhat sinuated deciduous. Fruit sessile. Cup tesselated. Acorn elongated, nearly cylindrical. A very common plant in Asia Minor, where its branches are attacked by an insect, the *Cynips scriptorum*, which punctures them, and causes the formation of the oak-galls so well known in commerce. It forms a scrubby bush rather than tree, and is of no value except for its galls. Its branches occasionally produce large brownish-red tubercles, spongy within, which are by some supposed to be the apples of the Dead Sea, whose appearance was tempting, but which contained only dust and ashes.—*Eng. Cyc.*

(6717) QUERCUS LANATA, woolly-Leaved Nepaul Oak. Leaves elliptic-oblong, deep green, sharply serrated, coriaceous; densely woolly beneath. Fruit in very short axillary solitary spikes. Cup scaly, without prickles. This is one of the handsomest oaks yet discovered. It is found wild in the Himalayas.—*Eng. Cyc.*

(6718) QUERCUS MANNIFERA, the Manna Oak. Leaves stalked, oblong, somewhat heart-shaped, cut; the lobes blunt, smooth above, downy beneath. Young acorns oval, stalkless, smooth. An inhabitant of the Kurd Mountains, where it was discovered by Mr. Brant, the British consul at Erzerum, who found that the Kurds obtain a sweet mucilaginous substance from its branches and leaves by steeping them in boiling water at the hottest season of the year, and afterwards evaporating the water. This substance is made into cakes, and sold in the markets of the town of Van under the name of Ghiok-Helvashee, 'the Sweetmeat of Heaven.' The species is very near *Q. sessiliflora*, especially a form of it which has been named *Q. Monghol-lica.*—*Eng. Cyc.*

(6719) QUERCUS PEDUNCULATA: its bark is used in Medecine.—*Ben. Ph.* 217.

(6720) QUERCUS REGIA, the Royal Oak. Leaves stalked, ovate-lanceolate, heart-shaped, wavy, with coarse sharp unequal serratures, on each side green, shining, and smooth. The lobes of the leaves terminated by a conspicuous bristle. From Kurdistan. It is a noble species, with leaves as large as those of a Spanish chestnut, and very like them.—*Eng. Cyc.*

(6721) QUERCUS RIGIDA, Stiff-Leaved Oak. Leaves oblong, undivided, with spinous serratures, smooth, glaucous beneath, heart-shaped at the base. Footstalks bearded at the summit. Scales of the cup rigid, spreading. A native of Caramania, of Kurdistan, and, according to Sibthorpe, of the Morea, but the last is doubtful. It is a handsome-looking plant, so far as can be judged from dried specimens, but nothing is known of its uses.—*Eng. Cyc.*

(6722) QUERCUS SEMICARPIFOLIA, Marking-Nut-Leaved Oak. Khasrou of the Nepalese, is found in East Nepal, is common as far-west as Cashmere. It is not found in Sikkim, though it appears again in Bhotan. It ascends in the Himalaya to 12,000 feet, which is the highest limit of forest: but in Sikkim no oak attains a greater elevation than 0,000 feet.—*Hooker, Him. Jour. Vol* I *p.* 187. The quercus semicarpifolia, has Leaves obovate, obtuse, coriaceous, entire; heart-shaped at the base; downy beneath; the young ones with spinous teeth. Acorns solitary or in pairs, on short downy stalks, depressed at the point, about twice as long as the shallow scaly cups. As this species occurs in the Himalayas at the upper limits of the forests, at even greater elevations than the Pines, it would, no doubt, suit the climate of England; and if so, its introduction would be very desirable, for it is stated to form a magnificent tree, whose timber is much esteemed by the natives.—*Eng. Cyc.*

(6723) QUERCUS SERRATA. AMENTACEÆ.

Shingra, Duc.

These trees are only found in the hill stations, where they have been grown from seed by private individuals. At Mahabuleshwar, a few plants have been grown, more resembling a shrub than a tree.—*Riddell.*

(6724) QUERCUS SUBER Cork-Tree. Leaves ovate-oblong, bluntish, coriaceous, entire or sharply serrated, downy beneath. Bark cracked, fungous. The Cork-Tree is spread through all the warm parts of Spain, but is most abundant in Catalonia and Valencia, whence the principal exports have been made. In the property of forming a spongy soft substance on its bark, it surpasses all other European trees, and hence is of the greatest value for corks and for similar purposes. The form of the tree is said to be much more beautiful than that of the common evergreen oak, and in the districts suited to it, attains a great height. The species bears the climate of London, but acquires little of its natural beauty in that country.—*Eng. Cyc.*

(6725) QUICK LIME.

Ahuk, ARAB.	Capoor, MAL.
Hunnoo, CYNG.	Nurch, PERS.
Chaux, FR.	Iswet, RUS.
Walk, GER.	Churna, SANS.
Chunam, Chuna, GUZ. HIND.	Cal, SP.
Calcina, Calce, IT.	Chunamboo, TAM.
Calcium, LAT.	Sunnam, TEL.

The common method of obtaining quick lime is by the process of burning, in which limestone mixed with wood, coal, or charcoal, is exposed to a strong heat; in this way the carbonic acid is expelled, and the product called *quick-lime* is the result. It is white, of a pale gray tint, opaque, inodorous, and its taste acrid and alkaline. When water is poured upon quick lime it heats, crackles, swells, and a bulky white powder is obtained, called *slaked lime*. Lime is used as a manure, and as an ingredient in mortar. In several metallurgic processes, it is used as a cheap and powerful flux; it is also extensively employed in soap making, leather dressing, dyeing, and medicine, besides many other purposes in common life and the arts. In oriental commerce, the term *Chunam* is applied to quick lime made from calcined shells.—*Faulkner.*

(6726) QUILLS.

Plumes á ecrire, FR.	Penne de serivre, IT.
Posen, Feder kiel, GER.	Stivoli. RUS.
Kulm, Guz HIND.	Canones para escribir, SP.

The hard and strong feathers of the wings of geese, ostriches, turkeys, &c. used in writing.—*Faulkner.*

(6727) QUINCE. PYRUS CYDONIA.

(6728) QUINCE SEED.

Behdana, Hub-ul-suffurgul, ARAB.	Behdana Guz. HIND.
Semen de Coig.	Melacotogna, IT.
Quincunx, FR.	Behdana, PERS.
Quittenkorner, GER.	Behdana, TAM.

Are oval, acute seeds, plain at one side, convex at the other, often triangular, truncated at one end, of iron colour externally, and internally white. They abound in mucilage, and are an article of the materia medica. This seed constitutes an important article of commerce in India, being highly valued as a demulcent tonic, and restorative remedy by the Hindoos and Mahomedans all over the East. They are imported into Bombay and Calcutta from the Persian Gulf; and into Northern India they are brought from Cabul and Cashmere.—*Faulkner.*

(6729) QUININE, a vegeto-alkali obtained from yellow bark, as *cinchonia* is from pale bark. [See BARK.] The valuable medicinal properties of the Peruvian barks are due to these vegeto-alkalis. They are associated in the bark with sulphuric and *kinic* acids. Pale bark, or *cinchona condaminea*, contains most cinchona; and yellow bark, or *C. cordifolia*, most quinia. Both are contained in *C. oblongifolia*. There are various methods of preparing cinchonia and quinia. The simplest is to add a slight excess of hydrate of lime to a strong decoction of the ground bark in acidulated water; to wash the precipitate and

boil it in alcohol. The solution filtered while hot deposits vegeto-alkali on cooling. When both bases are present they may be separated by converting them into sulphates, the salt of quinia being the less soluble of the two crystallizes first and may be separated. Cinchonia $C_{20} H_{12} NO$, crystallizes in small, brilliant, transparent, four-sided prisms. It dissolves slightly in water, but readily in boiling alcohol; it has little taste, although its salts are excessively bitter. It acts as a powerful base, completely neutralizing acids and forming crystallizable salts. Quinia or quinine $C_{20} H_{12} NO_2$, resembles cinchonia in many particulars: but it does not crystallize so readily: it is more soluble in water and its taste is intensely bitter. Sulphate of quinine, as mentioned under BARK, is largely manufactured for medicinal use: it crystallizes in small white needles, and its solubility is increased by the addition of a small quantity of sulphuric acid. The refuse or mother liquor of the quinine manufacturers contains *amorphous quinine*, also called *chinoidine* or *quinoidine*. It is a yellow, or brown resinlike mass, insoluble in water, but freely soluble in alcohol and ether, as also in dilute acids. It is said to be indentical in composition with quinine; if so, it may bear to quinine the same relation that uncrystallizable syrup does to ordinary sugar, it being produced from Quinine by the heat employed in the preparation.—*Tomlinson.*

(6730) QUISQUALIS, a genus of Plants of the natural family of *Combretaceæ*, which is indigenous in Amboyna, Java, and the Malayan peninsula, and extends into India. The genus is characterised by having a very long slender tube of the calyx, which is 5-fid at the mouth. Petals 5, oval, oblong, larger than the teeth of the calyx. Stamens 10, inserted into the faux of the calyx; the alternate ones shorter. Ovary ovate, oblong, 4-valved Style filiform, obtuse. Drupe dry, 5-angled, 1-seeded. Shrubs with climbing branches. Leaves opposite, seldom alternate, entire, ovate. Spikes axillary and terminal. Flowers change in colour from white to red. The few plants of the genus are cultivated in England with great ease in moist stove-houses in a mixture of loam and peat.—*Eng. Cyc. Quisqualis Indica* is the most common species; its fruit is reckoned a vermifuge.

(6731) QUISQUALIS INDICA.—The Chinese Honey Suckle or Rangoon Creeper. A scandent shrub, with beautiful flowers of various colours, from white to orange and deep red; has a very powerful perfume towards night. It grows from layers, or seed, but the latter are very difficult to find.—*Jaffrey.* In Tenasserim, this elegant scandent shrub is seen trailing its long arms around our bowers and verandahs, buried in thick lively foliage, and gracefully flinging out its thousands of sweet-scented flowers which change their tint from white to rose, and with the clouds at sunset, deepen into richest crimson.—*Mason.* The flowers are scarlet outside and yellowish white within, and hang in large clusters, very useful in covering walls or trellis work, the scent at night is unpleasant to some persons. It is a very common plant in the gardens of the Deccan and may be raised from seed or layers.—*Riddell.*

(6732) QUITCH. [TRITICUM; AGROSTIS.]

R.

(6733) RADISH, RAPHANUS SATIVUS. Radicula, and oblongn. Lin.

Mooliughie, TAM.	Moolaka, SANS.
Mara, GUZ.	Labak, MALAY.
Moollie, HIND. and DUK.	

Used in salads, the seed pods when young make excellent pickles, raised from seed sown thinly on beds broad cast; require rain water. The red, white, pink and purple turnip varieties succeed best on the plains, the black spanish *R. niger* is of little value, used in salads.—*Jaffrey.* This vegetable may be sown at the commencement of the rains, either in beds broadcast, or on ridges of beds where other vegetables have been planted, prefer the ridges in the rainy season, as there they grow better. You may continue to sow them until February. The turnip-radishes are of various colours—white, red, spanish black, and purple: also long white, red, and purple. The seed should be trodden in, or beaten down, and then a good watering given to them. When about three inches high, they must be carefully thinned, leaving at least a space of five fingers' breadth between each plant. They take from three to five weeks to come to perfection, and require a good share of watering. The seed pods are often used for pickles when green—*Riddell.*

(6734) RADISH SEED OIL, from Raphanus sativus, was exhibited at the Madras Exhibition of 1855.—*M.E.J.R.*

(6735) RAGGEE. ELEUSINE CORACANA.

Ragooloo, TEL.	Ragee, HIND.
Kazh varkoo, TAM.	

(6736) RAGEU. Dr. Hooker's dogs caught a "Rageu," at Choongtam. It is a very remarkable animal, half goat and half deer; the flesh

was good and tender, dark-coloured, and lean. It is the "Ragoah," according to Hodgson; but it is not the *Procapra picticaudata* of Tibet.—*Hooker Him. Jour. Vol.* II. *page* 98.

(6737) RAGS.

Lompen, Dut.	Chiffes, Drapeaux, Drilles, Fr.
Lumpen, Ger.	Chendee, Guz. Hind.
Stracci, Strazze, It.	Farropos, Trapos, Port.
Trebje. Rus.	Trapos, Andrajos, Sp.

Shreds or fragments of old linen, woollen, or cotton cloth. They are of great importance in the arts, being used for various purposes, especially in the manufacture of paper, the greater portion of which is entirely prepared from rags. Rags are sometimes exported from Bombay to London and Liverpool.—*Faulkner.*

(6738) RAFFLESIA. The name of a genus of plants found in the hot damp jungle of Sumatra, growing parasitically on a kind of vine, and discovered by the late Sir T. S Raffles, whose name it bears. It consists of a number of scales investing a fleshy calyx measuring a yard in diameter and containing the organs of fructification within or beneath the rim of a huge fleshy central column. [Rafflesiageæ.]—*Eng. Cyc.*

(6739) RAFFLESIACEÆ, *Patma-Worts*, a natural order of stemless leafless Parasitical Plants, consisting of flowers growing immediately from the surface of branches, and immersed among scales. The perianth is superior, with a 5-parted limp, thickened processes or calli either distinct or united into a ring being attached to the throat of the tube. The essential organs are combined in a column which adheres to the tube of the perianth. Anthers 2-celled, either distinct and opening by vertical apertures, or combined together so as to become a multicellular mass opening by a common pore. Ovary 1-celled; placentas, parietal. Fruit indehiscent. The species are East Indian and South American plants, parasitic on the species of *Cissus* and on some *Leguminosæ*. There are 16 species. Some of them are said to be styptic. Their perianth has a fungoid appearance —*Eng. Cyc.*

(6740) RAFFLESIA ARNOLDI, a Sumatra parasite, is capable of containing 12 pints of fluid in its cup. The flower is said sometimes to have a weight of 14 lbs.—*Eng. Cyc.*

(9741) RAFFLESIA PATMA is employed as an astringent and styptic in Java. *R. Horsfieldi*, *R. Cumingi*, and *R. Rochussenii* have similar properties. The genera are *Rafflesia*, *Sapria*, *Brugmansia*, *Apodanthes*, and *Pilostyles*. (Balfour, *Class-book of Botany*; Lindley, *Vegetable Kingdom.*)

(6742) RAIANIA, a genus of Plants so-called in honour of the great naturalist John Ray, is known by the staminiferous flowers having a bell-shaped perianth in six deep oblong pointed segments, most spreading in their upper part.—*Eng. Cyc.*

(6743) RAIANIA HEXAPHYLLA. Six-Leaved Clustered Raiania. Leaves six, on a common stalk, oblong-acute. Flowers racemose. It is a native of the country of Fakonia, in Japan, among bushes, flowering in April. The stem is round, striated, smooth, climbing. The flowers in axillary racemes, clusters snow-white. It differs from *R. quinata* in having mostly six leaflets on a stalk, which are acute, reticulated, with veins at the back, and larger than in that species. The flowers moreover grow in clusters, not in umbels.—*Eng. Cyc.*

(6744) RAIANIA QUINATA, Five-Leaved Umbellate Raiania, has five leaves on a common stalk. It was observed by Thunberg about Nagasaki, and in Japan, flowering in April and May. The stem is twining, round, smooth, ash-coloured, and branched. Leaves several together, axillary, stalked, smooth. Flowers in umbels from the same buds as the leaves, on slender stalks, as long as the footstalks.

(6745) RAIIDÆ or RAINÆ, a sub-order, or family of Plagiostomous Cartilaginous Fishes, of which the Common Ray is the type. The body of these fishes is horizontally flattened, and more or less discous; the dorsal fins are mostly placed on the tail; a peculiar cartilage, called naso-pectoral, arises from the nasal part of the skull, and extends towards or meets the anterior part of the crest or pectoral fin; the branchial openings are inferior.—*Eng. Cyc.*

(6746) RAIKH-MAI. A fish (sort of eel) found in the sand of rivers, imported dried via Delhie: considered aphrodisiac.—*Irvine p.* 150.

(6747) RAIN. The climate of Khasia is remarable for the excessive rain-fall. Attention was first drawn to this by Mr. Yule, who stated, that in the month of August, 1841, 264 inches fell, or twenty-two feet, and that during five successive days, thirty inches fell in every twenty-fuur hours! Dr. Thomson and Dr. Hooker also recorded thirty inches in one day and night, and during the seven months of his stay, upwards of 500 inches fell, so that the total annual fall perhaps greatly exceeded 600 inches, or fifty feet, which has been registered in succeeding years! From April, 1849, to April, 1850, 502 inches (forty-two feet) fell. This unparallelled amount is attributable to the abruptness of the mountains which face the Bay of Bengal from which they are separated by 200 miles of Jheels and Sunderbunds.—*Hooker. Him. Jour. Vol.* II. *page* 282.

(6748) RAISINS.

Raisins secs ou passes, Fr.	Uve Passe, It.
Rosinen, Ger.	Passas, Port.
Darakh, Mowage, Guz and Hind.	Issum, Rus.
	Pasas, Sp.

Are dried grapes. They are distinguished by the places where produced or exported, as Malaga, Valencia, Persian, Smyrna, &c; or from the variety of grape or mode of preparation, as, muscatels, blooms, sultanas, &c.—*Waterton.* Raisins, (Monukka: Kishmis: Bedana,) N. W.

India, from Istaulik, &c. Vitis vinifera.—*Ben. Phar.* 222. In the south of Europe and in Egypt, &c. grapes are allowed to ripen and dry upon the vine so as to form raisins. The sweet fleshy grapes which grow upon the sunny sheltered slopes of hills are preferred. When the fruit is ripe, the grapes are thinned and the vine is stripped of its leaves. The sun then completes the saccharifications and drives off the superfluous water. When the bunches are plucked they are cleaned, dipped for a few seconds in a boiling lye of wood-ashes and quicklime; the wrinkled fruit is then drained and dried, exposed to the sun upon hurdles for 14 or 15 days. The finest *sun* raisins are the plumpest bunches left fully to ripen upon the vine, after their stalks have been cut half through. An inferior kind of raisins is prepared by drying the grapes in an oven. In the year ending 5th January 1853, 261,824 cwt. of raisins were imported into the United Kingdom, of which quantity 208,801 cwt. were retained for home consumption. The import duty is 15*s.* per cwt. from foreign countries, and 7*s.* 6*d.* per cwt. from British possessions.

(6749) RALLIDÆ, a family of Birds belonging to the *Grallæ* of Linnæus, *Grallatores* of Illiger. The species are commonly called Rails. The species are numerous in South America; some in India; and a few in Africa.

(6750) *Porphyrio.*—Bill short, strong, high; the base dilated into a flat plate on the front of the head; the culmen arched. Nostrils large, basal, covered by a membrane, naked; the aperture terminal and oval. Feet very large. Toes without any lateral membrane. Claws large, slightly curved. (Sw.) There was a quality which was supposed to reside in the *Porphyrio*, which made it both a highly prized and dangerous inmate. The bird was considered as a kind of guard over the women of the house in which it was domiciled: it was believed that it took notice of adultery, and that if the crime was committed, it would give notice to the master of the house by making signs as if it wished to strangle itself. It is to this that the old quatrain alludes in the 'Portraits d'Oyseaux':—

> "Porphyrion declare l'adultere.
> Fait au logis auquel on l'entretient:
> Car a ces fins tous les semblans ils tient
> De se vouloir estrangier et deffaire."—*Eng. Cyc.*

(6751) *Porphyrio Hyacinthinus.* (*Pollo Sultano*, Savi). Bill fine red; legs and feet fleshy red; irides lake-red; cheeks, throat, sides of the neck, and chest turquoise-blue; remainder of the plumage deep dull indigo blue, having the edges of the greater and lesser coverts of the wings lighter in colour and more brilliant; under tail-coverts white (Gould.)

"Independently of the southern and eastern parts of Europe, the marshes of which are the places of constant resort for this beautiful bird, its range is extended," says Mr. Gould, "over a great portion of Africa to the south, and as far as the mountains of the Himalaya to the east. In Europe it is especially abundant in the Grecian Archipelago, the Levant, and the Ionian Islands; it is less common in Dalmatia and Sardinia. The southern provinces of Hungary and Russia and the borders of the Caspian Sea may also be enumerated among its European localities." M. Temminck states that it is to be seen in many cities of Sicily (where, according to M. Cantraine, it is very common in the neighbourhood of Lentini), that it is not known in Dalmasia nor Calabria, and is rare in Sardinia; and that it is known in Catania under the name of Gallo-Fagiano.

(6752) *Fulica.*—Bill as in the *Porphyrio*, but more slender; the base straight; the gonys short and angulated. Feet very large; the toes margined with a lateral membrane, which is either narrow and of equal breadth or dilated into lobes. The natatorial type. (Sw.)

(6753) *F. atra.* It is the Foulque, Macroule, or Morrelle, of the French; Schwarzes Wasserhuhn of the Germans; Meir Koet of the Netherlanders; Folaga and Folacra of the Italians; Blas-Klacka of the Swedes; Vand-Hoene and Bles-Hoene of the Danes; Jar Ddwfr Foel of the Welsh; and Coot of the English. Some have though that it is the Κέπφος, of Aristotle. It is found throughout Europe, in marshes, lakes, and gulfs; very abundant in Holland and in the lakes of the interior of France, less numerous in Germany and Switzerland. Dr. Von Siebold and M. Burger saw it in Japan.

(6754) *Gallinula.*—Bill short, straight, the margins not inflexed; the cutting edges of the upper mandible folding over the lower. Gonys very short, angulated. Toes simple, without any marginal membrane. The rasorial type. (Sw.)

(6755) *G. chloropus* is the Poule d'Eau of the French; Gallinella of the Italians; Wasserhuhn Grunfassige Rohrhuhn, and Braune Meerhun, of the Germans; Common Gallinule, Water-Hen, or Moor-Hen of the English; and Dwfriar of the Welsh. This species appears to be not only dispersed over the whole of Europe, but extends its range over the greater portion of Africa and India; and, like the Peregrine Falcon and Barn-Owl, may be said to be universally distributed over the globe. "It is even questioned," says Mr. Gould, "whether those from tropical America, China, and the islands of the Pacific, which exhibit the most trifling marks of difference, should not be considered as identically one and the same species." It was seen by Dr. Von Siebold and M. Burger in Japan; and M. Temminck remarks that the African variety, which is also found in the isles of Sunda, has the anterior border of the wing reddish; the

lower tail-coverts, which in European, Asiatic, and Japanese individuals are of pure white or Isabella colour, have a reddish tinge in the variety from Africa and the Sunda Isles which is also somewhat less than European and Japanese birds, and has the frontal plate larger. The variety from the Sunda Isles is, according to M. Temminck, *Gallinula orientalis* of Horsefield, ('Linn. Trans.,' vol. xiii.) The only difference between the Japanese bird and that of Europe is the Isabella tint of the lateral under tail-coverts in the former: in the European variety those feathers are white.—*Eng. Cyc.*

(6756) RAMALINA FURFURACEA. LICHENS. Angola weed.—*Simmonds' Comml. Product. p.* 486.

(6757) RAMBEH, the Malay name of a fruit described by Mr. Jack as being common in the peninsula of Malacca, but unknown at Bencoolen, while the Choopa, which is nearly allied to it, is abundant at the latter, but is not found at the former place. The fruit is that of a tree called *Pierardia dulcis*, of the natural order of *Sapindaceæ*. Another species of the same genus is called *P. sapida*, from its also yielding an edible fruit. It is found in the district of Tippera, to the eastward of Calcutta, and also in China, where it is cultivated for its agreeable fruit, according to information obtained by Dr. Roxburgh from Chinese gardeners. It is remarkable that it should there be called Lutqua, as it is called Lutco by the Hindoos on the eastern frontier of Bengal.—*Eng. Cyc.*

(6758) RAMBOOTAN, a Malay fruit, [SAPINDACEÆ.]

(6759) RAMI TSJINA, *i. e.* "CHINESE RAMI," a name given by the Malays to the jute; the true hemp; and the urtica nivea.—*Royle.*

(6760) RAMONDIA PYRENAICA. GESNERACEÆ. This is an Alpine plant, growing in a common soil, not likely to thrive here.—*Riddell.*

(6761) RAMPHASTIDÆ, a family of Scansorial Birds known by the common name of Toucans.—*Eng. Cyc.*

(6762) RAMTILLA, a genus of Plants belonging to the natural order *Compositæ* and the sub-tribe *Helianthea*, so called from the Indian name Ram-Till, by which the oil of its seed is designated. The plant is remarkable for the number of names by which it has been described by botanists. Of these we need only mention the *Verbesina sativa* of Roxburgh, and the *Ramtilla oleifera* of De Candolle. Cassini had however previously formed it into a new genus, and, under the name of *Guizotia*, "dedicated it to the celebrated historian, then minister of public instruction." This name, being prior to that of *Ramtilla* by a year or two, is now retained as that of the genus. De Candolle, having obtained specimens and seeds from various countries, discovered that the Indian plant was identical with one from Abyssinia, which has been mentioned by Bruce under the name of *Polymnia frondosa*. The fact is interesting in a plant cultivated in both countries for the same purposes, and forming one of the links which indicate the connection which existed in early times between India and Upper Egypt. This plant is cultivated in different parts of India, from October to March, in fields, for the sake of the seed, from which an oil is expressed, and used as a substitute for that of the *Sesamum*, which is considered the best kind. It is used both in dressing food and as a lamp oil.—*Eng. Cyc.*

(6763) RANDIA (named after Isaac Rand, M D, once a demonstrator of botany at the Chelsea Botanic Gardens), a genus of plants belonging to the natural order *Rubiaceæ*.—*Eng. Cyc.* Randia dumetorum, 580; floribunda, 583; longispina, 582; nutans, 587; uliginosa, 397.

(6764) RANDIA DUMETORUM. GARDENIA DUMETORUM. *Retz.* Posoqueria dumetorum.—*Roxb. Fl. Ind. i. p.* 711.

Jooz ul-kuch, ARAB. | Mueiphul, HIND.

R. dumetorum, the Bush-Randia, is a thorny branching small shrub or tree, with oval leaves, rather blunt, cuneate at the base, and smooth. The flowers are very sweet-scented, sessile, solitary, mostly terminal; the calyx has oblong lobes, rather shorter than the villous corolla. The fruit is smooth, yellow, resembling a small crab-apple, firm and fleshy. The seeds are oval, numerous and lying in mucus. The fruit when bruised and thrown into water intoxicates and even kills fish, which are still however deemed fit for food. Powdered it is deemed a powerful emetic, but this seems an undeserved attribute. The bark of the root is given in infusion as a nauseating remedy. During search for an efficient substitute for ipecachuana, the fruit of this article underwent examination; for specimens the Bengal Committee were indebted to Drs. Wight and Wallich, and they found these identical with the *muen phul* of the Bazars. The results of our experiments shew that little or no dependence can be placed on the fruit as an emetic remedy.—*O'Shaughnessy.*

(6765) RANDIA ULIGINOSA, the Bog Randia, has almost terminal opposite thorns, tetragonal branches, oblong leaves somewhat cuneated, glabrous. The flowers solitary, sessile, almost terminal. It is a native of the East Indies, in moist places. The flowers are large, white, and fragrant, and in twos or threes at the top of the branchlets. The berry is about the size of a pullet's egg, ash-coloured or olive-gray, and 2-celled. The seeds are flattish, nestling in the pulp. The flowers of this species render it deserving of a conspicuous place in the hot-house.

(6766) RANINIDÆ, a tribe of the family *Apterura*, belonging to the section of Anomoureus Decapod Crustaceans. This tribe, in its general form and in the conformation of its feet, approaches very closely to the *Hippidæ*, and especially to the *Albuneæ*. [HIPPA.]

Raninа dentata may be taken as an example of the tribe. It inhabits the Indian Seas; Mauritius.

(6767). RANUNCULACEÆ, CROWFOOTS, a natural order of Exogenus Plants. There are about a thousand known species, of which 1-5th is found in Europe and 1-7th in North America. Ranunculaceæ, are chiefly natives of temperate climates, a few only being found in India within 25° north latitude; of these, all but eight or nine are, according to Dr. Wight, natives of the hilly districts. Nearly 100 species have been discovered in the Himalayas. The majority of the Ranunculaceæ contain an acrid principle, volatile at the temperature of boiling water, and capable of producing inflammation and vesication, if brought in contact with the skin. The taste is stimulating and acrid; if swallowed either in substance or solution, many of these plants occasion violent purging and vomiting, sinking of the pulse, cramps, collapse, and death. Some contain a powerful narcotic alkali named *Conitiana*, of much value in the treatment of rheumatism, and neuralgic diseases. Others are bitter tonics, devoid of poisonous properties, or slightly aperient. Lastly, the seeds of one species (Nigella) contain a somewhat aromatic essential oil, are valued as a spice, and much used as a popular stimulation.—*O'Shaughnessy, page* 159. The illustrative genera are—*Aconitum*, which furnishes Aconite, or Monk's Hood. [ACONITUM] *Clematis*. [CLEMATIS.] *Coptis* [COPTIS] *Delphinium*, the species of which are known as Larksspurs. [DELPHINIUM.] *Helleborus*, the Hellebore of the ancients, famed as a drastic purge. [HELLEBORUS; PÆONIA] *Nigella*. [NIGELLA.] *Ranunculus*, Crowfoot, or Buttercup, whence the order is named. [RANUNCULUS, (Lindley, *Vegetable Kingdom*; Balfour, *Class-book of Botany*.)—*Eng. Cyc.*

This term, *Ranunculus*, is derived from 'rana,' frog, because many of the species inhabit humid places frequented by that reptile. The genus is the type of the natural order *Ranunculaceæ*. It has 5 sepals, occasionally 10, with a nectariferous excavated scale at the base. The stamens and ovaries are numerous, the achenia ovate, somewhat compressed, mucronate, arranged on globose or cylindrical receptacles. The species are mostly acrid, and if applied when fresh to the skin will produce blisters; this quality is destroyed by drying or by heat.—*Eng. Cyc.* Wight gives Ranunculus reniformis, 75; subpinnatus, 49; and Wallichianus, 937.

(6768) RAPE.—BRASSICA NAPUS. This plant yields the Rape seed of commerce. Used as salad similar to mustard, the leaves are however eaten when the plant is in seed, of no great value as a vegetable, cultivated like Mustard.—*Jaffrey*. This plant is of the Cabbage Tribe, is cultivated like cole, or colza, for the sake of its seeds, from which oil is extracted by grinding and pressure. It is also extensively cultivated in England for the succulent food which its thick and fleshy stem and leaves supply to sheep when other fodder is scarce.—*Eng. Cyc.* For the products of this plant, we refer to the following articles:—

(6769) RAPE-OIL.

Sursee or surrus Teil. GUZ. HIND.

The oil expressed from rape seed, which is extensively consumed in France, and other parts of the Continent for illuminations, &c. This oil is exported from Bombay to England and France.—*Faulkner*. The seeds of *Brassica rapa* and *B. napus* are valuable for the large quantity of oil which they yield by expression. [See OILS and FATS.] *B. rapa* yields the largest quantity of oil. *B. campestris* yields a superior oil known in France as *Colza* oil. Rape oil is thick, of a yellow colour, and with a peculiar taste and smell; it concretes into a yellow mass at about 28°. Its specific gravity is 0·9167. It is used in the preparation of woollen goods and of some kinds of leather. It is much used in France for burning in lamps. Colza-oil may be used without purification, and it is largely employed in lighthouse lamps in Europe. The common kind of oil is purified by being agitated with a 200th part of sulphuric acid, left to repose for 24 hours, when two-thirds of its bulk of water at 165° are added, and the mixture stirred until it becomes milky. It is then kept for 2 or 3 weeks in a room heated to 80°, when it becomes clear by the deposition of a dark coloured sediment. It is lastly filtered by being drawn off into vats the bottoms of which are pierced with holes stuffed with filaments of carded wool or cotton. Having passed through this filter the oil is fit for use. The acid may be removed by the addition of powdered chalk.—*Tomlinson*.

(6770) RAPE SEED.

Roefero, DAN.	Sursee, Surrus, GUZ. HIND.
Graine denavette, FR.	Shershapa, SANS.
Rapsaat, GER.	

The produce of a hardy biennial plant, of the cabbage tribe (*Brassica rapa*), extensively cultivated in England and on the Continent, on account of its seeds, which are crushed for oil, and partly for its leaves, which are used as food for sheep. In India, it is also extensively cultivated, whence both the seeds and oil are largely exported to England and France.—*Faulkner*.

(6771) RAPE SEED CAKE. Is the adhering masses of the husks of rape seed, after the

oil has been expressed. It is employed, like linseed cake, to feed cattle and pigs on the Continent; and as manure in England.—*Faulkner.*

(6772) RAPHANUS, a genus of Plants belonging to the natural order *Cruciferæ*. It is mostly remarkable for containing the common radish, *Raphanus sativus*. This plant, a native of China, has been cultivated in Great Britain for upwards of 250 years, and has given rise to numerous varieties, which are divided into long-rooted or spindle-shaped, and round or turnip-rooted. They are also denominated spring, summer, autumn, or winter radishes, according to the season in which the respective sorts are found best adapted for use.—*Eng. Cyc.*

(6773) RAPHIS. Most of the coir used by the Chinese is made from the bark of the coir palm, (*Raphis flabelliformis*) called, *tsung*, which is stripped off in large sheets from the trunk of the tree; when steeped in water the fibres separate in short wiry threads, of a dark brown color, having all the properties of the cocoanut coir. It is the material from which the cordage in Chinese vessels, and sometimes the cables, is manufactured; brooms, rain cloaks, sandals, hats, brushes for block printing, twine, and other articles are also made from it. The Raphis grows all over southern China, attaining at times the height of 30 feet and upwards; the bark is stripped off every year. The price for the prepared coir is about $ 4 per pecul. Another kind of coir is also in extensive use in the Archipelago for rigging; it is called *gomuti* or *ejoo*, and the thread sells at $ 1.50 or $ 2 per pecul. The best comes from Amboyna.—*Morrison.*

The Ground ratans, the excellent walking-sticks known to the English under this name, are made from the Raphis flabelliformis, which grows in Liu-kiu in Southern China.—*Seeman.*

(6774) RAPHUS, Brisson's name for the Dodo. [DODO.]

(6775) RAPTATORES, the name assigned by Mr. Vigors to the Birds of Prey.

The *Raptores* of Mr. Vigors form his first order, and the following families are arranged by him under it.—VULTURIDÆ, FALCONIDÆ, STRIGIDÆ, *Gypogeranidæ* (?).

The *Raptores* of Mr. Swainson comprise the families of *Vulturidæ*, *Falconidæ* and *Strigidæ*.

Mr. G. R. Gray also makes the *Raptores* consist of the families *Vulturidæ*, *Falconidæ* and *Strigidæ*.

(6776) RAPTORES, Illiger's name for his third order of Birds, comprehending the Birds of Prey.

(6777) RASPBERRY.—Vide, RUBUS.

(6778) RATINARIA, a solitary specimen of Lichen, with a fragment of the black extractive matter, (in a mass) was forwarded from Nelson. Illustrations of the practical use of this new dye, and a chemical analysis of its constitution are required to enable the Jury to give an opinion of its value.—*M. E. J. R.*

(6779) RATAN (Calamus).

Rotan, MALAY.	Bed HIND.
Panjalin. JAVAN.	Betum, TEL.
Kowe, SUNDA.	Piramboo, TAM.

In Malay, rotan, an abbreviation of raotan from the verb raot, to pare or trim, that is, the object pared or trimmed. Of this universal product of the forest of the islands, the name, as might be expected, is different in all the different languages. Thus, in Javanese, it is pánjaliin and in Sunda Kowe. The plants which yield ratans are considered by botanists as a genus of the family of palms, which consists of many species, from the girth of a goose-quill to that of a stout walking stick. They are abundant in all the forests of the Malay and Philippine Archipelagos, and are every where extensively used as cordage or ligatures, or in the manufacture of mats and basket-work. These singular plants creep along the ground or climb trees, and, according to the species, to the length of from 100 to 1,200 feet. The principal places of production for the general market are Sumatra, Borneo, and the Peninsula. By far the most valuable, probably a distinct species, is brought from Banjarmassin on the southern coast of Borneo, for in the market they are worth about 150 per cent. more than any others. A vast quantity of ratans are exported from the Malay Archipelago to Europe, Hindustan, and China.—*Crawfurd Dict: page* 365. The Rattans of Commerce, though apparently insignificant, form a considerable article of trade; so many as four or five millions of them being in some years shipped from the territories under the Government of the East India Company. They are products of several genera of palms, which all contribute their quota to the general quantity required in the markets of the East and in Europe. Amongst the plants producing them may be named the genus, Calamosagus, of Griffith, with its four species; *C. lariniæfolius*, (*Wallichiæfolius*) termed "*Rotang Simote*"; C. ochriger, "Rotang Donam," with C. scapiger, and C. lacineosus. The Calamosagi are all climbing plants.—*Seeman.* Ratan or cane, is used extensively in Burmah and the Tenasserim Provinces, instead of Cordage. The stays of the masts in the native boats, are usually made of ratans, and they are split up into strings for innumerable purposes, to which cord and twine are usually applied. There are numerous species indigenous in the forests, and the Karens have different names for seventeen species or varieties. Rattans are manufactured by the Chinese into chairs, baskets, and other articles, but their bulk interferes with their exportation.—*Williams'*

Middle Kingdom, Vol. II. *page* 402. The best are the produce of Malacca and the Eastern isles. A coarse description is found in many parts of the Peninsula of India, and there, are used for ordinary purposes, as baskets &c., they also furnish material for the cables of Shakespearian bridges. A coarser description called country rattans, pedda piramboo, *Tam.* moty beyt, *Hind.* Pedda bettam, *Tel.* grows to a great length in most districts of the Peninsula. When green, it is formed into cables for drawing the cars, and in some parts for suspension bridges. It answers better than bamboo for baskets and for strong fences, when interwoven between stakes. The rattan when burnt, yields an ordinary black for paint.—*Rohde. M S.S.* See CALAMUS.

(6780) RAVENSARA. The article imported into China, from India under this denomination is a nut of a dark brown colour, the size of a nutmeg, in smell and taste resembling both cloves and Pimento: internally it is divided into cells, and contains a kernel extremely hot and biting to the taste, with a strong spicy smell.—Ravensara is, also, however, the name given to the bark of the Clove-Cinnamon tree, growing in the Brazils and Madagascar, of which the foregoing is probably the fruit.—*Comp. Descr.*

(6781) REAM. A ream of writing paper consists of 20 quires, of 24 sheets each; and a printer's ream of 21½ quires, or 516 sheets.

(6782) REAUMERIA HYPERICOIDES, has lanceolate flat rather remote leaves. It is a native of Syria and Persia. These plants are elegant little shrubs of easy culture, which thrive well in a mixture of sandy loam and peat; and young cuttings will grow freely in sand under a hand-glass.—*Eng. Cyc.*

(6783) REAUMERIA VERMICULATA, has subulate semi-terete imbricated leaves, crowded on the branches. It is a native of Sicily, Bombay, and Egypt. This plant resembles *Salsola fruticosa*. It is used at Alexandria as a remedy for the itch, being bruised and applied externally, and a decoction taken internally.

(6784) REAUMURIACEÆ. *Reaumuriads*, a natural order of Plants belonging to the Exogenous class. This little order consists of three genera, *Reaumuria*, *Hololachna*, and *Eichwaldia*, which were formerly referred to *Tamaricaceæ*; they have however but little affinity with that order. Their true affinities seem to be with *Hypericaceæ*, near to which Lindley has placed them. The species are generally natives of the coast of the Mediterranean, and of salt plains in the milder parts of Northern Asia.—*Eng. Cyc.*

(6785) RED LEAD (oxide of), MINIUM, CHROMATE OF LEAD

Isroob, ARAB.	Minio, IT.
Minium, FR.	Sindura, SANS.
Mining, GER.	Vermillion, SP.
Sindoor, GUZ. HIND.	Sigappoo Sindoorum, TAM
Temacared, MAL.	Sindoorum, TEL.

Is massicot finely ground and calcined. It is a red powder, but with a liability to become black, and is used in painting, in the manufacture of glass, in surgery, &c.—*Waterston.*

(6786) RED SAND. A specimen of the Cape Comorin red sand (a kind of small garnet) may be interesting, and probably useful, (if brought to notice) for polishing gold and silver, as it appears to be much used by the Natives of this country for that purpose. The other specimens of sand from the same locality, are objects of curiosity, the white being rather peculiar, resembling grains of rice. The whole beach to the westward of Cape Comorin, to the extent of several miles, is generally covered at different seasons with red sand; and immediately on the opposite side, to the eastward, almost entirely with black, which is rather remarkable.—*M. C. C.*

(6787) REED, (of which pens are made.)

Peroo nanal, TAM.	Pedda relloo, TEL.
Baroo, HIND.	

Reeds of the best quality are imported, but inferior descriptions abound on many hills and on the banks of rivers. Reeds for weaving are formed of these, though used also for pens. In Peninsular India, reeds for weavers are constructed by a class of persons, who also practice as oculists, the materials used for reeds are strips of several descriptions of reed: for silk weavers they are made of the fine teeth of the mango fish. —*Rohde M.S.S.*

(6788) REIDLEIA TILIÆFOLIA. BYTTNERIACEÆ. MATHOOREE, *Hind.* A small tree; the young leaves very soft and velvety; flowers small, rose coloured, in axillary and terminal corymbiform panicles, appear in November.—*Riddell.*

(6789) RENNET.

Wfeheh. ARAB.	Paneer Maya, GUZ. HIND. PERS.

The dried contents of the stomach of a calf, used for coagulating or curdling milk.—*Faulkner.*

(6790) REPTILIA, a class of Animals belonging to the sub-kingdom *Vertebrata*, and embracing the creatures usually known as Crocodiles, Lizards, Turtles, Tortoises, Frogs, Toads, and Serpents. These include the AMPHIBIA, CROCODILIDÆ, CHELONIA, OPHIDIA, and SAURIA, and we here propose to give a slight sketch of their history, and the attempts made at their general classificaton. The ancient monuments of the Egyptians prove that the great groups of the tortoises, the lizards, the serpents, and the frogs, as well as their habits, were well known to that people; and the sacred Scriptures abound in passages (the Old Testament especially) showing that a similar knowledge obtained when they were written. Indeed from the earliest times these forms must have attracted the attention of man; and a natural desire on his part to ascertain which of them were dangerous,

and which were innocuous, must have led him to particular inquiry in order to solve the doubt. In Herodotus and Athenæus there are not wanting passages indicative of precise notions respecting many species of reptiles.

The *Amphibia* form, in the last edition of the 'Systema Naturæ,' published by Linnæus himself, the third class of the animal kingdom. This class consists of three orders:—

1. *Reptiles*, which are described as 'pedati, spirantes ore.'

2. *Serpentes*, which are characterised as 'apodes, spirantes ore.'

3. *Nantes*, which are characterised as 'pinnati: spirantes etiam branchiis lateralibus'

The last order, which consists of cartilaginous and other fishes, forms no part of our present inquiry, which is confined to animals included in the two first.

The Count Lacépède (1788-90) divided the Reptiles into three great groups:—

1. Oviparous Quadrupeds, subdivided into (1) those which possess a tail, and (2) those which are tailless.

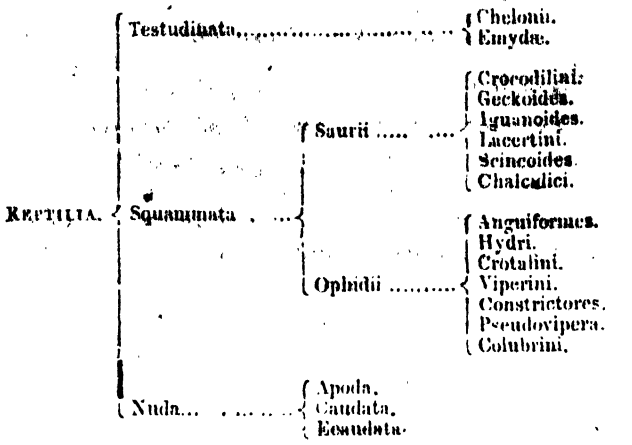
2. Biped Reptiles.

3. Serpents.

In 1799 the method of M. Alexandre Brongniart was read to the French Academy of Sciences, and it seems to have been first published in the 'Bulletin des Sciences,' in 1800; it was afterwards printed among the other Memoirs of the National Institute. His classification may be regarded as a considerable step in advance of those who had preceded him, and had principally confined themselves to external characters, well defined doubtless, but of little moment when compared with those based on organisation and habits. Whilst they carefully attend to the presence or absence of tail or feet, they neglected those essential points which spring from generation and development. Brongniart pointed out the approximation of the Tortoises to the Lizards, and even to the Serpents, and was the first to show that the Toads, Frogs, and Salamanders, ought to constitute a separate order.

M. Brongniart recognised the following orders:—

1. Chelonians (Tortoises).
2. Saurians (Lizards).
3. Ophidians (Serpents.)
4. Batrachians.



The method of Lacépède seems to have found more favour in the eyes of M. Latreille than that of M. Alex. Brongniart, which last must have been known to the former when he published his 'Natural History of Reptiles,' in 1801. He placed in his first division the Oviparous Quadrupeds, whose body is provided with feet, dividing them into two sections, according as they have unguiculated, or clawless toes, and a scaleless skin. His second division is formed by the Serpents; and in his third, designated by the name of Pneumobranchians, he places the genera *Proteus* and *Siren*, as well as another, which he names *Ichthyosaurus* which last is only a Tadpole.

In 1825, when the science had very much advanced, M. Latreille, in his 'Families of the Animal Kingdom,' published another arrangement, which Messrs. Dumeril and Bibron have digested into the following table:—

HEMACRYMES PULMONEES.

Classes.	Sections	Orders.	Families.
Reptiles.	Cuirassed.	Chelonians	Cryptopods (*Testudo*, &c.).
			Gymnopods (*Sourochelys, Trionyx*, &c.).
		Emydosaurians	Crocodilians (Crocodiles. &c.).
	Scaly. Saurians.	Lacertiform.	Lacertians (*Monitor* &c.).
			Iguanians (*Iguana*, &c.)
			Geckotians (*Gecko*, &c.).
			Chameleonians (*Chamæleo*, &c.).
		Anguiform.	Tetrapods (*Scincus, Seps Chalcides*).
			Dipods (*Bipes, Bimanus*)
			Apods (*Anguis, Ophisaurus*, &c.).
	Scaly. Ophidians.	Idiophids	Amphisbænians (*Amphisbæna*, &c.).
			Cylindrical (*Tortrix*)
			Coluberians (*Acrochordus, Boa, Python* &c.)
			Anguisipers (*Bongarus, Hydrophis, Pelamys* &c.).
			Vipers (*Crotalus, Berus, Naja*, &c.).
		Batrachophids..	Gymnophids (*Cæcilia*).
	Amphibia.	Caducibranchians	Anurous (*Pipa, Bufo, Rana*, &c.).
			Urodeles (*Salamandra, Triton, Axolotl*).
		Perennibranchians	Ichthyoids (*Proteus, Siren*).

In the short notice published by George Cuvier, in his 'Tableau Elémentaire de l'Histoire Naturelle' (1798), he divided the Reptiles, like Lacépède, into Oviparous Quadrupeds, Serpents, and Biped Reptiles. Oppel (who had been a diligent attendant M. Duméril's course of lectures in 1807 and 1808, and in whose works much of the lessons of the latter are to be traced, as Oppel himself acknowledges, after publishing the 19th volume of the 'Annales du Muséum,' a Memoir on the Ophidians, and another on the Batrachians, produced, in 1811 at Munich, his treatise 'Die Ordnungen, Familien, und Gattungen der Reptilien, als Prodrom einer Naturgeschichte derselben' (thin 4to.). The following synoptical table exhibits Oppel's method:—

In 1790 Merrem published a paper in German, with the title of 'Materials for a Natural History of Amphibia,' and in 1820 and 1821 two other papers followed. These papers treat of serpents and several genera of Saurians, and are illustrated with coloured plates. But his system appears to have been published (in 1800) at the suggestion of Bechstein, who had translated Lacepede's 'History of Reptiles' into German; and in 1820 a second edition of this system, which is shown in the following table, made its appearance:—

Classis	Ordines.	Tribus.	Subdivisions.
Phelidota.	*Testudinata*	with feet	Pinniform. Digitated.
	Loricata (Crocodiles).		
		Gradientia	*Ascalabotæ. Sauræ. Chalcidici.*
		Repentia (Anguis Ophisaurus, Acontias).	
	Squammata	*Serpentia*	Gulones. *Innocui. Venenati*
			Typhlini.
Batrachia.		*Incedentia* (Chirotes.) *Prendentia* (Chamæleon).	
		Apoda (Cæcilia). Salientia (Rana, &c.).	
		Gradientia with eyelids.	*Mutabilia (Salamandra, &c.).*
		Gradientia without eyelids.	*Amphipnœsta* (Hypochthon, or Proteus).

M. De Blainville, in 1816, published in the 'Nouveau Bulletin des Sciences de la Societe Philomatique,' the prodromus of his systematic distribution of the animal kingdom, which he produced, in 1822, in his 'Principes d' Anatomie Comparee.' Under the type *Osteozoaria*, and the sub-type *Ovipara* or *Anastozaria*, he places the Reptiles, which he divides into two classes, namely—1, Reptiles or Ornithoid Squammifers; 2, Amphibians or Nudipellifers, Naked Ichthyodians.

The First Class is separated into three orders,—

I. Chelonians, consisting of the genera *Testudo. Emys. Chelys. Trionyx, Chelonia*, and *Dermocheys* (Sphargis).

II. Emydosaurians, or Crocodiles, divided into three sub genera.

III. Saurophians, or Bihentians, which are separated into two sub orders:—

A. Surians, consisting of the families of Geckoidians, Agamoidians (the Norma, as *Agama* and *Basiliscus*, and the Anormal, as *Chamæleo* and *Draco*), the Iguanoidians, *Tupinambis*, and the Lacertoidians (divided into Tetrapods, Dipods, and Apods).

B. Ophidians, which are divided into—

1. The Dipods (Chirotes).
2. Apods:—*a* (with numerous teeth). *Pelamys, Hydrophis*, the Vipers, and the Lethifers: B (without venomous teeth), the Amphisbænas, the Climbers or Boas, and the Colubers.

The Second Class, Ichthyoid or Nudipelliferous Amphibians, is composed of four orders:—

1. The Batrachians, divided into two sub-orders—*a* (Aquiparous), *Rana*, &c.; B (Dorsigerous), *Pipa*.
2. The Pseudosaurians or Salamanders.
3. The Subichthyans, or True Amphibians (*Proteus, Siren*).
4. The Pseudophidians (*Cæcilia*).

Dr. John Edward Gray published in 1825 his 'Synopsis of the Genera of Reptiles and Amphibia, in the 'Annals of Philosophy.' He considers the Reptiles, or scaly-skinned group, and the *Amphibia*, or naked-skinned group, as distinct classes.

The class *Reptilia* are thus divided:—

§ 1. Body covered with imbedded hard plates; legs distinct, fit for walking. *Loricata*, Gray, not Merrem.

Order I. *Emydosauri*, De Blainville.

Families.—1, *Crocodolidæ*; 2, *Ichthyosauridæ*; 3, *Plesiosauridæ*.

Dr. Gray thinks that *Megalosaurus* of Buckland is perhaps allied to in this order.

Order II. *Sauri*, De Blainville.

Section 1. Tongue not extensile. *Ascalabota*, Merrem.

Families: 1, *Stellionidæ*; 2, *Geckotidæ*.

Section 2. Tongue extensile. *Saurœ*, Merrem.

Families: 3, *Tupinambidæ*; 4, *Lacertinidæ*; 5, *Chamæleonidæ*.

Order III. *Saurophidii*, Gray.

Section 1. Body covered with imbricate scales anus transverse, not terminal; tongue extensile.

Families: 1, *Scincidæ*, Gray; 2, *Anguidæ*.

Section 2. Body covered with intricate (imbricate?) scales; anus terminal.

Family: 3, *Typhlopidæ*, Gray.

Section 3. Body covered with rings of square scales.

Families: 4, *Amphisbænidæ*, Gray; 5, *Chalcididæ*.

Order IV. *Ophidii*, Brongn. (*Serpentes*, Linn.)

Section 1. Upper jaws with fangs only. *Venati*. (*Venenati* must be meant.)

Hypnale—Morrem. Scutæ 142, Scutellæ 39–17. rows of scales. Not uncommon in forests in Malabar. Dr. Jerdon has not seen it longer than 16 or 17 inches.

(6799) *Trigonocephalus Elliotti*, n. s. Form massive; 23 rows of scales on the body; Scutæ 151, Scutellæ 43. Olive-green above; pearl-white beneath; poison-fangs small; head covered with plates. Up to 2 feet and upwards long. Dr. Jerdon, only procured this on the Neelgherries, towards the lower portion of the plateau. Dr. Cantor tells him that "the shields of the crown of the head resemble those of Trig. blanchoffi, Schlegel.

(6800) *Trigonocephalus* (*cophias*) *viridis*. Merrem. Russ. 1, pl. 9. 21 rows of scales, 154 Scutæ, 60 Scutellæ. Rare, Dr. Jerdon only got it from the Eastern Ghats.

(6801) *Trigonocephalus* (*cophias*) *malabaricus*. n. s? Very closely allied to T. nigromarginatus. Has 21 rows of smooth scales. Scutæ 145 to 149. Scutellæ 48 to 53. Green above, with brown transverse and zigzag markings. Up to 2 feet long nearly. Not uncommon in all the forests of the West Coast.

(6802) *Trigonocephalus* (*Cophias*) *Neelgherriensis*. n. s ? Of small size, dark brown with black markings. 23 rows of carinated scales. Scutæ 142. Scutellæ 36. Not uncommon in woods on the Neilgherries.

(6803) *Trigonocephalus* (*Cophias*) *Wardii* — n. s.? Has 21 rows of carinated scales. Scutæ 154. Scutellæ 51. Greenish colour, with purplish-brown diamond spots on back and sides; 12 to 14 inches long. The scales of the head resemble those of T. sumatranus, Raffles, according to Cantor (*in literis.*)

(6804) *Vipera Russellii*—Gray. Russell 1, pl. 7. '*Kunnadi Vyrien*' of Tamools. This well known and justly dreaded snake grows to a large size. Dr. Jerdon is strongly inclined to believe that the far-famed *Cobra monil*, or *Cobra manilla* of some, is merely the young of this species. The old orthography is *manil*, which simply means a chain or necklace, and whoever looks at the markings of this snake, especially of the young one, must be struck with the resemblance thereof to a necklace: both *Cobra capella* and *Cobra monil* are Portuguese names, and little doubt, the latter name was given to our present species by the Portuguese. It has however been forgotten as applied to this viper, and may now be considered a fable; for every one you meet is able, on his own showing, to point you out the *real Cobra monil* as quite distinct, and what is more remarkable, no two observers describe it alike, they only agree in its being a very small and a very deadly snake. He here adds that the *carpet snake*, another household word in the Madras army, appears to him to be equally fabulous, as he has not been able to identify it among the venomous snakes, several prettily marked innocent species having been, at different times pointed out to him as the carpet snake. [Generally, Mr. Bligh thinks the little harmless Lycodon aulicus (as indeed mentioned afterwards by Mr. Jerdon), is known as the Carpet snake and this, perhaps, from its habit of entering houses as much as from its markings.—*Cur. As. Soc.*]

(6805) *Vipera echis*—Schlegel. V. noratta—Shaw. Russell 1, pl. 2. *Kutta vyrien* of the Tamools. This little snake is very common in the Carnatic. Dr. Jerdon does not think its bite would prove fatal to man. He has known a dog bitten by one to recover.

The above are all the venomous land snakes Dr. Jerdon had yet met with in Southern India. Of these the only ones at all common are the Cobra, the Chain Viper (Vipera Russellii), the *Bungarus candidus*, and the little *Vipera echis*. Most of the others are peculiar to the forests of India. The Trigonocephali are not usually fatal. He has known several cases of bites by *Trigonocephalus malabaricus*, and *Trig. nepa*; and none proved fatal. Great pain is experienced, and swelling usually follows, but the patient gradually recovers. He himself was bitten in the fore-finger by the *Trigonocephalus neelgherriensis*; He applied a ligature round the finger, and sucked the wound vigorously. In a minute or so the skin round the bite blackened, and in a minute or two more a perfectly circular bit of the skin came off in his mouth. He set off running immediately he was bitten, and felt no further ill effects. See Cantor's remarks on the bite of *Trig. sumatranus*, Journ. As. Soc., Calcutta, XVI, 1044-6; also Blyth, *ibid.* XX, 524.

PELAGIC.

Fam. HYDRIDÆ,—Bon,

(6806) *Hydrophis colubrina*—Schlegel, var. ? —n. s. He possesses what is apparently a variety of this species of sea-snake. It differs from the finished drawing of the species in Cuvier's Regne Animal (Edit. des Eleves), in the black markings meeting on the back and abdomen, thus forming a series of light-coloured oval spots on the sides; the abdominal scutæ commence nearer the mouth, having only 3 or 4 series of small scales between them and the elongated mentals; the scutæ are above 300 in number, and the rows of scales are from 35 to 45—whilst in H. colubrina the scutæ are only 246—and the rows of scales 25. My only specimen is a young one procured at Madras.

(6807) *Hydrus schistosus*, Daud.—Russel 2, pl. 10. Up to 4 feet long nearly. Very common at Madras.

(6808) *Hydrus pelamidoides*, Schlegel. Not common at Madras.

(6809) *Hydrus bicolor*, Schneider—Russell 1, pl. 41. Rare at Madras.

(6810) *Hydrus Striatus*, Lacep.—Russell 2, pl. 9? Not rare at Madras, up to 6 feet in length.

(6811) *Hydrus nigrocinctus*, Daudin.—Russell 2, pl. 6. Common at Madras.

(6812) *Hydrus Cantori, n. s.—H. Nigrocinctus*, var.—Cantor, J. A. S. C. XVI, 1050. Dr. Cantor described this as a variety of the last, in his valuable Catalogue of Malay Reptiles. Dr. Jerdon forwarded him a specimen in 1848, and he remarked as follows on it. "From the examination of this specimen, the second I have seen, I am induced to believe it a distinct species, and not a variety of nigrocinctus." It differs from this last species in the more robust make, larger scales, there being only 21 rows on the body, and larger abdominal scales, especially near the head; also in the shorter triangular head, &c. &c. Dr Jerdon never saw it at Madras, but it is not rare at Tellicherry on the Malabar Coast. Up to 2 feet in length.

(6813) *Hydrus Gracilis*, Shaw—Russell 2, pls. 7 and 8. The number of rows of scales vary from 26 to 35 on the neck, and from 44 to 51 on the trunk. Scutæ 350 to 450. Scutellæ 50 to 60. Very common at Madras. Very remarkable for the small circumference of head and neck compared to that of the body. Up to 4 feet long. All the above sea-snakes are venomous, and their bite to be dreaded.

Fam. BOIDÆ—Bon.

(6814) ACROCHORDUS GRANULATUS, (Schneider)—A. FASCIATUS, Shaw.

Rare—Found sometimes in back-waters.

(6815) *Python molurus*, (L.)—*P. Tristitatus*, Schl.—Russell 1, pl. 22. *Boa*, or Rock snake, of Europeans in Madras. Found all over the country. Dr Jerdon has not seen a specimen longer than 19 feet long. This was killed in Travancore, after having swallowed a doe spotted deer.

(6816) *Boa* (*Gongylophis*) *conica*, Schl.—Russell 1, pl. 4. Not rare in the Carnatic and Malabar. It is considered venomous by some of the natives. Has a very malignant aspect. Up to 18 inches long and upwards.

(6817) *Xenopeltis? trivirgatus*—n. s. Brown above, with a triple series of black marks—beneath white, black-banded; of a shining nacreous lustre throughout. Scutæ 137. Scutellæ 29. 13 rows scales. Dr Jerdon has only found this on the Neilgherries.

(6818) *Tortrix eryx*, Schlegel—var.? Two-headed snake of many: common. Scutæ 205. Scutellæ 36.

(6819) *Cylindrophis maculatus?* This, Dr. Kelaart has sent to the Society's Museum from Ceylon.—*Cur. As. Soc.*

(6820) *Cylindrophis curticeps*.—n. s. Differs from the last in its shorter, more triangular head, &c. &c.

(6821) *Cylindrophis macroscelis*—n. s.? Differs from both in the much larger scales. These last three small species are not very common. They are sometimes found on the surface of the ground in rainy weather, but are generally dug out of the earth. They are called earth snakes by the natives.

Fam. TYPHLOPHIDÆ

(6822) *Pilidion? montanum*—n. s.? Above bluish-black, yellow on the sides, with a black spot on each of the 3 lower scales; abdomen banded black and white. Scutæ? Scutellæ 15. 15 rows of scales. 15 inches long. Found only on the Neilgherries.

(6823) *Uropeltis ceylonicus*.

(6824) *Uropeltis affinis*—n. s. Differs from the last in its smaller scales, in the abdominal scutæ being larger, and commencing sooner. They are both rare. Dr. Jerdon procured them on the Western Coast.

(6825) *Onychocephalus acutus*—Dum. et Bibr. Dr. Jerdon possesses one example of this curious reptile, which he procured in the Carnatic at Nellore. Dr. Cantor remarks, "Described from an unique specimen, habitat unknown."

(6826) *Typhlops braminus*, (Daud.)—Russell 1, pl. 43. [This group, the Argyrophis of Mr. Gray, requires to be studied, as several species appear at present to be confounded. The Society's Museum has lately received Typhlops Russelli, Gray, from Chyebasa. *Cur. As. Soc.*] Common under stones in the rainy season, usually called earthworm.

(6827) *Calamaria sagittaria*—Cantor. A specimen sent to Dr. Cantor was so named by him; it had only 170 Scuta and 70 Scutella. It is not rare in forests in Malabar.

(6828) *Coronella tæniolata* 1, pl. 19? 15 rows of smooth scales; Scutæ 185. Scutellæ 41. This species is referred to *Tropidonotus stolatus* by Cantor, but a snake that Dr Jerdon possesses and which answers tolerably well to Russell's description and figure, appears to be a true Coronella. It is common at Madras.

(6829) *Xenodon venustum*, n. s.?—[*X. purpurascens*, Schlegel]. Above olive-brown with a triple series of irregular black spots, the central one edged with pale yellow; some transverse marks on head and neck. Has 17 rows of scales. Scuta 142. Scutellæ 31. Rare—found on the West Coast only; 1 foot long.

(6830) *Xenodon dubium*—n. s.? Of a pale earthy brown colour, lighter on the side; a series of darker marks, irregular in shape, and edged with black. Scutæ 181. Scutellæ 41. Has 15 rows of scales. Rare. Dr. Jerdon procured it in N. Canara.

(6831) *Lycodon Russellii*—Russell 1, pl. 35. Scutæ 193. Scutellæ 47. 17 rows of smooth scales. Rather common in Southern India.

(6832) *Lycodon aulicus*, (L.)—Russell 1, pls. 16 and 26. Has 17 rows of scales. Dr. Jerdon's

specimens have only from 165 to 174 scutæ and from 54 to 61 scutellæ, which correspond with Russell's nearly, viz. from 171 to 174 and 40 to 41, whilst Cantor gives from 208 to 257 and from 57 to 91. One specimen which resembles in colour Cantor's var. B, (Lycodon capucinus, Boie,) does not differ in number of the scutæ, &c. Very common all over the country, often called Carpet Snake and considered dangerous, though of course harmless.

(6833) *Lycodon platurinus*, (Shaw). Scutæ 183. Scutellæ 76. Rare in Southern India—17 rows of scales.

(6834) *Lycodon nympha*—Russell 1, pls. 36 and 37, bad figure. 13 rows of scales; Scutæ 234. Scutellæ 87—not rare at Madras.

(6835) *Lycodon assimilis*—n. s. Very similar in colour to the two last species, viz. black with white bands. It differs in having 23 rows of scales. Has 190 scutæ and 60 scutellæ. Dr. Jerdon has mislaid the locality of this species.

(6836) *Coluber Blumenbachii*, Schleg.—Russ. 1, pl. 34. *Dhamin* H.; *Sarray pamboo*, Tam. Perhaps the most common snake in India, grows to a large size, 7 feet and upwards; frequents chiefly marshy-land, paddy-fields, &c. Scutæ 200. Scutellæ 125—17 rows of scales.

(6837) *Coluber fasciolatus*, Shaw.—Russell 1, pl. 21. Scutæ 200. Scutellæ 58. Not uncommon at Madras and elsewhere in the Carnatic. Dr. Jerdon has seen it nearly 3 feet long.

(6838) *Coluber pictus*, Daud. Russell 1, pl. 29. scutæ 202. Scutellæ 91—Russ.

ARBOREAL.

(6839) *Dipsas trigonata*—Russell 1, pl. 15. *Tati katladay*, Tel.; *Peri Suruday*, Tam, Scuta 235. Scutella 83. Common in the Carnatic.

(6840) *Dipsas cynodon*? Dr. Jerdon's specimens correspond very well with the description in Schlegel. Scutæ 240, Scutellæ 110. Rows of scales 21. Up to — feet and upwards in length. Dr. Jerdon only found this snake in forests on the West Coast.

(6841) *Leptophis pictus*, (Gmel.)—Russ. 1, pl. *Kumberi mukar*, T.; *Chectooriki pambu*, Tam. 176 scutæ and 140 scutellæ—15 rows of scales. Very common in all parts of the country.

(6842) *Leptophis? Bellii*?—n. s. Scutæ 173. Scutellæ 64. Green above, with dark line on the sides bordered on each side by a pale stripe—17 rows of scales. This much resembles the drawing of Ahætula Bellii in Grey and Hardwicke. Dr. Jerdon procured one specimen in a grassy plain at Jalnah. It had killed and was swallowing a small *Vipera echis*.

(6843) *Leptophis ornatus*, Shaw.—Russ. 2, pl. 2 Scutæ 209. Scutellæ 129—17 rows of scales. Dr. Jerdon only procured this very handsome snake lately in Malabar.

(6844) *Leptophis*? *nilagiricus*?—n. s. Green above, yellow beneath. Scutæ 140. Scutellæ 73—13 rows of scales. Very common on the grassy hills of the Neilgherries.

(6845 *Leptophis*? *canarensis*? Green above, yellowish beneath with a streak on the sides. Scutæ 140. Scutellæ 57—15 rows of scales. Procured in North Canara. Perhaps these two last belong more properly to *Dryinus*. Of the last Dr. Cantor remarks—"Apparently *Dryinus prasinus*, var. A."—the number of the scutæ, &c. however differs very materially.

(6846) *Dryinus nautus*.—Russell 1, pl. 12. Green whip-snake. Scutæ 180; Scutellæ 158. Common all over the country. Dr. Jerdon lately saw one that had swallowed a Parroquet and became gorged.

(6847) *Herpetodryas malabaricus*,—n. s. Olive brown with a dark streak along the sides, most conspicuous on the posterior portion of body; a series of white spots on the anterior portion of the body, edged with black. Scutæ 222; Scutellæ 91—25 rows of scales. Dr. Jerdon says it is possible that this may be *H. helena*, as he possesses a young one in which the markings differ somewhat, and much resemble those on Russell's figure, which is evidently a very bad one. [Colubber helena is quite distinct.—*Cur. As Soc.*] He procured it in Malabar where it is not very rare.

(6848) *Tropidonotus stolatus*, (L.)—Russell 1, pl. 10 and 11. Scutæ 146; Scutellæ 61—19 rows of scales. Seldom exceeds 18 inches in length; one of the most common snakes in India.

(6849) *Tropidonotus Schistosus*, (Daud.)—Russell 2, pl. 4. Scutæ 140; Scutellæ 85—17 rows of scales.

(6850) *Tropidonotus Plumbicolor*, Cantor. The colour of the living snake is leek-green. Scutæ (in a young one) 143; Scutellæ 36?—21 rows of scales. Found in the Wynaad also in Bundelkund, and about Midnapore.

(6851) *Tropidonotus Monticolus*,—n. s.? Green, with a series of dark spots on the trunk, one on the centre of back and another on each side, the one on the right somewhat in front, the left one posterior, some white marks on the head; Scutæ 132; Scutellæ 85—19 rows of scales; eyes large; 3 feet and upwards in length. Common in the Wynaad, (2 anterior frontals, 3 posterior ditto, lowest scales rhombic).

(6852) *Tropidonotus Piscator*.—Russell, 28 and 33. 19 rows of scales; Scutæ 139; Scutellæ 83. Found in wells and tanks. Very common.

(6853) *Homalopsis rhynchops* (Schneider),—Russell 1, pl. 17. Scutæ 146; Scutellæ 65. Common in estuaries.

(6854) *Homalopsis Enhydris*, (Schneider.—Russell 1, pl. 30. Scutæ 150; Scutellæ 58. Found in the same localities as the last.

BATRAGHIDÆ.

(6855) *Cæcilia Oxyura*,—Dum. and Bibr. Found on the West Coast, but rare.

REPTILIA OF MADRAS.

(6856) *Epicrium Glutinosum*, (L.) Found in Malabar. 2 cirri quite distinct. Probably a distinct species from E. Glutinosum of Ceylon, as sent by Dr. Kelaart. The latter has a strongly marked pale lateral band, and the *cirri* are less developed than they are represented to be in Mr. Jerdon's drawing. Dr. Kelaart, however, obtained a second species, which may be that noticed by Mr. Jerdon; and either may be identical with the *Epicrium* from Assam and from Pinang.—*Cur. As. Soc.*

(6857) *Rana tigrina*. Bull frog. Found all over India.

(6858) *Rana cutipora*,—Dum. and Bibr. In tanks in the Carnatic. Of a beautiful grass green colour, with or without a central yellow stripe on the back.

(6859) *Rana Leschenaultii*,—Dum. and Bibr. The common frog of India.

(6860) *Rana crassa*,—n. s. Of a thick clumsy form, feet webbed to the extremity of the toes; limbs shorter than in R. Leschenaultii, head wider, greenish above with dusky markings. Length $3\frac{8}{10}$ ths; hind leg $5\frac{1}{2}$. Rare—found in a few tanks in the Carnatic.

(6861) *Rana Malabarica*. Found only on the West Coast, and chiefly during the monsoon when it enters houses, and makes a great gobbling, so much like a turkey that some people call it the 'Turkey frog.'

(6862) *Rana Flavescens*,—n. s. Of a buff colour on the back; yellow on the sides; limbs banded; feet webbed nearly to the extremities. Length of one $3\frac{2}{10}$ths; hind leg $5\frac{1}{2}$. Of slender make, pointed muzzle. Found frequenting mountain streams in the forest only.

(6863) *Rana curtipes*,—n. s. Head very wide; muzzle obtuse; limbs rather short; feet webbed to the ends of the toes, except the centre one. Head and back above bright buff; sides deep marroon; legs dark purple with a few white spots; abdomen white mottled. Length of one $2\frac{9}{10}$ths; hind leg $4\frac{1}{10}$th. Found in forest only. Has a very peculiar, rather pleasing call. Chiefly seen during the monson.

(6864) *Rana agricola*,—n. s. Feet not webbed quite to the extremity. Of a greenish colour, mottled with darker. Length of one $2\frac{1}{10}$th; hind leg $3\frac{2}{10}$ths; foot 1. Found in inundated paddy-fields and meadows.

(6865) *Rana Nilagirica*,—n. s. Very much allied to the last, differs in its much longer limbs. Length 2 inches; hind leg $3\frac{7}{10}$ths. Dr. Jerdon has only seen this frog in marshes in the Wynaad and Neilgherries.

(6866) *Polypedates Leucomystax*. 'Chunam frog' of Europeans. Very common all over India.

(6867) *Polypedates Variabilis*,—n. s. Green frog of the Neilgherries. Green, sometimes unspotted, at other times with gold spots or blackish spots; at times golden yellow with brown spots; at other times brown with darker spots. Length $2\frac{1}{2}$ inches; hind leg 4; foot $1\frac{2}{10}$ths. Found in the Neilgherries in the banks of streams and in shrubs.

(6868) *Ixalis? Glandulosa*,—n. s. A small tree frog, with very obtuse muzzle, feet slightly webbed; abdomen largely glandular, tympanum indistinct; green above, yellowish on the sides and limbs. Length $1\frac{2}{10}$ths; hind leg $\frac{7}{10}$ths; foot $9\frac{9}{20}$ths.

(6869) *Rhacophorus Reinwardtii*, Dum. and Bibr. Found in the Malabar Coast on trees, and in grass during the monsoon. Not very common.

(6870) *Limnodytes? Phyllophila*,—n. s. A small frog, with the subdigital disks very slightly dilated; toes not quite completely webbed; tympanum small; reddish yellow, with the sides of the face dark purple. Length $1\frac{1}{2}$; hind leg $1\frac{8}{10}$ths; foot $\frac{11}{20}$ths. Found in all the Western forests among decayed leaves.

(6871) *Phyllomedusa? tinniens*,—n. s. Tinkling frog of the Neilgherries. Fingers opposable; feet webbed at base only; yellowish red, or sometimes blackish above; side of head dark; inner fingers yellow; length $1\frac{1}{10}$th; hind leg $1\frac{3}{10}$ths. Found in grass and among bushes on the Neilgherries. Has a peculiar loud clear metallic tinkling call.

(6872) *Phyllomedusa? Wynaadensis*. Somewhat allied to the last, differs in its larger limbs; larger tympanum, &c. Length about 1 inch. In this when the hind leg is drawn forwards, the end of the tibia reaches the muzzle; in the last it only reaches the tympanum; reddish brown above, limbs barred.

(6873) *Polypedates? saxicola*,—n. s. A small frog with teeth, tympanum distinct, fingers webbed at the base; toes webbed to the extremities; pointed muzzle; dark olive green with dark marbling, and barred limbs. Length $1\frac{1}{10}$th; hind leg $1\frac{3}{4}$th; foot $\frac{5}{10}$th; femur and tibia reach beyond the muzzle. Found on rocks in shady mountain streams in Malabar and Wynaad.

(6874) *Hylaedactylus montanus*,—n. s. Mottled green and brown above, Length $1\frac{7}{10}$th; hind leg 2; foot $\frac{7}{10}$th. Hab. Mountain streams in Wynaad, rare. A very nearly affined species, if not the same, inhabits Mergui.

(6875) *Hylaedactylus carnaticus*,—n. s. Of small size; marbled green and brown; muzzle more acute than in the last species; length $1\frac{3}{10}$th; hind leg $1\frac{3}{10}$th; foot $5\frac{5}{10}$th. Found in the Carnatic during the monsoon, rare.

(6876) *Bufo scaber*, Daudin. Common toad of India. Very abundant.

(6877) *Hyperodon marmoratum*. Found in the Carnatic during the monsoon.

(6878) *Pyxicephalus fodiens*,—n. s. Greenish marbled with brown. Length 2 inches; hind leg $2\frac{8}{10}$ths; foot $\frac{8}{10}$ths. Found in the Carnatic, burrows in the ground for $1\frac{1}{2}$ feet or so—[Hab. also Ceylon].

(6879) *Pyxicephalus pluvialis*,—n. s. Nearly allied to the last; differs in its shorter thicker form, and shorter limbs; light greenish fawn, with dark marbling. Length of one $2\frac{3}{10}$ths; hind leg $2\frac{4}{10}$ths; feet $\frac{8}{10}$ths. Dr. Jerdon only procured this during the monsoon in the Carnatic. It is very different in appearance, though with so few essential distinctions, and the natives give a distinct name to each.

(6880) *Pyxicephalus rufescens*,—n. s. Of a rufous colour above, whitish beneath; body rough and granulose; limbs barred. Length $1\frac{1}{2}$ inch; hind leg $2\frac{1}{10}$th; foot $\frac{6}{10}$ths. Not rare in gardens on the Malabar Coast.

(6881) *Engystoma ornatum*. Some specimens of this very handsome frog were only once procured by Walter Elliot, Esq. on the Neilgherries. Length $1\frac{4}{10}$th inch.; hind leg $1\frac{6}{10}$ths; foot $\frac{11}{20}$th.

(6882) *Engystoma rubrum*,—n. s. Indian red above; some black marks on the legs. Length $1\frac{1}{10}$th inch; hind leg $1\frac{5}{10}$th; foot $\frac{5}{10}$th. Found in the Carnatic near rivers, in sandy banks. [Also Ceylon.—*Cur. As. Soc*].

(6883) *Engystoma malabaricum*,—n. s. Isabella colour above, varied with dark angular markings; sides dark purplish; throat ditto; limbs barred. Length $1\frac{1}{10}$th; hind leg $1\frac{6}{10}$th; foot $\frac{5}{10}$th. Found in Malabar, under stones.

(6884) *Engystoma carnaticum*,—n. s. Nearly allied to the last, differs in the shorter muzzle, shorter hind leg, &c. Length $\frac{8}{10}$ths of an inch: hind leg $1\frac{1}{10}$th; foot $\frac{4}{10}$ths. Found in the Carnatic during the monsoon.—*Jerdon.*

The following notices and descriptions, are by Mr. Blyth, of various Reptiles, new or little known.

(6885) *Calamaria Catenata*, Blyth *n. s.* (*C. monticola*? Cantor, P.Z.S. 1839, p. 50). [" *C. olivaceo fusca, collari, læte flavo, linea dorsali albicante, abdomine citrino. Scut. abd* 125; *scutel. subcaud.* 44. Hab. Naga Hills."] No anterior frontals: the vertical plate broad, pentagonal, and almost as large as the occipitals: 13 rows of scales: scutæ 187; scutellæ 41 pairs. Predominant colour dusky above, formed by minute black specks upon a pale ground-tint; below pale buff with an iridescent lustre, and marked with lateral series of square black spots chiefly upon alternate scutæ. Four black lines throughout above, the upper bordering a pale medial streak, which is simple upon the tail, but along the body forms a concatenation of elongated oval spots. An imperfect whitish-buff collar, and similar marks before and behind the eye. Length of specimen 17 in., of which tail $2\frac{1}{2}$ in. From Assam. Mr. Robinson. [This and other species sent by Mr. Robinson, we much suspect are from the Khasya hills, or other uplaud territory.]

(6886) *Calamaria reticulata*, Blyth *n. s.* Vertical plate hexagonal, angulated to the front, and not half so large as the occipitals: supra-orbital and subtriangular. Thirteen rows of scales: large scutæ 136, 138; scutellæ 27, 28 pairs. Colour shining dull black, brilliant and iridescent below: minute yellowish-white specks on the sides of the mouth, throat, and along the sides of the body. In spirit, the edges of the scales are seen to be of a deep black, imparting a reticulated appearance. The larger of two specimens measures 12 in., of which tail $2\frac{5}{8}$ in. From Assam. Mr. Robinson.

(6887) *Calamaria tenuiceps*, Blyth *n. s.* Colour iridescent. black above, yellowish-white below. Nearly affined to C. longiceps, Cantor, but the head anterior to the eyes much less elongated, and the posterior frontals consequently are about as broad as long: vertical plate elongate-hexangular, broadest anteriorly: head conical, narrow; the jaws of equal length. Thirteen rows of scales. Scutæ 138; scutellæ 37 pairs. Length of specimen 14 in., of which tail 2 in. From the vicinity of Darjiling. Capt. W. S. Sherwill. The two following species of this genus are remarkable for having the posterior frontals united.

(6888) *Calamaria fusca*, Blyth *n. s.* Of an iridescent dull black colour throughout, the ventrals slightly margined paler. Head small, narrow. Vertical plate pentangular with rounded anterior base, the posterior lateral angles so obtuse in some that the plate might then be described as triangular: occipitals very large, elongated. Thirteen rows of scales. Scutæ 155-7; scutellae 30-34 pairs. Length 15 in., of which tail 2 in. Young obscurely striated with longitudinal rows of pale dots. From Darjiling. Capt. W. S. Sherwell.

(7889) *Calamaria obscuro-striata*, Blyth *n. s.* Much affined to last: the muzzle less obtusely pointed, and the anterior frontals conspicuously smaller. Iridescent brown-black, the under-parts particularly lustrous: obscurely streaked throughout with a pale band occupying the adjoining portions of the fourth and fifth rows of scales on each side, a narrow pale line also along the middle of each of the first three rows, and three similar narrow pale lines along the back, all alternating with dusky lines. Thirteen rows of scales. Scutæ 153-163: scutellæ 40 pairs. Length of the large of two specimens $11\frac{1}{4}$ in., of which tail 2 in. From Rangoon. The next has both the anterior and the posterior frontals, respectively, united or undivided.

(6890) *Calamaria bicolor*, Blyth *n. s.* Dusky-plumbeous above, buffy-white below, throughout; these colours gradually blending, and not abruptly demarcated as in C. tenuiceps. Vertical plate pentangular, broader than long, or forming almost a triangle laterally truncated: nostral large and broad; the muzzle consequently obtuse; and the head broader and flatter than usual in this genus. Seventeen rows of scales. Scutæ 210;

scutellæ 75 pairs. Length of a specimen 19½ in., of which tail 4⅜ in. From Assam. Mr. Robinson.

(6891) *Coronella callicephalus*, Gray, *Ann. M. N. H.*, Dec. 1853, p. 390. [When the above description was taken, we had not seen that by Mr. Gray, which is less detailed.] A beautiful species, with form and scutation of head as in the European Coluber Esculapei (as figured by Schlegel); but the eye somewhat smaller. Nineteen rows of scales: scutæ 201, 211; scutellæ 56, 65 pairs. Colour a light brown, paler below. Head with a median black line over the vertical and occipital scutæ, and another continued from each eye to the first of a series of about 18 semi-annuli, which in the young consist of large and broad white-edged black spots, reaching down to the abdominal scutæ; but in adults the black of the interior of these spots disappears more or less completely, leaving only the pale-margined black edge, so that two narrow black transverse bands remain in place of the single broad black spot of the young: also at about the ninth or tenth of the latter from the head, two narrow black dorsal lines commence, which at first are broken and irregular, but gradually become continuous and well defined towards and upon the tail, where they cross its transverse bands and are continued to the extreme tip. Length of a specimen 27 in., of which tail 4 in. From Assam. Mr. Robinson.

(6892) *Xenodon Purpurascens*, Schlegel. The varieties of colouring of this Snake are extraordinary; even more so than those of Lycodon Aulicus. Two adults in spirit from Goalpara are entirely of a pale colour (evidently, however, much blanched), *without traces of markings*. Another, from Assam, is of a dull red-brown above, with narrow black transverse bands; lower-parts reddish-pearly, with two rows of somewhat indistinct black spots, mostly on alternate *scutæ*: head-markings indistinct. A third variety (*Coronella albocincta*, Cantor. *P. Z. S.* 1839, p. 50), also from Assam, is of a clay colour, the scales black-margined and sprinkled over with minute black spots, and the entire length marked with about 24 black-edged white semi-annuli; beneath, the black spots are more developed than in the last variety, and are more or less continuous towards the vent: the usual head markings distinct. Two others from Goalpara and Lower Assam, nearly resemble the last, but have no white semi-annuli, nor markings underneath the tail or anterior third of body. Others, again, from various parts, including central [Ammerkantak, towards source of Nerbudda; 3700 ft. elevation.] and S. India and Ceylon, also the Tenasserim provinces, have the upper-parts more or less dark, and variously freckled, often with imperfect semi-annuli placed near together, and alternately distinct and comparatively obscure: the under-parts commonly spotless; and sometimes the collar quite black. A single young specimen from Ceylon has 3 rows of black spots continued upon each scuta as far as the vent, where the medial row ceases, and the other two rows are continued to the tip of the tail: above, the black semi-annuli are divided, and the halves placed alternately to the right and left, becoming gradually indistinct upon the hinder half Upon a first view, this might be considered a distinct species; but we can perceive no structural variation from the rest, and intermediate varieties most probably occur. In all, save the first, the peculiar markings of the head readily indicate the species; as do the rostral and anterior frontal plates from other Indian serpents.

(6893) *Coluber nigromarginatus*, nobis, *n. s.* Nearly allied to C. radiatus, Schlegel, but attaining the size of C. mucosus, (L., v. *Blumenbachii*. Merrem): our largest specimen measuring 7¾ ft. long, of which the tail is 2. ft. 1 in. Colour a bright pea-green (changing in spirit to blue), paler below, each scale of the upper-parts margined with black. Upon the shields of the crown the black margins are extremely slight though present, and they gradually increase in breadth posteriorly until about the middle of the entire length, when the two colours resolve into four black alternating with three narrower blue streaks which are continued to the end of the tail. Eye larger than in C. mucosus, much larger than in C. radiatus. One large superior and one small inferior præ-ocular plate; and a single frænal, the latter as in C. radiatus, to which the present species bears a near approximation in the details of its structure. Sixteen rows of scales, the four median slightly carinated. Scutæ 192-4; scutellæ 126-132 pairs. Hab. Vicinity of Darjiling, where procured by Capt. W. S. Sherwill, who sent with it examples of C. radiates, C. korros, and C. fasciolatus. Dr. Kelaart has also favoured us with C. korros from Ceylon; but the species does not appear to have been hitherto observed in the Indian peninsula.

(6894) *Coluber Prasinus*, Blyth, *n. s.* Wholly green, becoming verditer in spirit; glaucous below and bordering the mouth: 19 rows of slightly carinated scales: scutæ 205, 6; scutellæ 107, 8 pairs Vertical shield triangular with rounded apex; rather larger than the supra-orbitals, and rather smaller than the occipitals: a single large præ-orbitals, and one elongate-oval frænal. Tail suddenly tapering. The larger of two specimens measures 37 in., of which tail 9 in. From Assam. Mr. Robinson.

(6895) *Coluber Hexagonotus* (?), Cantor, [*J. A. S.* XVI, 921.] var. adult. Length 4 ft., of which tail 15½ in.; the latter remarkably slender. Colour brown, paler below; the anterior fourth of the body marked with transverse dusky bands, which become gradually more obscure till they disappear. Seventeen rows of

(6879) *Pyxicephalus pluvialis*,—n. s. Nearly allied to the last; differs in its shorter thicker form, and shorter limbs; light greenish fawn, with dark marbling. Length of one 2 2/10ths; hind leg 2 4/10ths; feet 8/10ths. Dr. Jerdon only procured this during the monsoon in the Carnatic. It is very different in appearance, though with so few essential distinctions, and the natives give a distinct name to each.

(6880) *Pyxicephalus rufescens*,—n. s. Of a rufous colour above, whitish beneath; body rough and granulose; limbs barred. Length 1½ inch; hind leg 2 1/10th; foot 6/10ths. Not rare in gardens on the Malabar Coast.

(6881) *Engystoma ornatum*. Some specimens of this very handsome frog were only once procured by Walter Elliot, Esq. on the Neilgherries. Length 1 4/10th inch.; hind leg 1 6/10ths; foot 1/20th.

(6882) *Engystoma rubrum*,—n. s. Indian red above; some black marks on the legs. Length 1 1/10th inch; hind leg 1 4/10th; foot 1/10th. Found in the Carnatic near rivers, in sandy banks. [Also Ceylon.—*Cur. As. Soc*].

(6883) *Engystoma malabaricum*,—n. s. Isabella colour above, varied with dark angular markings; sides dark purplish; throat ditto; limbs barred. Length 1 1/10th; hind leg 1 6/10th; foot 5/10th. Found in Malabar, under stones.

(6884) *Engystoma carnaticum*,—n. s. Nearly allied to the last, differs in the shorter muzzle, shorter hind leg, &c. Length 6/10ths of an inch: hind leg 1 1/10th; foot 4/10ths. Found in the Carnatic during the monsoon.—*Jerdon.*

The following notices and descriptions, are by Mr. Blyth, of various Reptiles, new or little known.

(6885) *Calamaria Catenata*, Blyth *n. s.* (*C. monticola*? Cantor, P.Z.S. 1839, p. 50). [" *C. olivaceo fusca, collari, læte flavo, linea dorsali albicante, abdomine citrino. Scut. abd* 125; *scutel. subcaud.* 44. Hab. Naga Hills."] No anterior frontals: the vertical plate broad, pentagonal, and almost as large as the occipitals: 13 rows of scales: scutæ 187; scutellæ 41 pairs. Predominant colour dusky above, formed by minute black specks upon a pale ground-tint; below pale buff with an iridescent lustre, and marked with lateral series of square black spots chiefly upon alternate scutæ. Four black lines throughout above, the upper bordering a pale medial streak, which is simple upon the tail, but along the body forms a concatenation of elongated oval spots. An imperfect whitish-buff collar, and similar marks before and behind the eye. Length of specimen 17 in., of which tail 2½ in. From Assam. Mr. Robinson. [This and other species sent by Mr. Robinson, we much suspect are from the Khasya hills, or other upland territory.]

(6886) *Calamaria reticulata*, Blyth *n. s.* Vertical plate hexagonal, angulated to the front, and not half so large as the occipitals: supra-orbital and subtriangular. Thirteen rows of scales: large scutæ 136, 138; scutellæ 27, 28 pairs. Colour shining dull black, brilliant and iridescent below: minute yellowish-white specks on the sides of the mouth, throat, and along the sides of the body. In spirit, the edges of the scales are seen to be of a deep black, imparting a reticulated appearance. The larger of two specimens measures 12 in., of which tail 2⅝ in. From Assam. Mr. Robinson.

(6887) *Calamaria tenuiceps*, Blyth *n. s.* Colour iridescent. black above, yellowish-white below. Nearly affined to C. longiceps, Cantor, but the head anterior to the eyes much less elongated, and the posterior frontals consequently are about as broad as long: vertical plate elongate-hexangular, broadest anteriorly: head conical, narrow; the jaws of equal length. Thirteen rows of scales. Scutæ 138; scutellæ 37 pairs. Length of specimen 14 in., of which tail 2 in. From the vicinity of Darjiling. Capt. W. S. Sherwill. The two following species of this genus are remarkable for having the posterior frontals united.

(6888) *Calamaria fusca*, Blyth *n. s.* Of an iridescent dull black colour throughout, the ventrals slightly margined paler. Head small, narrow. Vertical plate pentangular with rounded anterior base, the posterior lateral angles so obtuse in some that the plate might then be described as triangular: occipitals very large, elongated. Thirteen rows of scales. Scutæ 155-7; scutellae 30-34 pairs. Length 15 in., of which tail 2 in. Young obscurely striated with longitudinal rows of pale dots. From Darjiling. Capt. W. S. Sherwell.

(6889) *Calamaria obscuro-striata*, Blyth *n. s.* Much affined to last: the muzzle less obtusely pointed, and the anterior frontals conspicuously smaller. Iridescent brown-black, the under-parts particularly lustrous: obscurely streaked throughout with a pale band occupying the adjoining portions of the fourth and fifth rows of scales on each side, a narrow pale line also along the middle of each of the first three rows, and three similar narrow pale lines along the back, all alternating with dusky lines. Thirteen rows of scales. Scutæ 153-163: scutellæ 40 pairs. Length of the large of two specimens 11¼ in., of which tail 2 in. From Rangoon. The next has both the anterior and the posterior frontals, respectively, united or undivided.

(6890) *Calamaria bicolor*, Blyth *n. s.* Dusky-plumbeous above, buffy-white below, throughout; these colours gradually blending, and not abruptly demarcated as in C. tenuiceps. Vertical plate pentangular, broader than long, or forming almost a triangle laterally truncated: nostral large and broad; the muzzle consequently obtuse; and the head broader and flatter than usual in this genus. Seventeen rows of scales. Scutæ 210;

scutellæ 75 pairs. Length of a specimen 19½ in., of which tail 4⅜ in. From Assam. Mr. Robinson.

(6891) *Coronella callicephalus*, Gray, *Ann. M. N. H.*, Dec. 1853, p. 390. [When the above description was taken, we had not seen that by Mr. Gray, which is less detailed.] A beautiful species, with form and scutation of head as in the European Coluber Esculapei (as figured by Schlegel); but the eye somewhat smaller. Nineteen rows of scales: scutæ 201, 211; scutellæ 56, 65 pairs. Colour a light brown, paler below. Head with a median black line over the vertical and occipital scutæ, and another continued from each eye to the first of a series of about 18 semi-annuli, which in the young consist of large and broad white-edged black spots, reaching down to the abdominal scutæ; but in adults the black of the interior of these spots disappears more or less completely, leaving only the pale-margined black edge, so that two narrow black transverse bands remain in place of the single broad black spot of the young: also at about the ninth or tenth of the latter from the head, two narrow black dorsal lines commence, which at first are broken and irregular, but gradually become continuous and well defined towards and upon the tail, where they cross its transverse bands and are continued to the extreme tip. Length of a specimen 27 in., of which tail 4 in. From Assam. Mr. Robinson.

(6892) *Xenodon Purpurascens*, Schlegel. The varieties of colouring of this Snake are extraordinary; even more so than those of Lycodon Aulicus. Two adults in spirit from Goalpara are entirely of a pale colour (evidently, however, much blanched), *without traces of markings*. Another, from Assam, is of a dull red-brown above, with narrow black transverse bands; lower-parts reddish-pearly, with two rows of somewhat indistinct black spots, mostly on alternate *scutæ*: head-markings indistinct. A third variety (*Coronella albocincta*, Cantor. *P. Z. S.* 1839, p. 50), also from Assam, is of a clay colour, the scales black-margined and sprinkled over with minute black spots, and the entire length marked with about 24 black-edged white semi-annuli; beneath, the black spots are more developed than in the last variety, and are more or less continuous towards the vent: the usual head markings distinct. Two others from Goalpara and Lower Assam, nearly resemble the last, but have no white semi-annuli, nor markings underneath the tail or anterior third of body. Others, again, from various parts, including central [Ammerkantak, towards source of Nerbudda; 3700 ft. elevation.] and S. India and Ceylon, also the Tenasserim provinces, have the upper-parts more or less dark, and variously freckled, often with imperfect semi-annuli placed near together, and alternately distinct and comparatively

obscure: the under-parts commonly spotless; and sometimes the collar quite black. A single young specimen from Ceylon has 3 rows of black spots continued upon each scuta as far as the vent, where the medial row ceases, and the other two rows are continued to the tip of the tail: above, the black semi-annuli are divided, and the halves placed alternately to the right and left, becoming gradually indistinct upon the hinder half. Upon a first view, this might be considered a distinct species; but we can perceive no structural variation from the rest, and intermediate varieties most probably occur. In all, save the first, the peculiar markings of the head readily indicate the species; as do the rostral and anterior frontal plates from other Indian serpents.

(6893) *Coluber nigromarginatus*, nobis, *n. s.* Nearly allied to C. radiatus, Schlegel, but attaining the size of C. mucosus, (L., v. *Blumenbachii*. Merrem): our largest specimen measuring 7¾ ft. long, of which the tail is 2. ft. 1 in. Colour a bright pea-green (changing in spirit to blue), paler below, each scale of the upper-parts margined with black. Upon the shields of the crown the black margins are extremely slight though present, and they gradually increase in breadth posteriorly until about the middle of the entire length, when the two colours resolve into four black alternating with three narrower blue streaks which are continued to the end of the tail. Eye larger than in C. mucosus, much larger than in C. radiatus. One large superior and one small inferior præ-ocular plate; and a single frænal, the latter as in C. radiatus, to which the present species bears a near approximation in the details of its structure. Sixteen rows of scales, the four median slightly carinated. Scutæ 192-4; scutellæ 126-132 pairs. Hab. Vicinity of Darjiling, where procured by Capt. W. S. Sherwill, who sent with it examples of C. radiates, C. korros, and C. fasciolatus. Dr. Kelaart has also favoured us with C. korros from Ceylon; but the species does not appear to have been hitherto observed in the Indian peninsula.

(6894) *Coluber Prasinus*, Blyth, *n. s.* Wholly green, becoming verditer in spirit; glaucous below and bordering the mouth: 19 rows of slightly carinated scales: scutæ 205, 6; scutellæ 107, 8 pairs. Vertical shield triangular with rounded apex; rather larger than the supra-orbitals, and rather smaller than the occipitals: a single large præ-orbitals, and one elongate-oval frænal. Tail suddenly tapering. The larger of two specimens measures 37 in., of which tail 9 in. From Assam. Mr. Robinson.

(6895) *Coluber Hexagonotus* (?), Cantor, [*J. A. S.* XVI, 921.] var. adult. Length 4 ft., of which tail 15½ in.; the latter remarkably slender. Colour brown, paler below; the anterior fourth of the body marked with transverse dusky bands, which become gradually more obscure till they disappear. Seventeen rows of

slightly imbricated scales, the median row hexagonal. Vertical plate large, pentagonal, broad to the front. Two præ-orbitals, the lower small and bordered by the third and fourth labials; the fourth labial bordering the eye, which is of moderate size; two post-orbitals, and a third or infra-orbital bordering on the fourth, fifth, and sixth labials: nasals large, elongate, the nostril opening in the middle, near the outer border of the anterior frontal; a single small subtriangular frænal. Scutæ 195; scutellæ 144 pairs. Hab. Arakan (Ramri)?

(6896) *Coluber diadema*, Schlegel; *C. Oppelii*, Wagler. This is a little known species; and two examples of it in Calcutta museum (origin uncertain) would not be readily recognised from Russell's plate (II, 30), which would appear to have been taken from an old and remarkably thick individual. One of the Society's specimens is of about equal length to that figured by Russell, but is much more slender; the other is smaller. The markings of the head are very peculiar, as the transverse black band from eye to eye and continued below the eye, and the four black specks on the two occipital plates. Upon the nape is a longitudinal black stripe, followed by a series of black spots along the spine, the first few of them being round, the rest gradually assuming the appearance of short transverse bands, much more regular and placed nearer together than as represented by Russell: towards the tail they diminish in size, and upon it are reduced to a series of minute black specks. Their number, from head to base of tail, amounts to 75. Alternating with the dorsal bands is, on each side, a series of smaller lateral transverse bands, which begin on the sides of the neck as large round black spots, following two oblique streaks behind the eye, and disappear altogether on the tail. They are placed with great regularity; and on the borders of the abdominal scutæ is a further series of black spots. Such as are the markings of our larger specimens, these being of an unmixed black. In our smaller example, all the dorsal black bands have the middle of each scale marked with the pale clay-colour which constitutes the general ground-tint, the lateral streaks are less decided, but the spots on the borders of the scutæ are more so, and every alternate scuta has an additional spot near each lateral margin. There are 19 rows of perfectly smooth (or not carinated imbricated scales. Eye rather large: a great upper and small lower præ-orbital; one large subquadrate frænal; two post-orbitals: and the fifth and sixth labials border the eye below. Scutæ 297-8; scutellæ 98 pairs. Length of our larger specimen 36½ in., of which tail 9¼ in.

(6897) *Coluber pictus*, Daudin; *C. Plinii*, Merrem (Russell, I, 29). Of this little known species, Mr. Jerdon has favoured us with a young example, from S. India. It is a true Coluber, and not a variety of Coronella baliodeira, Schlegel, as suspected by Dr. Cantor. [*J. A. S.* XVI, 913.]

(6898) *Herpetodryas helena*, (Daudin). In the Society's museum are two specimens of a Snake, from Darjiling and Rungpore respectively, which may represent a variety of this species. Colour nearly uniform brown above, yellowish-white below with two lateral rows of dusky specks, one speck on each side of every abdominal scuta; a slight dusky streak from behind the eye; a trace of a black V-like mark on the nape; and very obscure indications of body-markings analogous to those of Russell's figure (I, 32) Seventeen rows of carinated scales. The larger of two individuals measures 29½ in., of which the tail occupies 8 in., and head 1 in. Scutæ 189, 199; scutellæ 84, 90.

(6899) *Psammophis condanarius*, Gray (Russell, I, pl. 27; very bad.) Seventeen rows of smooth scales, of which the first row on each side is very broad, the second row less broad, and the rest narrow and lanceolate. General colour bright green above, pale yellow or yellowish white below; longitudinally striped, except more or less towards the head, with four pale bands: the upper occupying the fourth and half respectively of the third and fifth rows of scales, and bounded above and below with a more or less defined narrow black line; the lower occupying the lateral margins of the abdominal scutæ and subcaudal scutellæ, and defined above and below with narrow black lines which are very distinct. A pale superciliary streak bordered with black commences from the nostrils, and another below the eye, occupying the upper half of the labials. Some also shew an ill-defined pale dorsal streak. Hab. Lower Bengal?

(6900) *Leptophis rubescens; Dipsas rubescens*, Gray, Hardwicke's *Ill. Ind. Zool.* This seems affined to Dendrophis Rhodopleuron, Schlegel, from Amboyna. The areal apertures are remarkably minute and abruptly pierced in the centre of the nasals. Vertical plate narrow. Neck slender. Body much compressed. General aspect of colour reddish-brown, powdered over throughout, excepting on the chin and throat, with minute specks. A row of black spots along the spine. A brown central occipital stripe, and similar lateral stripe from nostril to ear. Seventeen rows of smooth scales. Scutæ 198; scutellæ 120. From Mergui. Capt. Berdmore.

(6901) *Leptophis ornatus*, (Shaw), var. Marked very like young specimens of Coronella Russellii, excepting on the head. Colour olive-grown, the upper-parts marked throughout with a regular series of transverse black bars, broader towards the head, narrower and becoming indistinct towards the end of the tail; these black bars set off by whitish edges. Head marked nearly as usual. From Ceylon. Dr. Kelaart.

(6902) *Dipsas ferruginea*, Cantor, *P. Z. S.* 1839, p. 53. Head smooth and flat above, remarkably Frog-like, with somewhat pointed muzzle; anterior frontals very small; the supra-orbitals larger than the vertical plate. Canines above and below well developed. Tail suddenly tapering. Colour a dull somewhat ferruginous brown above, a little marked with black and white shewing between the scales; a broad dark lateral band throughout, and above it an obscure pale band: lower-parts buffy yellowish-white, with a narrow dark lateral band on each side, and the rest thickly sprinkled over with minute black specks. Head with a narrow black median line over the frontal and vertical plates, and another over the supra-orbital, meeting its opposite on the occipital and continued to the nape: black lines also border the lips and pass through the eye. Seventeen rows of scales: scutæ 171, 175; scutellæ 56, 64 pairs. Length of one 18¾ in., of which tail 3¼ in. From Assam and the vicinity of Darjiling; Mr. Robinson and Capt. Sherwill.

(6903) *Dipsas Monticola*, Cantor, *P. Z. S.* 1839, p. 53. Affined to *D. Trigonota* in structure. Brown above, pearly-white below, separated by a broad black streak behind the eye: lowermost row of scales black-bordered for the anterior third of the body; and traces of other lines towards the head. Fifteen rows of scales: scutæ 158, 193; scutellæ 82, 106 pairs. Length of one 22 in., of which tail 7¼ in. Hab. Assam; Mr. Robinson.

(6904) *Dipsas Nigromarginata*, Blyth, *n. s.* Also affined to *D. Trigonota*, with median row of dorsal scales broad and hexagonal. No elongated teeth. Colour throughout green above, the distensible skin black between the scales; yellowish-white below. Twenty-one ranges of scales; scutæ 252; scutellæ 132 pairs. Length of one 42 in., of which tail 11 in. Hab. Assam. Mr. Robinson.

(6905) *Dipsas Trigonota*, the most common species of India proper, attains to about 6 ft. in length, but is rarely met with so large, and preys (at least those of medium size) chiefly on the Calotes versicolor in L. Bengal. Vertical shield as broad as in the Malayan D. Multimaculata, not less so as represented in Dr. Schlegel's plate. The markings are ill represented by Russell, who figures the young. The very young (about 9 in.) are of a pale ashy colour, with but slight traces of the markings of the adult; a faint lateral band consisting of three parallel somewhat darker lines is continued throughout the length, also a medial and two lateral abdominal lines, besides which the under-parts are very minutely speckled. There is a white median frontal streak bordered with black, continued into a black occipital streak. When 2 or 3 ft. long, the white frontal streak is retained, and at the occiput

are two diverging white lines, which converge and meet behind at the first of the series of imperfectly triangular white spots bordered and set off with black, which are continued throughout the body; becoming gradually more ill defined towards and upon the tail. The lower-parts are now pearly-white, a trace only of the lateral abdominal lines appearing as a row of small spots on each side, though not regularly upon every scuta. The full grown adults is altogether much darker, with the white markings tending to become obsolete; a conspicuous median black stripe is continued over the forehead and occiput, and another proceeds backwards from each eye. Abdomen more or less speckled, with the lines of lateral spots more or less apparent.

(6906) *Tropidonotus zebrinus*, Blyth, *n. s* (*Tr. chrysargos* Schlegel, var. ?) Vertical plate twice as broad as the superciliary, and of same length. One præ-orbital and three postorbitals. Upper-parts (in spirit) deep plumbeous, obscurely spotted with black; the sides and under-parts yellowish-white, the former throughout banded with black, and each band having a whitish spot (probably yellow in the recent specimen) above it. Head plumbeous above, the labial plates with a triangular black spot at the point of junction of each of them above and exhibiting thus two larger spots posterior and two smaller anterior to the eye. Two or three distinct black bands across the nape. Rows of scales 15: scutæ 137; scutellæ 96 pairs. Length of specimen (which is quite young) 10⅜ in., of which the tail measures 8½ in. From Mergui. Capt. Berdmore.

(6907) *Tropidonotus angusticeps*, Blyth, *n. s.* Head narrow, not broader than the neck, little depressed, the eye much larger than in *Tr. subminiatus*, and vertical shield broad. Colour (in spirit) plumbeous above, uniformly spotted with black throughout; below whitish, more or less variegated with black on the hinder half: head without markings; but a V-like mark on the nape with apex towards the occiput, becoming obsolete in adults. One specimen has 4 præ-orbital and 5 post-orbital plates; but in general these number 2 or 3 and 4: and same specimen is remarkable for having no dark markings above, but some indistinct pale spots, probably of a vivid colour on the recent Snake. In an adult the black spots on the upper parts are almost confined to the skin between the scales, and there is no blackish colour on the hinder half underneath. Seventeen rows of scales: scutæ 167, 72; scutellæ 57, 67 pairs. Length of an adult 41 in., of which tail 8½ in. Inhabits Assam and Arakan.

(6908) *Tropidonotus Subminiatus* (?), Schlegel. A mostvariable species, affined in structure to the preceding. One 16 in. long has the upper-parts speckled over with black and bright yellow on a greenish ground, under-parts whitish throughout. Head plumbeous above: a large black patch be-

hind the occiput, surrounded except in front by orange-yellow border, behind which again the nape is bright vermillion, chiefly between the scales. A conspicuous black streak below the eye, and two black spots posteriorly towards the gape: scutæ 147 ; scutellæ 94 pairs. Another rather larger, has the back almost plain dark plumbeous, paler and spotted with black towards the nape ; lower-parts freckled with minute black specks, and increasingly so to the tail-tip : occiput and nape green, crossed with two orange bands, becoming redder posteriorly. All the upper labials with a black stripe, where each adjoins the next. Scutæ 157 ; scutellæ 66 pairs. A third, 29 in. long, has the upper-parts dark olive brown, with bright yellow spots on the skin between the scales ; the lower dull pearly : nape green, followed by a vermillion space : a single broad black streak below the eye. Scutæ 155 ; scutellæ 83 pairs. The above three specimens are from Assam. Numerous others from Rungpore and Arakan, are mostly similar to the last, with generally a double black streak below the eye uniting beneath, rarely a single streak, and one large specimen has no streak below the eye : this would seem to disappear with age. Rows of scales 17, 19 : scutæ 150, 166 ; scutellæ 60 to 90 pairs, but generally intermediate. Tail in all suddenly tapering. Largest specimen, which is much thicker than the others (denoting maturity), 3 ft., of which tail 8½ in.

(6909) *Tropidonotus macrops*, Blyth *n. s.* Eye very large ; the vertical shield broad, and posterior frontals twice as large as the anterior. Prevailing hue of the upper-parts a dull vinaceous : many of the scales margined with black, and some with yellow : a series of yellow spots (about 50 in number) continued along the spine to the extremity of the tail, with a row of black spots on either side. Head and neck plumbeous diverging on the nape where the first of the series of yellow spots is placed ; a slight whitish V-like mark in occiput. Lower parts yellowish-white, with specks and powdering of dusky ; more prevalent towards and upon the tail. Seventeen ranges of scales : scutæ 164-6 ; scutellæ 130-46 pairs Length of largest specimen 31 in., of which tail 6¼ in. Two specimens closely resemble, but a third presents some differences of colour. The row of yellow spots is wanting along the spine, also the dark band on the nape, and the pale V-like occipital mark : the under-parts also are more uniformly whitish. Scutæ 168 ; scutellæ 124 pairs only. All are from near Darjiling. Capt W. S. Sherwill.

(6910) *Tropidonotus dipsas*, Blyth, *n. s.* Form as in *dipsas*, slender : the neck much compressed. Head oval, flattened above ; eyes large ; the muzzle anterior to the orbits short : nostrils small, opening quite laterally ; the nasal and rostral shields being vertical. General colour plumbeous above, obscurely spotted with black, and two barel traceble lines of whitish spots, more distinct to wards and upon the neck where they increase i size towards the head. Occiput black, with an elon gated white medial spot, and white V-like mar behind it, the apex of which is prolonged a littl backward. A narrow black line from eye to ey passing in front towards the muzzle ; and broade black streak posterior to the eye, continued as series of longish oval spots on the sides of th neck bordering the scutæ. Some black mark also on the upper labials. Under-parts whit throughout, with a row of minute black specks o either side. Rows of scales 17 : scutæ 169 scutellæ 99 pairs. Specimen (young) 21½ i long, of which tail 4¼ in. Vicinity of Darjiling Capt. W. S. Sherwill.

(6911) *Tropidonotus Platyceps*, Blyth, *n. s.* A beautiful species, with small and flat (but not broad head, having much the aspect of a Herpetodryas (Perhaps H. Frænatus, Gray, (*Ann. M. N. H.* Dec. 1853, p. 391,) may prove to be a variety. Young specimens generally shew the two whit dots on the occipital shields, seen also in Tr UMBRATUS. Frontal and nasal shields vertical Head and upper-parts deep green with slightl black-edged scales ; the lower-parts brigh yellow, with a coral-red stripe bordering th abdominal scutæ on each side, and strongl tinging the sides of the body : subcaudal scutella variegated with greenish-dusky, and traces o the same about the throat. A white streal bordered with black passes backward from be hind the eye and then upward to the occiput, bu this would seem to disappear with age. Suc is (or was) the colouring of two specimens re spectively 27 in. long (of which tail 8 in.), an 21½ in. (of which tail 6⅛ in.). But another 21½ in. long, is remarkable for having the chi and throat quite black, also the black marking of the dorsal scales more strongly developed tha in the others, and the black marblings of the sub caudal scutellæ are more intense : the latera coral-red band is merely indicated ; and th white streak behind the eye is more strongl developed and continued forward to the muzzle Number of rows of scales 19 : scutæ 174, 86 scutellæ 89, 99 pairs. Another, from Assam appears identical, but has 155 scutæ only ; an in spirit appears of a dull olive-green colour, wit two longitudinal pale ruddy dorsal stripes, muc as in Tr. stolatus, and the lower-parts ar marked throughout with a black lateral spo on each scuta, seen also in the black-throate specimen. A small young example from th Khasya hills is similar to that from Assam. Th three first described are from near Darjiling. Cap W. S. Sherwill.

(6912) *Elaps Personatus*, Blyth, *n. s.* Vertica plate about equal to the posterior frontals supra-orbitals large, subquadrangular, elongate Colour of upper-parts bright red in the adult

brown or reddish-brown in the young; marked throughout with from 22 to 38 narrow black semi-annuli, having slight whitish margins: under-parts dull yellowish-white, mottled throughout with black patches more or less developed; head black above, with whitish muzzle and broad cross band posterior to the eyes. Scales lustrous; 13 rows above: scutæ 196, 218; scutellæ 29, 34 pairs. Length of largest specimen 24¼ in., of which tail 2¾ in. From Assam.

(6913) *Rana Robusta*, Blyth, *n. s.* A moderately large Frog from Ceylon. Limbs exceedingly thick and massive; the third-digits fully webbed. Skin subgranulose, especially on the lower-parts. A slight transverse fold on the breast. Colour dusky above, with a large black patch on the back another on the croup, and smaller lateral patches. Lower parts yellowish-white, with a V-like mark on the lower surface of the thigh in one of two specimens, both males. The same individual has dusky spots or imperfect streaks on the lower surface of the thigh, and its posterior surface is marked with longitudinal streaks of alternating black and yellowish-white. Digital membrane speckled with black. Length from snout to vent 3 in., and of hind-limb 4 in., of which the foot is half. Presented by Dr. E. F. Kelaart.

(6914) *Lymnodytes maculatus*, Blyth, *n. s.* Differs from L. erythræus by the slightly but distinctly papillose skin of the back, and non-verrucose posterior surface of thighs; by its shorter and stouter limbs, and short anterior digits, the two outermost of which have their terminal disks smaller than in L. erythræus. There is a broad black band from nostril to loin, bordered above and below by narrow pale yellow streaks. Entire lower-parts spotless light yellow, as also the upper lip. A black spot at the shoulder, and line along the posterior surface of the four-limb. One or more similar lines on the hind-limbs; the thighs beautifully mottled with black; and a black medial line along the back, which becomes double over the loins. Length of male from muzzle to vent 2⅜ in.; of hind-limb 3¾ in.; of which the foot measures 1¾ in. Hab. Ceylon. Dr. E. F. Kelaart.

(6915) *Lymnodytes lividus*, Blyth, *n. s.* A large species with short and remarkably fleshy thighs. Colour dusky above, paler and tinged with ruddy on the sides which are spotted with black. Chin, throat and breast, minutely variegated pale and dusky. Belly and thighs underneath, sullied whitish. Above, the thighs and shanks are paler than the back and tinged with ruddy, having several dusky cross-bands. Posterior surface of thigh smooth or non-verrucose. Length from muzzle to vent 3¼ in., and hind-leg 4½ in., of which the foot is 2¼ in. From Colombo. Dr. E. F. Kelaart.

(6916) *Megalophrys gigas*, Blyth, *n. s.* (Edible Frog of Sikkim, vide *J. A. S.* XXII. 557.) Adult male 4½ in. from snout to vent; hind-foot 7¼ in., of which foot from heel 3⅜ in. Breadth of head 2 in. Interdigital membrane of the hind-foot well developed. Fore-limbs extremely thick, with the skin of their inner surface highly granulose. Upper-parts uniformly dull reddish or purplish black, a little marked with white on the posterior surface of the thigh: below whitish, much suffused with dusky, and some irregular white spots or marblings along the rami of the lower jaw, and also on the sides of the body and along the sides of the limbs. What appear to be the young have the head proportionally less broad than in the adult, and the upper-parts have more of an olive tinge, and the under-parts are ochreous-yellow, mottled with reddish brown. Hab. Sikkim Himalaya. Capt. W. S. Sherwill.

[Two other forms affined to Megalophrys, and like it and Bombinator, exhibiting no external *tympana*, also sent from the Sikkim Himalaya by Capt. Sherwill, we have at present no means of classifying, for want of books of reference.]

(6917) *Bombinator sikimmensis*, Blyth, *n. s.* Size and general character of the European B. igneus. (Laur.), but the hind toes free or slightly webbed only at their extreme base. Male with four large subquadrilateral papillose callosities on the breast, and corresponding callosities on the upper surface of the innermost digits of each fore-foot. The tubercles of the head, body, and limbs, much more developed in males than in females. On the back are four irregular rows of large porous tubercles, and numerous minute tubercles without pores stud the rest of the upper parts. On the hind-limbs small porous tubercles are very regularly disposed. Colour dull livid olive green above, a little banded on the limbs; flame-coloured below more or less marbled with dusky. Presented by Capt. W. S. Sherwill.

(6918) *Homolopsis*. In a collection of snakes from North Carolina presented to the Society by the Rev. F. Fitzerald, through the American Consul, are two fine species of Homolopsis, which do not appear to be described either by Dr. Schlegel, or among the "extralimitals" of New York by M. Dekay, or in other American lists to which we have access. They may, therefore, be here briefly characterized as probably new and undescribed.

(6919) *Homolopsis Reinwardtii*, Schlegel. Form thick and massive, with subtetragonal section; the head broad, subtrigonal, flat, much broader than the neck: body covered with 19 rows of broad, smooth and shining imbricated scales, which on the sides are much larger and broader than upon the back; eyes placed very forward: a single anterior frontal, and series of 7 upper and 9 lower labials. Teeth very minute. Colour black above, yellowish-white below; the sides transversely banded with about 75 bands in all, the black of the back descending and the yellowish-white of the lower parts ascending alternately, and the former continued irregularly across

the lower-parts where the two colours are about equally distributed. Head black, irregularly variegated with yellowish-white: the rostral and labials of the latter hue, and all except the last three inferior labials having a medial black spot. Most of the shields of the chin and throat are also thus spotted. Scutæ 200; scutellæ 37 pairs. Length of specimen 4 ft., of which tail 4 in. Head $1\frac{3}{5}$ in. in greatest breadth.

(6920) *Homolopsis Parviceps*, Blyth. Form moderately thick, attenuating towards the head, which is small and not broader than the neck; body covered with 19 rows of smooth shining imbricated scales, which on the sides are much broader than upon the back; tail with only 8 rows of hexagonal scales besides the scutellæ. Two anterior frontals, half the size of the posterior. Teeth minute. Colour black above, yellowish-white beneath, the latter extending over $2\frac{1}{2}$ rows of scales on either side. Three yellowish-white dorsal stripes, one median extending from the occiput to the middle of the tail, the others lateral and occupying part of the 5th and 6th rows of scales. On the lower parts, also, two lines are formed of broad black spots, one on either side of each scuta, and along the middle of the body is a third and median row. The shields of the head are margined and variegated with yellowish-white, and each labial except the posterior three lower are whitish having a large black spot. Scutæ 161; scutellæ 45. Length of specimen $2\frac{1}{2}$ ft., of which tail $5\frac{1}{2}$ in.

TORTOISES.

(6921) *Testudo Megalopus*. Since the former part of the foregoing paper was published, the author has had an opportunity of shewing the Society's specimens of Burmese Tortoises to the Rev. J. Mason of Maulmein, who has long devoted considerable attention to the zoology of the Tenasserim provinces. This gentleman immediately recognised the Testudo Megalopus (*J. A. S.* XXII, 640,) as the species with which he was most familiar in Burma: at once distinguishing it from the Indian T. Stellata: and as his judgment is worthy of confidence, we may pretty safely now rank T. Megalopus as a third Burmese species of the genus. At about the same date of publication, appeared a paper by Dr. Gray on some undescribed species of reptiles collected by Dr. Joseph Hooker in the Khasia mountains and Sikkim Himalaya. Among them, his genus

(6922) *Dopasia* approximates Blyth's Ophiseps (*J. A. S.* XXII, 655), but is evidently distinct; the position of the vent in Dopasia is not stated.

(6923) *Parias* maculata, Gray, is identical with Trigonocephalus nilgiriensis, Jerdon, *J. A. S.* XXII, 524, as we find upon comparison of a fine Assamese specimen with the description by Messrs. Jerdon and Gray, and with a coloured figure sent by Mr. Jerdon. Mr. Gray does not give the number of rows of scales or of abdominal or caudal plates. Mr. Jerdon writes—"23 rows of carinated scales. Scutæ 142; scutellæ 36." The Asamese specimen has 23 rows of the first; scutæ 143; scutellæ about 36 pairs. Length $14\frac{1}{2}$ in., of which tail barely 2 in. Colour pale, variegated with dark blackish-edged patches on the upper parts, forming irregular transverse bands, more or less divided and the halves alternating; below whitish, the plates speckled laterally with dusky; chin and sides of throat blackish; a whitish band proceeding backward from the eye, another from mouth, and between them a black space. This Asamese specimen has an elongated black occipital spot, succeeded by two lateral streaks which unite posteriorly; a somewhat different arrangement from that in Mr. Jerdon's drawing, and again different from that exhibited in an example from the vicinity of Darjiling, which also has the under-parts much more mottled with black; but all are evidently identical in species.

Further Notices and Descriptions of various Reptiles, new or little known.—By E. Blyth, Esq.

(6924) *Testudo Pkayrei*, Blyth. Great Burmese land Tortoise. Carapax smooth, as in T. RADIATA and T. ANGULATA, but much flatter; oblong; subquadrate, its free marginal plates reverted and moderately serrate. Nuchal plate broader than long. Caudal plate *double*. Gular plates longer than broad, moderately notched: anal broader than long, and deeply notched. Beak unemarginate. Fore-limbs covered with very long and thick imbricated scales, much as in a Pangolin; the claws elongate, strong and thick: similar great elongate scales at the heel; and a group of five principal obtuse spines on either side of the tail, the medial of them remarkably strong and thick. Two or more smaller spines or thick elongate scales above the tail. Colour wholly black, or mingled more or less with buff-yellow. In the young, the scales are probably of the latter hue, with gradually increasing black centres. Limbs deep brown; some of the claws yellow in some specimens; the head and neck paler brown, strongly tinged with yellow. Our largest specimen is 20 in. long in a straight line, or $22\frac{1}{2}$ in. measured over the curve of the carapax, from front of nuchal plate to middle of caudal notch: greatest breadth $14\frac{1}{2}$ in. or $20\frac{1}{2}$ in. following the curve, from one obtuse lateral angle to the other. Height $1\frac{1}{4}$ in. Head to occiput $4\frac{1}{2}$ in. The shell of this individual is wholly black, with merely a few slight indications of the ochreous-yellow colouring: all the claws deep brown. Another, rather smaller, has the appearance of great age, with most of the plates of its carapax more or less completely united so that the form of some cannot be traced. Colour irregularly mingled black and dull buff-yellow; the plastron chiefly black and

several of the claws are yellow wholly or in part. Hab. Arakan ; Tenasserim Provinces. Specimens presented by Capt Phayre.

(6925) *Testudo elongata*, Blyth. Small Burmese land Tortoise. Carapax elongate, becoming more so and quite smooth in adults, wherein it approaches to a semi-cylindrical form ; flattish, sub-even, the three medial vertebral plates lying almost in a plane, and the free marginals slightly reverted. Caudal broader than the last vertebral. Nuchal twice or thrice as long as broad, and even with the borders of the anterior marginals. Gulars not notched, or but very slightly so. Caudals divergent from base, and transversely elongate-triangular, broader than long, forming a slight lateral notch with the ventrals. Beak laterally notched or distinctly three-pointed. Scales of the limbs rather small, contrasting much with those of the preceding species. Colour of half grown specimen orange-yellow, each plate having a large black centre, which mostly disappears with age, leaving a few more or less radiating black spots on those of the carapax, and often a black spot on only the large medial plates of the pastron. Head and limbs brown, much tinged with yellow. Length of an adult 13 in. in a straight line, by 8 in. across, or rather more towards the hinder part of the body. Height 5¼ in. Head to occiput 2¾ in. Hab. Arakan. Specimens presented by Capt. Phayre.

According to Dr. Helfer, Tortoises abound in the Tenasserim Provinces, and are much eaten by the Peguers and Karens, who train dogs to search for them.

In India proper and also in Ceylon, only one species of land Tortoise occurs viz.

(6926) *Testudo stellata*, Schweigger, a figure and interesting notice of which are given by Capt. Hutton in *J. A. S.* VI, 689, under the supposition of its being T. geometrica. The latter is a S. African species, very similar to T. stellata, but having a distinct nuchal plate, which T. stellata does not possess, and exhibiting certain other distinctions. Among some Tortoises, however, presented to the Society by Capt. Shervill from S. Africa, are two small specimens of *geometrica*, and one full grown example which can in no way be distinguished from the Indian *stellata*. The latter does not inhabit Lower Bengal, and is rarely brought alive to Calcutta. One much more commonly brought there is the T. radiata, Shaw, a larger species remarkable for its very hemispherical form, and which is said to be indigenous to Madagascar, in which case it is probably brought to India from the Mauritius. The very large specimen referred by Blyth to stellata (v. *actinodes*) in a note to p. 462 *ante*, he now thinks, after much consideration, to be distinct, and indicates as,

(6927) *Testudo Megalopus*, Blyth, *n. s.* Similar to T. stellata, but attaining a much greater size, with proportionally much larger feet and claws. The colours duller and therefore less strongly contrasting, and the lines radiating from each boss of the carapax more numerous. Fore-feet with two large claw-like scales of equal size behind the palm, and no others approaching them in size. Claws of hind-feet fully twice as large as in adult *stellata*. Length of carapax, measured in a straight line, 12 in., by 7½ in. in diameter-breadth. Hab.— ?

(6928) *Testudo*. There are several living specimens about Calcutta, of the great Seychelle Tortoise, miscalled T. Indica by Gmelin, and under which Mr. Gray unites no fewer than seven of the supposed species admitted by M. M. Dumeril and Bibron. According to Dr. Schlegel, "The Indian Tortoise [so-called], probably indigenous to Madagascar and the neighbouring isles, has been acclimated in the Gallapagos Isles, in California, and on several other points on the western coast of South America :" but we have been assured, on good authority, that numerous specimens kept in gardens in the Mauritius, have all been brought from the Seychelle Islands in the first instance, that they are still commonly brought from those islands to the Mauritius, and thence we believe the few in India have been imported. It is most assuredly not an Indian reptile, nor have we heard of its ever propagating in this country. [Mr. Blyth adds :—In the Mauritius I am informed that it is eaten. The largest I have seen is in my own possession, alive, and measures 4 ft. 4 in. in length over the curve of the carapax, or 3 ft. 5 in. in a straight line ; transversely 4 ft. 2 in. over the high arch of the carapax, or in a diameter line 2 ft. 2 in. : height, when not raised upon the legs, *i. e.* height of shell, 20½ in. ; when walking, the shell is lifted fully 6 in. from the ground, if not more : circumference of hind-foot 17½ in. A scientific friend, recently from Jamaica, assures me, that this great Seychelle species is quite distinct from the great Gallapagos Tortoise, which has bred and multiplied in Jamaica and other W. India islands. Curious, that these gigantic land Tortoises (diminutive, however, in comparison with the extinct Indian Colossicheilis) should thus be indigenous to small oceanic groups of islands, in each case remarkable for the peculiarities of both their *fauna* and *flora*. We are reminded of the great wingless birds (Dodos and Solitaires) of the Mauritius, Bourbon, and Rodrigues ; those also of N. Zealand and of Madagascar ; the Megapodius of the Nicobars, and its congeners of other islands ; the singular and quite recently extinct great Parrot of Philip Islet near Norfolk island, with its sole congener in N. Zealand ; the Owl-like nocturnal Cockatoo of N. Zealand, also close upon extirpation, &c. The majority, if not all, of these islands appearing to be remnants of what may be comparatively

termed continents, each with its peculiar centre or centres of creation. In all these supposed reliques of ancient lands, with the chief exception of Madagascar, mammalia are rare, and are chiefly or wholly *Cheiroptera*, *Rodentia*, and *Marsupialia*; the two former orders comprising the only placental mammalia of Australia; and one species of each of these placental orders being the only known indigenous mammals of N. Zealand, though a large Badger-like animal has lately been reported in the latter country, in all probability a marsupial. Madagascar is very remarkable for the extraordinary development of the quadrumanous group of Lemurs, among the higher placental mammalia; and has even a rodent Lemur in Cheiromys, as Australia has a rodent marsupial in Phascalomys. Its other placental mammals are mostly of peculiar genera, unknown even on the neighbouring continent of Africa; and no marsupial has been discovered there.]

(6929) *Testudo Horsfieldi*. From Afghanistan Mr. Gray describes a T. Horsfieldi, which he suggests may be T. Iberia, Pallas, *Faun. Casp*, t. 5. The Society's museum possesses a land Tortoise from that country, which however belongs to the genus Homopus, having but four claws to each foot. It may be thus described, viz;

(6930) *Homopus Burnesii*, Blyth. Carapax squarish, depressed, broadest posteriorly, where the free marginals are a little reverted and distinctly serrate. Anterior border straight, the nuchal plate well developed. Caudal as broad as the last vertebral, and broader than the other vertebral plates. Nucleus of each lateral or dioscoidal plate near its inner or upper border. Gular plates longer than broad, the two forming a nearly equilateral triangle. Anals oblong, divergent, forming a rather deeply notched border. Scales of forelimbs rather large, and those to the front mostly uniform in size. Claws elongate, or not worn down by attrition. Beak three-pointed. Colour yellow above, with black nuclei to the plates: those of the plastron black with yellow border. The head and limbs appear to have been yellowish. Length of carapax 6 in., by 5¾ in., measuring straight. Height 2⅞ in. Head to occiput 1⅓ in. This large specimen was procured in Afghanistan by Sir A. Burnes. A very small Homopus in spirit, also from Afghanistan, is doubtless the young, though exhibiting some remarkable differences in the shape of the upper plates. In this the nuchal is roundish, or as broad as long; and all the vertebrals are about equally broad. Colour dull yellow throughout. Presented to the museum by Terrapus. Dr. Allan Webb.

Of the numerous true Terrapins (*Emys*) of the Gangetic rivers, only three species are common in the vicinity of Calcutta; and adults of all are rarely met with. These are.—

REPTILIA OF SOUTHERN ASIA.

(6931) *Emys Thurgii* Gray, which attains to a much larger size than has hitherto been described, adults measuring 20 to 22 in. (straight) in length of carapax.

(6932) *Emys Tectum*, Gray; the adults of which measure similarly 6 in.; and E. Hamiltonii, Gray, the adults of which measure similarly 5½ in.

(6933) *Emys Tentoria*. The only other species we have yet met with from this vicinity is E. Tentoria, Gray, one young specimen only. This Mr. Gray describes from the Bombay Dukun, where procured by Col. Sykes; and Sir Alexander Burnes obtained an adult from the Indus, which is now in the Society's museum. These two specimens differ in some respects from each other, also from Mr. Gray's description, and from Buchanan Hamilton's coloured figure, the two latter again presenting certain discrepancies one from the other. The species is nearly allied to E. Tectum, Bell, but at all ages has the median keels to the first three vertebral plates much less devolped, and the whole carapax is conspicuously flatter and broader. A peculiarity of both species consists in the peculiar decanter-shaped form of the fourth vertebral plate. Comparing the adult of E. Tentoria from the Indus (length of carapax, measured straight, 6¾ in.,) with an adult of E. Tectum from the Hughly (carapax, similarly measured, 6 in.), the first vertebral plate is proportionally much broader in the former, pentagonal, narrower to the front, with a broad straight transverse base posteriorly, and the keel little developed; whereas the first vertebral plate of E. Tectum is pentagonal, broader to the front, with a rounded posterior base, and much more developed keel. In the former, the first vertebral is considerably larger and somewhat broader than the second, whereas in the latter it is sub-equal or even rather smaller than the second: in adult E. Tentoria the second vertebral plate is hexagonal but almost square, and rather broader than long, with the keel nearly obsolete; in E. Tectum, somewhat pear-shaped, truncate to the front and narrowing and curving off posteriorly, with the keel strongly marked: the third vertebral plate of adult Tentoria is quadrangular, longer by half than broad, with the keel quite obsolete on the anterior half, and flat and but little raised posteriorly; in E. tectum it is hexagonal, with the keel strongly developed and prolonged backward. A narrow black line is continued along the spinal ridge of E. tentoria; whereas the middle of the ridge is broadly white in E. tectum, bordered by a black line on either side. The plastron of E. tentoria is blackish-brown, with a pale border to each plate; in E. tectum pale with two or three distinct blackish patches on each plate. Comparing the young of the two species, the first vertebral plate forms a much broader

pentagon in E. tentoria, being equal in breadth to the second; in young E. tectum the first vertebral plate is considerably narrower than the second: the second vertebral plate in young tentoria forms a heptagon with the base posteriorly; in young tectum a pentagon with rounded apex and anterior base: the third in young tentoria is subquadrilateral, somewhat longer than broad with the keel a little produced posteriorly; in young tectum a pentagon with its base to the front, and the keel much broader and more prominent. Yet, notwithstanding these great differences of detail, and also of the colouring of the head, neck and limbs, the two species are very liable to be confounded on a superficial glance.

(6934) *Emys Trijuga*, According to M.M. Dumeril and Bibron, Schweigger, was obtained by M. Duvaucel from the "salt-water lake" lying east of Calcutta; but of the numbers of Terrapins which we have seen from that locality, we have sought in vain for this species, which belongs to the peninsula of India, and is the only one which has been there observed, with the exception of Col. Sykes's specimen of E. Tentoria.

(6935) *Emys Dhongoka*. [Since the above was printed, we have obtained another Emys from the vicinity of Chaibasa, which appears to be the young of E. dhongoka; and Mr. Jerdon assures me that a large species abounds in the Nerbudda, 2 feet and upwards, which is probably the same: it is not referred to in Mr. Jerdon's paper, p. 463 *ante*.]

(6936) *Emys Sebæ*. In Ceyon E. Dhongoka is replaced by the very distinct E. sebæ, Gray.

(6937) *Emys Dhongoka*. On the Arakan coast, adults of Emys Dhongoka, Gray, approaching to 2 feet in length of carapax, would appear to be very common; but the only young specimen which we have seen of this species was sent down alive from Assam by Major Jenkins, and is now mounted in Calcutta museum. The adults have much the appearance of Tetraonyx Lessonii, D. and B., but are readily distinguished by having five instead of four claws to the fore-feet.

(6938) *Tetraonyx Lessonii* abounds at the mouth of the Hughly, and great numbers are brought to Calcutta, where they are eaten by particular castes of Hindus and are even kept for sale in tanks. Though the water-Tortoises generally are much used as food, the species chiefly consumed, or at least which are brought in greatest quantity for that purpose, are Tetraonyx Lessonii and Emyda punctata. The latter appears to be the most generally diffused species of Tortoise throughout the whole of India and Ceylon, and is very abundant in Lower Bengal, burrowing deep into the beds of tanks when the water dries up. A large one which escaped into the Bengal Asiatic Society's compound was found several months afterwards in a healthy state, buried among the roots of some guinea grass.

A small and evidently young Emys from Arakan or Tenasserim would seem to be

(6939) *Emys ocellata*, Dumeril and Bibron. The colouring agrees with the description; the details of structure less completely. Length of carapax 6 in. (measured straight). It is affined to *E. Thurgii*; and, as compared with a specimen of *E. Thurgii* of the same size, it is at once distinguished by having the whole under surface of the shell spotless yellowish-white, and each lateral or discoidal plate of the carapax is marked in the centre with a large round reddish-brown spot, surrounded by a pale areola; an interrupted black line along the spinal ridge, which is raised into keels on the first four vertebral plates. These are of equal breadth, whereas in *E. Thurgii* the first is much narrower than the others. Nuchal plate twice as long as broad and throughout equal; whereas in *E. Thurgii* it is triangular with posterior base. Hindmost vertebral plate much narrower than in *E. Thurgii*; and the posterior marginals and especially the caudals are much smaller than in that species. Colour of the upper parts greenish-olive-brown, with the ocelli before mentioned, which probably become obscured with age. Head brown above, with yellow superciliary line meeting its opposite over the nostrils, and another proceeding backward from the eye. Limbs and under parts apparently yellowish without markings. There is a species of Chamelon in the Society's old collection, the origin of which is unknown, but it would appear to be undescribed. It would seem to be most nearly affined to C. cucullatus, Gray, and has the occipital flaps of both that species and Ch. delepis, Leach.

(6940) *Chameleo verrucosus*, Blyth. Body minutely tuberculated, with larger tubercles regularly intrespersed throughout. The latter are smaller and contrast less strongly on the limbs and tail, and are more thickly set upon the limbs. Ridges of the back and throat serrated, the tubercles becoming smaller towards and upon the tail. Beneath, the tail is smooth, though tending to exhibit a slight serrature towards its base. Superciliary ridges not uniting together, either before or behind; and a small medial occipital ridge continued to the base of the two lateral flaps or lappets of skin. Colour of the specimen blanched; but there is a strongly marked black streak proceeding backward from the axilla, and surmounted by a white streak, the two occupying the space which may be concealed behind the humerus. Length 11¼ in., of which the tail is 6 in. Hab. unknown.

(6941) *Leiurus Berdmorei*, Blyth (*Geckoidæ*.) Agrees with Mr. Gray's definition of *Leiurus*, except that there is no appearance of the toes being webbed at base. Colour grey, with 4 longitudinal blackish streaks along the back and

sides, 3 or 4 interrupted crossbands of the same on the upper surface of the tail, a medial black streak on the nape, and others successively diverging on each side of it, and a black streak from before the eye continued to the shoulder. Some mottling also on the limbs. Hab. Mergui, where procured by Capt. Berdmore.

(6942) *Stellio.* The genus *Stellio* is new to the Indian fauna. A species from Upper Hindustan cannot be safely separated from the Arabian *St. Cyanogaster*, Rüppell, unless upon comparison of specimens. The tail, however, appears to be longer; and there is a slight gular *fanon*. Specimens vary much in colour. An adult from Mirzapore, presented by the late Major Wroughton, measures 12½ in. long, of which the tail is 8 in. Throat blue, spotted over with yellowish-white, deepening to purple on the *fanon* which is less spotted. The rest of the lower parts are yellowish-white, marbled on the transverse fold of the neck and immediately behind it with blackish, and spotted with the same on the breast and belly, the spots becoming less numerous on the latter. Upper parts dark olive-green the back and sides speckled over with whitish. Two smaller specimens were presented to the Society by L C Stewart, Esq. now of H. M. 61st Regt. from Wuzeerabad. Length of one 8¾ in., of which the tail measures 5½ in. In these the under parts are yellowish-white, suffused or marbled with bluish or pale dusky on the throat, and slightly spotted with the same on the breast. Upper parts paler olive-green than in the large specimen; the back and sides speckled with yellowish-white in one, as in the adult example, with traces of dusky marbling on the back; in the other, the back is much more marbled and blotched with dusky, and has only a few largish dull white spots on the back and sides, while the limbs and tail are banded, and there are three dark transverse lines over each eye. If new, it will be the St. indicus, Blyth.

(6943) Genus *Calotes*, Kaup. We have now nine well marked species of this genus in the calcutta museum. The first three are distinguished by a pit or fold before the shoulder, which is lined with minute scales.

(6944) *Calotes. emma*, Gray (vide "Proceedings of the Asiatic Society" for May, 1853, p. 413.) Inhabits Mergui, and probably other parts of Burma, ranging northward perhaps to the Khasya hills; but extremely doubtful as an inhabitant of Afghanistan. We have elsewhere expressed our suspicion (*loc. cit.*) that collections made by the late Dr. Griffith in Afghanistan and in the Khasya hills had become mixed and confounded, and hence that Mr. Gray had been led to assign his Calotes emma, C. maria, C. minor, and Salea Horsfieldi to Afghanistan, and two of the four to the Khasyas also; countries so extremely different, that it is most improbable that the same species would be found to inhabit both of them.

(6945) *Calotes mystaceus*, Dumeril and Bibron. (Described *J. A. S.* XXI, 754). Inhabits Burma, and also the mountainous parts of Ceylon. Hind-toe reaching to the ear.

(6946) *Calotes Rouxi* (?), Dumeril and Bibron. Three adult specimens and another half-grown forwarded by Dr. Kelaart from Newera Elia, in Ceylon, accord fully with the description as regards structure; but the colouring is remarkable, and different again from that of Mr. Jerdon's supposed C. Rouxi of S. India. Pit before the shoulder more developed than in C. Mystaceus, and partially black. Hind-toe reaching to the eye. A row of 3 or 4 raised spines above the tympanum; and nuchal crest moderate and gradually diminishing to the tail. The latter is tumid at base, and soon attenuates rather suddenly, the tumid portion exhibiting a median ridge of very broad keeled scales. Caudal scales towards the base of tail much larger than those of the body. Throat scales very broad and flat, with a median row of narrow compressed scales imparting the appearance of a small *fanon* or dewlap. A half grown specimen (in spirit) is blue, with the tail reddish-brown to near its base, and marked with an irregular double series of *ocelli* which are white, having a black border. A few similar *ocelli* are seen bordering the low spinal crest. There is a black mark between the eye and the ear, and another below the eye; and a tinge of ruddy on the throat, about the tympanum, and on the occipital and tympanic spines. Adults (in spirit) have the body and limbs blue, the tumid base of tail green, and the rest of the tail dull red-brown, with *ocelli* less bright than in the young. Borders of lips black, continued as a broad black band (more or less variegated with ruddy-white) to the shoulder-pit. Throat whitish tinged with ruddy and strongly contrasting, as also a white band from the tympanum continued over and passing the shoulder-pit. In some, the shoulder pit is also posteriorly margined with a white mark; and raising the fore-leg, two or three additional white stripes are seen, oblique and successively more inclining to the horizontal. The limbs are also banded with white; but these markings are often indistinct or obsolete. Tumid base of tail bright orange underneath in some specimens. C. Rouxi is described from Burma; but as we possess the preceding species both from Burmah and the mountains of Ceylon, it is the less improbable that the present may have the same habitat.

(6947) *Calotes Gigas*, Blyth, (Supposed C. ophiomachus, *J. A. S.* XI, 870). Resemble C. versicolor, except in being much larger, having no tract of gular *fanon*, and a *double* nuchal crest of spine-like scales, ½ in. long in the specimen under examination. Dorsal crest also propor-

tionally more developed than in C. versicolor, and terminating abruptly over base of tail. Length of head and body 5¾ in. Of tail—? Of hind-limb 3¾ in. Colour apparently uniform without markings, but the specimen is much blanched. Hab.—?.

(6948) *Calotes versicolor*, Daudin. The most common and generally diffused species, inhabiting all India and Ceylon, from the base of the Himalaya southward, and (according to Mr. Gray) also China and Afghanistan (vide, however, remarks on C. emma). It is the only species we have in Lower Bengal, where it is excessively abundant particularly in gardens. Sir A. Burnes sent a specimen from Sindh; and we have also one from Rangoon. In the last, however, the scales are somewhat smaller than in Indian specimens, and the two detached spines on the tympanic ridge are remarkably minute; but there is no other difference. Ceylon specimens, on the other hand, appear commonly to attain a greater size, with somewhat larger scales, the nuchal and dorsal crests and also the gular *fanon* being rather more developed (and they are then the supposed C Rouxi *apud* Blyth of *J. A. S.* XXI, 354); but smaller and younger specimens from Ceylon are quite undistinguishable from Bengal examples; and it may even be that the latter sometimes attain the size and general development of the Ceylon reptile. [Some *living* examples sent from Galle by Dr. Kelaart are quite undistinguishable from living Bengal specimens.] In S. India, again, the changes of colouring (as described by Mr. Jerdon) differ from those of C. versicolor of Bengal, and are perhaps the same as in the Ceylon animal. Here the colours are changeable, but no yellow is ever seen; and in the months of May and June, the males chiefly are often observed with the head and anterior third of the body, inclusive also of the fore-limbs, tolerably bright red, a large black patch before the shoulder, and all the rest plain greenish-brown. They are often altogether of the latter hue without markings; or the markings come out more or less strongly. The reptile is then commonly brown, lighter or darker, with a series of transverse dusky bands, broken on either side by a longitudinal whitish band which is evanescent appearing and disappearing and sometimes shewing very conspicuously. A dusky streak through the eye, and three others radiating below and two above it. Three or four oblique streaks on each side of the throat; and others on the limbs. Females are smaller and darker, generally of the hue of the ground on which they lie.

(6949) *Calotes viridis*, Gray. Nuchal crest extremely slight; and no decided spines above the tympanum, but three raised angular scales placed not on a ridge, but disposed triangularly and separated apart. In some specimens, probably the females, the latter are scarcely noticeable.

There is also a row of five flattened scales from below the eye to above the tympanum. Two longest hind-toes of subequal length and reaching only to the ear. Body scales acutely pointed, especially those of the lower parts. Colours green or brown, mottled with whitish and with dark brown; lips black. From S. India.

(6950) *Calotes ophiomachus*, (Merrem). Tympanic ridge with several short and two longer spines. Longest hind-toe reaching to front of eye. Tail extremely long, its terminal three-fourths commonly whitish. General colour green, paler below; with some irregular white transverse bands on the body in adults. Stripe through the eye red; and nuchal crest and throat the same in the breeding livery of the males. One Ceylon example (in spirit) is remarkable for having a longitudinal white lateral band, continued from the shoulder to the tail upon which it becomes broken and lost. Identical from S. India, Ceylon, and the Nicobar Islands.

(6951) *Calotes platyceps*, Blyth. *J. A. S.* XXI 354. Hab. Khasia hills.

(6952) *Calotes tricarinatus* Blyth. Founded ona young specimen of a well marked species, affined by the flat form of the head to the last, but particularly distinguished by having three low crests or keels along the nape and shoulders. An oblique row of six large triangular scales over each tympanum, but no spines (perhaps on account of youth). Longest hind-toe reaching to tip of muzzle. Colour (in spirit) blue above, white beneath. From near Darjiling, where procured by Capt. Sherwill.

(6953) *Aspris*, Blyth, *n. g.* (*Scincidæ*). Affined to Tropidophorus, *Dumeril* and *Bibron*, but differs much in the arrangement of shields upon the head, and the face anterior to the eyes is compressed and narrow, with subacute muzzle. Tongue very slightly notched. Teeth extremely minute. Frontal shield elongate-pentangular, attenuating much posteriorly: front-parietals triangular and contiguous; parietals large, subovate; interparietal smaller, elongate and obtusely pentangular; superciliaries five in number, broad, the two series separated apart by the narrow hinder part of the elongated frontal shield. Scales of the back and upper part of tail rhombic, strongly carinate, the keels running in parallel ridges; of the belly roundish, smooth. Præ-anal scales 2, large, triangular. Toes 5—5, simple, slender.

(6954) *Aspris Berdmorei*, Blyth, *n. s.* Colour dusky-brown or blackish, the throat and belly ruddy-white, with some cross-bands of the same upon the neck and body, broader and more distinct on the former, and white specks on the lips, chin, and on the under and laterial surface of the tail. Eight distinct rows of keeled scales along the back. Length of specimen 4⅝ in., of which the tail is 2⅜ in., and head $\frac{9}{16}$ in., fore-

limbs $\frac{9}{16}$ in.; hind-limbs $\frac{1}{16}$ in. Hab. Mergui, where procured by Capt. Berdmore.

(6955) *Mocoa formosa*, Blyth, *n. s.* Length of one 7 in., of which the tail measures half. Scales hexagonal, in six dorsal series. Præ-anal scales similar to the abdominal. Form robust. Frontal shield elongate-pentagonal, broadest to the front, and rounded posteriorly. Inter-nasal and fronti-nasals lozenge-shaped, or somewhat fan-shaped, broader than long. Fronti-parietals distinct, but unsymmetrically divided. Colour olive-green, with black lateral and pale superlateral bands as usual, the former much speckled with greenish-white, and the latter shewing a series of black spots. Between the pale superlateral streaks are five narrow black lines along the nape and body, variegated with angular greenish-white spots. A few such spots appear also on the upper surface of the tail, caused by a scale variegated with black and greenish-white here and there placed. Limbs minutely pencilled with black, and spots or streaks of the same upon the head. Under-parts greenish-plumbeous throughout. This large specimen was procured at Mirzapore by the late Major Wroughton; and others, from Wuzeerabad, presented by L. C. Stewart, Esq. now of H. M 61st Regt., are smaller and less marked with black, which does not form continuous lines along the back, but variegated scales (black, with pale medial portion,) are throughout scattered, and there are some black markings on the head..

(6956) *Mocoa Sikimmensis*, Blyth, *n. s.* A small species, about 4 in. long, the tail varying in length in different individuals. In one the head and body measure $1\frac{5}{8}$ in., the tail $2\frac{3}{8}$ in.; in another the head and body measure $1\frac{3}{4}$ in., the tail but 2 in. This difference is probably sexual, the former proportions denoting the male, and the latter the female. [The same variation occurs in the species of Riopa, Gray.] Closely affined to the preceding species, but much smaller, flatter, and more lustrous, with proportionally much more slender toes. Colour of the upper parts nacreous olive-green, with three irregular black lines or rows of specks along the back, not always very conspicuous. A broad black lateral band, becoming obsolete along the sides of the tail, is margined with a glistening pale greenish stripe above, and variegated with spots of the same along its lower half and on the outside of the limbs. Under-parts greenish-white, except the tail and below the limbs where the colour is rufous-white. Some have a few dark spots on the throat. Inhabits Sikim, where procured by Capt. W. S. Sherwill.

(6957) *Plestiodon Quadrilineatum*, Blyth, *n. s.* Proportions of Tiliqua; the head small, but its plates almost exactly as in Pl. Laticeps of N. America. Colour blackish above, pearly white below; two dorsal greenish-white streaks, commencing at the nostrils and gradually disappearing at about the middle of the tail; these streaks being exterior of the two alternating series of medial and hexagonal dorsal scales; also a lateral pale streak from fore to hind limb, which is more or less indicated on the neck and base of tail, close upon the whitish hue of the under-parts. Length $7\frac{1}{2}$ in., of which the tail mersures $4\frac{3}{4}$ in.; of hind-limb $\frac{15}{16}$ in. China (Hong Kong ?). J. C. Bowring, Esq.

(6958) *Euprepes macularius*, Blyth, *n. s.* Affined to Eu. cyanogaster. (Lesson, v. *Eu seichellensis*, D. & B.) Like Tiliqua rufescens, (Shaw), but the scales of the upper-parts 5-7 carinate, and colour bronzed olive-green above, pale below; the hinder half of back and base of tail above marked with irregular reddish-brown spots, and a broad reddish-brown lateral streak continued from the ear to the middle of the tail, marked throughout with white, which tends to form continuous lines posteriorly. Terminal half of tail whitish. Arms and hind-limbs speckled with white posteriorly. Length of specimen $5\frac{1}{4}$ in., of which the tail measures $3\frac{1}{2}$ in. Inhabits Rungpore ?

(6959) *Lissonota*, Blyth, *n. g.* Form of Euprepes, but more slender, covered with very smooth minute uncarinated scales. Head short, flat, subtriangular as viewed from above, broader than high, with obtusely pointed muzzle. Tympanum distinct, roundish. Lower eyelid scaly. Palatal incision slight, placed far back. Tongue scarcely notched. Teeth very minute. Frontal shield pentagonal, subtriangular, broad to the front, and elongated to an obtuse point posteriorly; the supra-orbitals nearly meeting across. Inter-nasal hexangular, somewhat fan-shaped. Fronti-nasals small. Fronti-parietals two, contiguous. Inter-parietal squarish or diamond-shaped. Limbs well developed. Toes 5-5, the palms and the heels (or exterior portion of soles) granular. Infra-caudal scales larger than those of the body; and two large triangular præ-anal scales.

(6960) *L. maculata*, [This species would seem affined to *Plestiodon sinensis*, Gray.] Blyth, *n. s.* Colour (in spirit) greyish olive-green, with a double row of irregular dark spots along the nape and back, and a median line of the same along the tail. On each side a dark band is continued throughout, commencing at the nostrils; and beneath this is a narrow pale streak, then a narrow dark one, and finally a few dark spots on the sides of the throat and belly. Upper surface of the limbs variegated throughout. Lower-parts albescent-greenish. Length of specimen,—head and body $1\frac{1}{8}$ in., and tail probably about the same, but the tip is wanting. Fore-limbs $\frac{5}{8}$ in.; hind limbs $\frac{13}{16}$ in.: distance apart of fore and hind limbs 1 in. From Assam, Col. Jenkins.

(6961) *Ophiops Jerdoni*, Blyth, *n. s.* A typical species, dark brown above, black-spotted, with two obscure broad dorsal streaks; below white throughout. Length of head and body $1\frac{1}{2}$

in. ; of tail 2¼ in. ; of hind-limb, to extremity of longest toe, ½ in. Femoral pores 7 or 8. Shields of head plaited longitudinally. "Procured at Mhow, in pasture land." T. C. Jerdon, Esq. [Since Mr. Jerdon's paper on the reptiles of S. Indian was ready for publication. With reference to that paper, p. 468 *ante*, he desires me to state that "the only specimen of Homonota fasciata was taken from the mouth of a snake, in grassy land, near Jaulnah."]

(6962) *Sphenocephalus*, Blyth, *n. s.* A *Sepsoid* form affined to Sphenops, Wagler, but with more slender and elongated shape, and the limbs placed more distantly apart; the anterior minute and fitting into a groove, the posterior as large as in Sphenops, and each having but three toes, of which the innermost and next are subequal and the outer much shorter. [It is still more nearly affined to the Australian form Ronia of Gray, figured in the Appendix to Grey's Journal; but this has still more rudimentary limbs, the anterior merely indicated externally, and the posterior shewing but two digits.] Form slender, ⅔ cylindrical, quite flat and laterally angulated beneath as far as the vent: the body and tail covered with small, smooth, lustrous, hexagonal scales, with a median row of broader scales along the under surface of the tail. Head much as in Sphenops, but the muzzle more pointed; the upper lip covering the mouth. Tongue broad, triangular, its cleft scarcely perceptible; the incision of the palate small. Teeth very minute. Eyes minute, with semi-transparent lower lid. No external trace of ear. Nostrils terminal, placed in the anterior margin of the nasals, contiguous to the front of each inter-nasal and the rostral; rostral equilaterally triangular: supra-nasal broad, heptangular, with apex to the front, fronti-nasals sub triangular, a little elongated; frontal obtusely subtriangular; parietal inequilaterally pentangular, with obtuse posterior base, single and as large as the frontal. A large subquadrilateral plate under the eye, and three small transversely narrow plates in front of it, and posterior to the nasal plate. A large diamond plate on centre of chin, emarginated anteriorly to admit a small roundish plate which is bordered by the anterior laterals. Tail shorter than the body, and sub-cylindrical, flattened below.

(6963) *Sphenocephalus tridactylus*, Blyth, *n. s.* Very pale brown, a little deeper on the upper-parts. The largest of six specimens, measures 6 in. in total length, of which the tail is 2 in, and distance apart of the fore and hind limbs ½ in. Length of fore-limb ⅛ in.; of hind $\frac{9}{16}$ in. From Afghanistan. Presented by Dr. Allan Webb. The habit of this curious reptile is indicated by its structure. It is evidently a burrower, probably into loose sandy soil, where it would work its way with its wedge-like muzzle, deriving considerable *appuis* from its hind-limbs; the minute forelegs remaining generally close within the grooves into which they fit; the head meanwhile being raised, and the long body arched,—an attitude which most of the specimens assumed when immersed in spirit.

The following is a remarkable limbless lizard from Rangoon, obtained by purchase.

(6964) *Ophiseps*, Blyth, *n. g.* Form anguine, of nearly uniform bulk throughout, tapering suddenly at the extremity of the tail; no exterior trace of limbs; and the vent placed in the middle of the entire length; the body above, and tail above and below, covered with parallel ranges of quadrilateral keeled scales, the throat and belly with hexagonal smooth scales, and the tapering extremity of the tail with imbricated and rounded scales. A groove on each side from shoulder to vent. Tongue obtusely forked: no palatal teeth; but a single row of small maxillary teeth, the triangular incision of the palate large. Eyes rather small, lacertine; the lids scaly. Tympanum small. Nostrils small, lateral, head conical, somewhat compressed in front, the cleft of the mouth extending to beyond the eye. Rostral plate small, broad, triangular; it and the nasals and anterior labials surmounted by numerous small plates and larger representatives respectively of a posterior nasal and united fronti-nasals. Frontal shield large, heptagonal with posterior base; and the parietal inequilaterally pentangular, with anterior base. Fronti-parietals quadrangular. The streaks of the chin are sub quadrangular and placed obliquely. Along the median ridge of the back the parallel ranges of scales alternate, but not upon the tail.

(6965) *Ophiseps Tessellatus*, Blyth, *n. s.* Length of specimen 12½ in., of which the tail measures 6½ in. Colour pale dingy buff-yellow, paler below, with numerous plumbeous spots on the anterior half of the body above, composed of scales of that colour, some detached, others placed contiguously to form transverse bands more or less imperfect; all the scales being highly lustrous. There are 14 parallel ranges of them above, from lateral groove to groove, and 8 such ranges below. From Rangoon.—*Blyth.*

REPTILIA OF TENASSERIM.—On these, Mr. Mason observes as follows:—

(6966) *Testudo radiata*, Small land tortoise. A small land tortoise is very common, and Dr. Gould, to whom I sent a specimen, said it was the above.—*Mason.*

(9967) *Testudo.* Large land tortoise. There is a large species, not uncommon in the interior.—*Mason.*

(6968) *Testudo geometrica.* Arracan land tortoise. A land tortoise in Arracan discovered by Capt. Phayre is the above.—*Mason.*

(6969) *Emys.* Marsh tortoise. A marsh tortoise, according to Dr. Cantor's classification, but according to Swainson and others, a river tortoise, is very common in Tenasserim streams

above tide-waters, where it deposits its eggs in the sand; and is sometimes found within the influence of the tides.—*Mason.*

(6970) *Cistudo amboinensis*, Daudin. Box terrapin.

Syn. Testudo amboinensis, Daudin.
Emys „ Schweigger.
Tortue a' boite d' Amboine, Bosc.
Terrapene amboinensis, Merrem.
Kinosternon amboinense, Bell.
Terrapene couro Fitzinger.
Emis couro, Wagler.
Terrapene bicolor, Bell.

This is a small marsh, or river tortoise, very abundant in the small mountain streams.—*Mason.*

(6971) *Emys dhongoka.* Arracan marsh tortoise. This river or marsh tortoise, Capt. Phayre found in Arracan. —*Mason.*

(6972) *Gymnopus*? Soft tortoise. A river, or soft tortoise, is not uncommon, but I have not examined it.—*Mason.*

(6973) *Chelonia virgata*, Cuvier. Green turtle.

Syn. Chelonia midas, Gray.
„ fasciata.

The sea turtle common on the Tenasserim coast is identical in species with the turtle found on the coasts of America, and in the Red Sea. This turtle burrows, and deposits its eggs in the sands near the sea-shore.—*Mason.*

(6974) *Chelonia imbricata*, Linne. Tortoise-shell turtle.

Syn. La tortue caret, Dutertre.
Scaled tortoise, Grew.
Testudo marina americana, Seba.
Hawksbill turtle, Brown, Catesby.
Testudo caretta, Knorr.
La tuilee, Daubenton.
Caretta imbricata, Merrem, apud Gray.
Chelonia multiscutala, Kuhl?
Cheloniee faux caret, Lesson.
Chelonia caretta, Temminck, and Schlegel.

Mergui is famous for its tortoise shell, but the specimens that have fallen beneath my observation have been, if I am not mistaken, the shell of the common green turtle. Still, it is probably found on Tenasserim coasts, for it is known to exist in the Malayan seas and the Indian ocean. —*Mason.*

(6975) *Crocodile.* Two species of crocodile inhabit Tenasserim rivers, and sea-shores, both of which are usually denominated alligators; but alligators are peculiar to America, and a glance at the scaly ridge on the back of the hind legs of the Tenasserim reptiles is sufficient to distinguish them from the alligators, which have the hind legs rounded.—*Mason.* Dean French, in his "Study of Words," *page* 125, says. "when the alligator, this ugly crocodile of the New World, was first seen by the Spanish discoverers, they called it, with a true insight into its species, 'el lagarto' or the lizard, as being the largest of that lizard species to which it belonged.

(6976) *Crocodilus vulgaris*, Cuvier. Common crocodile.

Syn Crocodilus palustris, Lesson.

The common crocodile of the Nile, the leviathan of the book of Job, is one of the species common in Tenasserim waters, and the other species is very slightly distinguished from it. Crocodiles are numerous in all its tide-water streams. During a two hours' pull up a small river, I once counted fourteen sunning themselves on the mud-banks. They often carry off the natives, and a single animal, emboldened by his successes, will usurp dominion over a particular portion of a river, where he becomes the terror of every boat's crew that passes. The steersman occupies the most dangerous position; for the crocodile's mode of attack is to glide up silently to the bow or stern of a boat, then turn suddenly, when with one stroke of his powerful tail, close to the top of the boat, he sweeps into the water whoever is within its reach, and the stunned victim becomes an easy prey. A Karen chief with whom I was acquainted, perished in this way two or three years ago, at a point in the river Gaing, which had previously been known as the desmesne of one of these river monarchs. Persons sleeping on their boats moored to the shore, have sometimes awaked in the jaws of these monsters; and one carried off a Burman a few years ago, from the back of a buffalo that he was riding across a small stream, under the very shadow of the walls of Tavoy.—*Mason.*

(6977) *Crocodilus porosus*, Schneider Seychelle crocodile.

Syn. Crocodilus biporcatus, Cuvier.

One species of crocodile that I examined had "the upper jaw surmounted by two rugged ridges, each commencing from the angle of the eye" This, then, is the species that tenants the Seychelle Islands.—*Mason.*

(6978) *Gecko.* The geckos, or house-lizards, are very numerous in the Provinces, and embrace three or four different species.—*Mason.*

(6979) *Platydactylus gecko*, Linne. Flat-toed gecko.

Syn. Salamandra indica, Bontius.
Gecko ceilonicus, Seba.
Lacerta cauda tereti mediocri, Linnemus. Adolph.
Lacerta gecko, Lin-linn.
Gecko teres, Lam[illegible] of Trenti.
Gecko verticillatus, Jen[illegible]orr.
Salamandre ou geck[illegible], Schneider.
Stellio gecko, Schneider.
Common gecko, Shaw.
Gecko guttatus, Daudin, apud Gray.
Lacerta guttata, Hermann.

Gecko verus, Merrem.
Gecko annulatus, Kuhl.
Gecko a gouttelettes, Cuvier.
Platydactylus guttatus, Cuv. apud Guerin.

The large gecko, which the Burmese call *touktay*, and the Malays *toke*, in imitation of the sound it makes, is very abundant. It disputes the possession of every cranny with the rats, and sometimes I think, devours their young. It has been seen making its repast on the small gecko. The natives think it noxious, and always avoid the reptile. According to Dr. Cantor, it is the Indian salamander of old writers; and new comers usually bottle up a few individuals to send to their friends as specimens of the rare, and unknown productions of the East, not aware that it was well described, and figured by the Catholic missionaries in Siam during the reign of Louis XIV.—*Mason.*

(6980) *Hemidactylus coctæi.* Common gecko. The small gecko, so abundant in Tenasserim houses, differs generically from Platydactylus Gecko, in having the "basal joint of four or five of the toes in each foot forming an oval disk." It is identical with the gecko seen in the houses in Calcutta. The spider of the English bible, Proverbs 30: 28, was undoubtedly a small gecko represented by this species, and the word was so rendered in the Syriac version made in the second century, and in the Vulgate Latin made in the fourth century. Jerome translated: "Stellio manibus nititur, Et moratur in ædibus regis," into.

"The gecko taketh hold with her hands
And dwelleth in king's palaces."

Robinson says: "The opinion of the celebrated Bochart, that the newt, a species of small lizard, is meant, seems in every respect entitled to the preference [i. e. to that of spider]. This reptile answers to the description which the royal preacher gives of her form and habits, and is, according to the testimony of ancient and modern writers, found to take up its abode in the dwelling houses of the east." There is an approximation to the truth in these remarks, yet they contain several errors. Passing over the fact that newts are not proper lizards, though supposed so to be in the days of Bochart, no newts are known to take up their abodes in dwelling houses in the east. It is the gecko that takes hold with her flat fingers, and odious as are her looks, dwells even in the palaces of kings. The word rendered "ferret" in our version, is supposed to be a different name for this same animal, and on good grounds too, for in the Samaritan Pentateuch the Hebrew word is the same in both passages.—*Mason.*

(6981) *Hemidactylus frenatus*, Schlegel. Small thumbed gecko.

Syn. Hemidactylus lateralis, Gray.
" quinquelineatus,

This species not usually distinguished from the preceding, with small thumbs without nails, is also common here as well as in Bengal.—*Mason.*

(6982) *Jungle gecko.* I have noticed a distinct species in the jungles, near Karen habitations, but never saw it in dwelling houses.—*Mason.*

(6983) *Ptychozoon homalocephalum*, Creveld, Wagler. Web-footed gecko.

Syn. Lacerta homalocephala. Creveld, Wagler.
Gecko homalocephalus Tilesius.
Pteropleura Horsfieldii Gray.
Platydactylus homalocephalus, Cuv.
Ptychozoon homalocephala, Kuhl.

Dr. Cantor describes a gecko from the island of Ramree, with the "toes webbed to the last compressed joint."—*Mason.*

MONITORS. The monitors or varans, commonly, but erroneously called guanas by Europeans, are represented by several species, both terrestrial and aquatic.—*Mason.*

(6984) *Hydrosaurus?* Swain. Monitor crocodile.

Syn. Monitor? Cuvier.

More than one hundred miles above tide-waters in the valley of the Tenasserim, the streams are inhabited by a large saurian, which the natives call a crocodile, of a different species from those that are found in tide-waters. The Burmese denominate it "the monitor-crocodile," and the Karens call it by the same name they do the crocodile, but it is probably a large species of varanus.—*Mason.*

(6985) *Hydrosaurus, ?* Swain. monitor.

Syn. Varanus.
Monitor, Cuvier.

A large water varan or monitor, inhabits the head-waters of the Tenasserim river. I have seen individuals five or six feet long dash into the stream from the river's bank, and lash the waters with their powerful tails in great glee, their active movements contrasting strongly with the sluggish motions of the crocodiles.—*Mason.*

(6986) *Varanus bengalensis.* Bengal Varan. One of the smallest aquatic varans, or monitors, of Tenasserim, about two feet long, I identified with a species found in the Museum of the Asiatic Society in Calcutta, which was, if I recollect right, the Bengal varan. It is the most abundant species in the Provinces, and may be often seen in the interior along the borders of streams, watching for its prey on the overhanging branches of trees. The Karens, who are extravagantly fond of their flesh, steal up the trees with a noose at the end of a bamboo, and often noose them while leaping for the water, or catch them on the boat which is brought under the tree. The head of this species, the natives say, is venomous, and they discard it altogether; but the flesh of the other parts, which smells most odiously, is deemed by the Karens much preferable to fowls. The Ka-

rens at Tavoy say there is a variety with a red head.—*Mason.*

(6987) *Varanus.* Terrestrial varan. A monitor or varan, of a yellowish colour, the Karens call the yellow varan. The specimens I have seen are a little larger than the preceding, and it differs from it in being a terrestrial, and not an aquatic species.—*Mason.*

(6688) *Varanus.* Black varan. According to the description of the natives, there is a distinct species of varan in the interior, which the Burmese call the black varan, but I have never seen it.—*Mason.*

(6989) *Varanus.* Maulmain varan. There is a terrestiral varan at Maulmain, which the natives describe as distinct from the preceding.—*Mason.*

(6990) *Varanus bicinctatus.* Large Arracan varan. A large varan is found in Arracan, which may or may not be one of these species.—*Mason.*

IGUANA TRIBE.

Of the family of the guanas, the principal members in the Tenasserim Provinces are called by Europeans, chamelions.—*Mason.*

(6991) *Calotes versicolor.* Blood-Suckers. This is the tree-lizard with a gular pouch, that possesses the power in a slight degree of changing its colours, and has been regarded as a chamelion. These lizards appear in very different costumes at different seasons, which has probably assisted them not a little to the name. Many of them are seen at the beginning of the rains, of a beautful azure of various degrees of intensity, according to the excitement of the reptile; but at the commencement of the dry season they are of an uniform ash colour. The karens say there are two species. This was the one I sent Mr. Blyth.—*Mason.*

(6992) *Calotes mystaceus.* Large Blood-Sucker. Mr. Blyth suggested that we probably had a large species, but I have never identified it.—*Mason.*

(6993) *Dilophyrus grandis.* Dilophyer. This is a reptile figured, and described by Dr. Cantor, said to be found at Rangoon. It resembles the blood-sucker, but has a large crest on the head and back, and differs in the colouring.—*Mason.*

(6994) *Dracunculus maculatus.* Flying lizard.

Syn. Draco Maculatus.

A species of flying lizard inhabits the Provinces, but it is rarely seen.—*Mason.*

(6995) *Draco lineatus.* Arracan flying lizard.

Syn. Dracunculus Lineatus.
Leiolepis guttatus.
„ Revesii. Gray.
Uromastix Revesii. „

The flying lizard of Arracan is a nearly related, but distinct species. It has been referred to two different genera, and there may possibly be two distinct species.—*Mason.*

(6996) *Lacerta, Linn. Sand lizard.* On sandy plains, and other arid situations a sand-lizard may be often seen, which, on being approached takes refuge in its burrow in the earth. Their cavities are not deep, and the Karens, who regard them as a delicacy, frequently dislodge them. It is a beautiful reptile, the body about six inches along, and the tail twice that length, remarkable for its powers of flight. It is of a grey colour, with shades of blue and green. It has a longitudinal band on each side from the head to the tail, of a greenish colour, sometimes inclining to blue. A row of black spots with a greenish centre down the upper parts and a few similar ones each side the marks of the back, between that and the lines on the sides The tail has four rows of similar points, and the sides of the body and legs are marked in a like manner, but the dots are larger. There are two long sharp teeth at the front of each jaw. It has five claws on each foot, and one on each hind foot is double the length of the others. There is no collar of broad scales round the neck. No shields in the head.—*Mason.*

(6997) *Euprepus rufescens.* Shaw. *Scink.*

Syn. Lacerta maritima maxima, Seba.
Lacerta rufescens, Shaw.
Scincus rufescens, Merrem.
Scincus multifasciatus, Kuhl.
Mabouya multifasciata, Fitzinger.
Euprepis multifasciatus, Wagler.
Tiliqua rufescens, Gray.
Eumecus rufescens Wiegmann.
Tiliqua carinata, Gray.
Tiliqua affinis Gray.
Euprepis sebæ, Dumeril et Bibron.

This smooth, snake-like reptile is sometimes called the grass-lizard, as it may be seen darting about in the grass. It frequently enters outhouses, but is rarely seen in the interior of dwellings. There is considerable variety of colouring in different individuals, from which the Karens distinguish three species, but they are probably all varieties of a single species, which is found from the Sandwich Islands to Hindustan. —*Mason.*

POISONOUS SERPENTS.

Venomous serpents are quite numerous, both terrestrial and aquatic; yet during a twenty years residence, not a single fatal case from the bite of a terrestrial serpent has come to my knowledge. —*Mason.*

(6998) *Elaps melanurus,* Elaps.

Syn. Coluber melanurus, Shaw.
Vipera trimaculata, Daudin.
Elaps trimaculatus, Merrem.

This is a small poisonous serpent described by Dr. Cantor as inhabiting the Provinces, but which I have not satisfactorily identified. It has a very small mouth, and rarely bites, but its venom is

said to be "as virulent as that of other venomous serpents."—*Mason.*

(6999) *Fire serpent.* The Elaps is perhaps the "fire serpent" of the Karens so called from the burning produced by its bite, which they say is poisonous, but not fatal. It is the smallest poisonous serpent in the Provinces. According to the Burmese it has a more wonderful power of reproducing itself than the hydra of antiquity. They say if one be killed, two or three others immediately arise in its place, and a Burman, who, I believe, intended to speak the truth, assured me that he once killed one, and immediately he saw two others, close by the dead one, without being able to conjecture whence they came. Its Burman name signifies the "father of many." I have repeatedly had small innocuous serpents brought me for this fire-snake; but when I showed the natives that there were no poisonous fangs, and that no others appeared at the funeral of my specimens, they coolly replied that they were mistaken; they had not brought me the true reptile. Some of the Karens think it a species of trigonocephalus.—*Mason.*

(7000) *Bungarus fasciatus*, Schneider. Yellow-banded bungarus.

Syn. Boa fasciatus Shaw.
Pseudoboa fasciatus, Schneider.
Bungarus annularis, Daudin, Schlegel.
Aspidoclonian.

The bright belted bungarus, a poisonous serpent, with alternate black and yellow bands, is a splendid reptile, often seen in the vicinity of Maulmain. It grows six or eight feet long, and five or six inches in circumference. Its bite is usually deemed fatal, but I knew a Karen woman to be bitten by one in the foot, and she recovered, though after much suffering. The tail terminates in a hard bony point, which the Karens think is a sting.—*Mason.*

(7001) *Bungarus candidus*, Linne. White-banded bungarus.

Syn. Bungarus cœruleus, Daudin.
„ semifasciatus, Kuhl, Schlegel.
Aspidoclanion semifasciatum, Wagler.
Boa lineata, Shaw.
Pseudo-boa cœrulea, Schneider.
Coluber candidus, Linne.

A specimen of another species with white bifurcated bands was killed in Maulmain after making a gallant defence. All the species of this genus are furious snakes when their anger is aroused, and at certain seasons the natives say pursue their antagonists a long distance; although Dr. Cantor confines this characteristic to the hamadryad.—*Mason.*

(7002) *Hamadryas?* Dusky Hamadryad. The natives describe a venomous serpent that grows ten or twelve feet long, with a short, blunt head, a dilatable neck, thick trunk, and short tail. It is of a darker colour than the common cobra, nearly black. I have never seen it, but the description given me accords so well with the generic character of hamadryas, that it must be a species of that genus. "The hamadryas," says Dr. Cantor, "is very fierce, and is always ready not only to attack, but to pursue, when opposed;" this, too, is a conspicuous trait in our Tenasserim serpent. An intelligent Burman told me that a friend of his one day stumbled upon a nest of these serpents, and immediately retreated, but the old female gave chase. The man fled with all speed over hill and dale, dingle and glade, and terror seemed to add wings to his flight, till reaching a small river he plunged in, hoping he had then escaped his fiery enemy, but lo! on reaching the opposite bank, up reared the furious hamadryad, its dilated eyes glistening with rage, ready to bury its fangs in his trembling body. In utter despair he bethought himself of his turban, and in a moment dashed it upon the serpent, which darted upon it like lightning and for some moments wreaked its vengeance in furious bites; after which it returned quietly to its former haunts.—*Mason.*

(7003) *Hamadryas ophiophagus*, Cantor. Belted hamadryad.

Syn. Naja elaps Schlegel.
„ bungarus, „
„ vittata, Elliot.

Karens from Pegue describe a species of hamadryad with black and whitish transverse bands. It is often seen twelve feet long, by a foot in circumference, and one of my informants tells me he has seen them nearly three fathoms long, and proportionately large. It does not appear to be known in these Provinces, but the Burmese and Karens have well established names for the species; and it must be, I think, the above, of Cantor's.—*Mason.*

(7004) *Naja lutescens*, Laurenti. Tenasserim cobra.

Syn. Coluber naja, Linne.

The Tenasserim cobra differs from the described species in the marking of the hood. In the common Indian species (*N. tripudans*) the hood is figured with "a double reversed horseshoe line of black or brown, with the two ends dilated so as to inclose an oval space, in the centre of which is a ring or spot of black." In the Tenasserim species there is only a single oval white ring, edged with black, in the centre of which is a ring or spot of olive-green, the general colour of the snake, but black on the margin. In other respects it does not differ from *N. tripudans*. Cantor has described a species which he calls *N. larvata*—"Brownish, with numerous faint transverse stripes; the hood marked with a white ring, not unlike the form of a mask, behind which there are from three to five white rings; —the anterior part of the lower surface with alternate white and bluish-black rings." This can-

not be our species, for it has none of the additional white rings behind the hood, nor on the lower surface any "transverse stripes." As these are the only Indian cobras described, is not ours a new species? The incantation of serpents has usually been attributed to the power of music, and a late writer remarks that "it is so strange that many have denied the fact, while others have asserted it to be a deception." "Our own conviction," he adds, "is, that serpents are extremely sensitive of impressions from musical notes, or modulations, under the influence of which they wreathe their bodies from feelings of pleasure, while to these graceful contortions and undulating movements, the charmer, who plays on a pipe or some simple instrument, adapts the time." This is the common theory,—that serpents are rendered docile by music. It must however, be abandoned; for with many others I have seen the cobra dance in imitation of its Burmese master, while he sat upon this haunches before it, making the motions with his body and hands that he wished the snake to imitate, and which it did perfectly without any music whatever, or any other sound except an occasional authoritative *hay!* Again, a pair of cobras kept perfect time with their master, while no sounds were uttered and allowed him to handle them as he wished. At his command they danced, and at his command they lay gracefully down as if asleep The Burmese usually put a wild one, which they secure when half or two thirds grown, with a practised tame one. These will dance and wreathe themselves at their master's pleasure. Sometimes darting at him but at that moment he straightens himself up, with his eyes fastened upon the snake's eyes, and in a gruff voice commands them to perform. Following his motions, they stand almost upright with their hoods dilated and their colours all in play as they dance; now swift—now slow—now approaching—now receding;—and I have seen the younger in his receding moments give unequivocal tokens of desiring to make his exit: but on hearing his master's call he turned again though evidently with more reluctance than the old actress. The power of effecting all this is certainly attributable neither to magic nor music. It must, I think, be ascribed to fear, and to a very simple principle—the power of imitation; a power possessed by different animals in different degrees. Serpents are by no means the least docile of the animal kingdom; nor are cobras the most intractable of serpents. Although quite abundant in the Provinces no case of a person's being bitten by one has ever come to my notice, but I have frequently known of individuals having been bitten by the green viper, a serpent which is much readier to bite than the cobra; and one which, it is worthy of remark the serpent charmers do not make use of; the cobra, and the bungarus, being their favourites. The largest cobra I have seen on the Coast measured five feet nine inches. It killed a good dog that attacked it, and was dispatched in the nocturnal melee by Mr. Ramsey, who supposed he had killed a common rat-snake, until he found his dog was mortally wounded.—*Mason.*

(7005) *Viper.* The natives describe a serpent whose poison they say is much more deadly than that of the cobra. It is very short and thick, without a hood, say some, but others state that it can dilate its neck, though not to the extent that the cobra can. The description accords best with a species of viper, but I have never seen it. It is thought to be rare in these Provinces, though abundant in Burmah; and not uncommon in the neighbourhood of Martaban.—*Mason.*

(7006) *Trigonocephalus gramineus*, Shaw. Green viper.

Syn. Trigonocephalus viridis Schlegel.
,, erothrurus. Cantor, (young.)
Coluber gramineus, Shaw.
Vipera viridis, Daudin.
Trimeresurus viridis, Lacepede.
Cophias viridis, Merrem.
Bothrops, Wagler.

This poisonous serpent may be readily distinguished from all the innocuous ones of a similar colour by the head being covered with scales and not with plates. The Karens describe two species, one with a red tail, and the other with a red line down each side, but Dr. Cantor regards them as varieties of the same species. They may be often seen in trees, and their colouring so much resembles the foliage that I have had my hand drawn back by a native when about to lay it on one that I was looking for among the branches, but with no intention of touching the reptile. They appear to bite more frequently than any other venomous terrestrial serpents in the Provinces, but although the limb that is bitten always swells up to a monstrous size and much pain ensues, yet I never heard of a case proving fatal. The natives have a saying to the effect that the part of the limb below the bite is destroyed, but this I very well know to be an error. After recovery, the limb, in the cases that have come to my knowledge remained uninjured.—*Mason.*

(7007) *Hydrus*, vel *Hydrophis*. A species of poisonous water snake abounds in our estuaries and rivers, as far as tide-water ascends. Their bite has proved fatal in every case that has come under my observation, and that too in a very short period after the wound was inflicted. The Burmese, however, tell me that persons do sometimes recover, and that bites in the rains usually prove more fatal than in the dry season. They are exceedingly numerous. At the fishing stakes, near the mouths of rivers, where I have watched the fishermen at their labours, scarcely a draught of fish was drawn up without one or two of these serpents being among them. There are several

species, but I have never examined their specific distinctions; and the Burmese call all One species, with a cylindrical body, the natives say never bites without producing death.—*Mason.*

(7008) *Laticauda scutata.* Flat hydrus. Another pelagic serpent, the Burmese say, has a flat body, and its bite, though poisonous, may be cured by medicine. It is probably this—*Mason.*

(7009) *Hydrus gracilis*, Shaw. Slender sea snake. In the delta of the Irrawady the Karens inform me, a water snake departs and returns with the tide, that is about two yards long, but not thicker than the thumb; and the anterior part of the body is much smaller than the posterior. It is said to coil itself around every object with which it comes in contact. It is probably this—*Mason.*

INNOCUOUS SERPENTS. Innocuous serpents are very numerous, from the diminutive blind-worm that hides itself in its burrow, to the gigantic python that displays its coat of many colours in the tree tops, ready to dart upon any animal that seeks the shade.—*Mason.*

(7010) *Typhlops braminus*, Daudin. Blind worm.

Syn. L'Orvet lombric, Lacepede.
Anguis, Russell.
Punctulated slow-worm, Shaw.
Eryx braminus, Daudin.
Typhlops rondoo talooloo. Cuvier.
Tortrix russelii. Merrem.
Typhlops. ,, Schlegel.
Argyrophis braminus Gray.

The blind worm, or slow worm, belonging to the class of burrowing serpents, is not uncommon but I have seen it dug out its hole in the earth as often as I have met with it on the surface. The popular idea of its being exceedingly poisonous, so common in England, is still more prevalent here, and the natives are much afraid of it. When they are shown its mouth, and its inability to do injury demonstrated, they turn to the pointed excrescence on the tail, and express their confident belief that it has a sting there like the scorpion. Dr Cantor, who appears to have had a specimen from these Provinces, identifies it with *Typhlops braminus*, and gives the synonyms which will be found above; but our reptile differs from any description or figure that I have seen. The upper jaw projects, in a specimen before me, the tenth of an inch beyond the lower, so that the mouth opens quite below the head. The eyes are beneath the skin, through which they are seen, and the scales have each a dark spot on them, so that the general appearance is that of lead coloured spots on a dull-white ground. Lacepede's figure of *Le Lombric* represents it the nearest of any figure I have seen, but there is a horny excrescence at the extremity of the tail, with a conspicuous sharp thorn, not seen in the figure. Dr. Cantor says that of a great number which he examined, the largest was not eight inches long; but a specimen before me measures more than twelve inches in length, and the body an inch and a quarter in circumference. —*Mason.*

(7011) *Python reticulatus.* Schneider. Python.

Syn. La jaune et bleue, Lacepede.
L'oularsawa, Bonnaterre.
Boa reticulata, Schneider, apud Duadin.
,, rhombeata, ,, (?)
,, constrictor. Var. e Latreille.
,, phrygia, Shaw.
Python amethystinus, Daudin.
,, des isles de la Sonde. Merrem.
,, schneiderii, Merrem.
Coluber javanensis, Fleming.
Python javanicus, Kuhl.

A large python, usually called a boa, is not uncommon. I have seen the head of one that was killed by a drove of hogs whose whole length measured eighteen feet, and the natives say they grow much larger. The Karens have an apothegm that the largest python can swallow a full grown buck-rusa or sambur deer, horns and all without inconvenience. They are often seen coiled up among the branches of trees, on the banks of streams in the interior, where they are frequently noosed by Karens, who regard them as valuable food. I have seen a Karen seize one nine feet long by the tail in the water, and with the aid of his associates succeed in capturing him. According to a Karen legend, all the poisonous serpents derive their virulence from the python, which, though innocuous now, was originally the only one that was venomous. In those days he was perfectly white, but having seduced away a man's wife, aunt Ee, [Eve?] he made her, while she was in his den, weave figures on his skin in the forms which are now seen. At that time, if he bit the footstep of a man in the road, such was the virulence of his poison that the man died, how far soever that man might have passed from the bitten track. The python had not, however, any ocular demonstration of the fact, so he said to the crow: "Crow, go and see whether people die or not when I bite the foot-track." The crow went to the neighbourhood of a Karen cabin, and found the people, as is their custom at funerals, laughing, singing, dancing, jumping, and beating drums. He therefore returned to the python and told him, that so far from his efforts producing death, on the contrary they produced joy. The python was so angry when he heard this, that he ascended a tree, and spit up all his venom; but other creeping things came and swallowed it, and people die of their malignancy to this day. The python made them promise, however, not to bite without provocation. The cobra said: "If there be transgression so as to dazzle my eyes, to make my tears fall seven times in one day, I will bite." So said the tiger. The Karens suppose the bite of a tiger

to be as virulent as a serpent's bite and others, and they were allowed to retain their poison. But the water-snake and frog said they would bite with or without cause, as they liked, so the python drove them into the water, where their poison melted away, and their bite became harmless. The tree, however, from which the python spit up his venom became deadly, and its juice is used to this day for the purpose of poisoning arrows. The gall bladder of the python is much sought after by natives for its medicinal virtues, which are in great repute, especially among Karens. The natives say there are two or three species, but all that I have examined belong to one.—*Mason.*

(7012) *Acrochordus javanicus.* Innocuous estuary-serpent. The Burmese describe a harmless snake, strongly resembling the venomous hydrus, and like that inhabiting the estuaries and tide-water streams. I have never seen it, but a Burman who had been bitten by one, said its bite was like the bite of a dog. He described it as about six feet long when full grown, and with a variegated skin. It must be a species of acrochordus, and probably this—*Mason.*

(7013) *Lycodon aulicus*, Linne. Lycodon.

Syn. Lycodon capucinus. Boie.
„ hebe, Schlegel.
„ atropurpureus. Cantor.
Coluber striatus, Shaw ?

A small harmless snake is common at Maulmain, with the head depressed, not very distinct, and lighter or darker chesnut, with numerous white transversal bands on the side forming a network composed of brown scales edged with white." It is of the genus lycodon, but the natives, to whom I have shown specimen, are not united in the name appropriated to it, either in Burman, or Karen.—*Mason.*

(7014) *Coluber radiatus*, Schlegel. Striped rat snake.

Syn. Coluber quadrificatus. Cantor.

A species of coluber, green-yellow on the back, with a broad black longitudinal band, interrupted at intervals, and a narrower one on each side, is often found where rats resort, on which it preys, and hence it is called a rat snake. One that dropt from the roof of my house into the dining-room on being attacked by a cat, defended itself furiously, and came off victorious. I have seen them in the act of swallowing rats twice the circumference of their own bodies.—*Mason.*

(7015) *Coluber korros*, Shaw. Brown-green rat snake. Another snake, with the habits of the preceding, but destitute of its stripes, and brown-green on the back, is common throughout the Provinces. Under certain circumstances the Burmans say the bite of this serpent is fatal. These are five: *gnang-soung, loo-soung, young-soung, lan-soung, ne-soung.* "Snake oblique, man oblique, turban oblique, road oblique, and sun oblique." That is, if the snake approaches a man with its head askance, as this snake is always said to do, and the man look at it askance, and if his turban be put askance, and he be moving on the road askance, and the sun be askance descending in the heavens; when these five circumstances meet, if the snake bite, which by the way is always very improbable, death will certainly ensue!—*Mason.*

(7016) *Coluber nasutus*, Shaw. Ribbon snake.

Syn. Dryinus nasutus, Bell.
„ prasinus, Reinwardt.
Dryophis „ „
Tragops, „ Wagler.
Passerita, „ Gray.
Dryiphis prasina, Schlegel.

This tree snake, is grass-green all over from the head to the tail, excepting the under lips and throat which are whitish, and a white line on each side which divides the upper from the under parts, or the scales from the scuta and scutella. The skin under the scales is black, alternating with light blue, and these colours play between the scales when the snake is struck. The head is long and attenuated, and the upper jaw, which is longer than the lower, is slighly recurved with a small snout of a curved plate. There are fifteen rows of imbricated rhomboidal scales on the body, the rhomboidal form of the scales appearing most distinct on the tail. It is probably *Dryinus nasutus*, of which I have no description, and although it differs in some respects from Cantor's description of *D. prasinus*, I presume it is a variety of the same species. The whole length of a specimen before me is four feet four inches, of which the tail is one foot six inches.—*Mason.*

(7017) *Dipsas cynodon.* Variegated tree snake. A tree snake, with a cordate head much wider than the neck and body, is not uncommon. It is covered with brownish black spots, but may be best recognized by "a dark, black-edged, arrow-shaped mark" on the head, and a black oblique streak from the eyes to the nape of the neck."—*Mason.*

(7018) *Dipsas multimaculatus.* Dr. Cantor describes a second, and nearly related species from the Provinces.—*Mason.*

(7019) *Tropidonotus stolatus*, Linne Buff-Striped Tropidonotus.

Syn. Coluber stolatus, Linne.
Le chaygne, Daubenton, Lacepede.
La vipere chapgne, Latreille.
Coluber tæniolatus, Daudin.
Natrix stolatus, Merrem.

This is a small aquatic snake, with black bars across the body, interrupted by a buff-coloured, longitudinal band on each side, common in the paddy fields around Maulmain.—*Mason.*

(7020) *Tropidonotus schistosus* Black-Striped Tropidonotus.

Syn. Tropidonotus mœstus, Cantor.
Coluber schistosus, Daudin.
„ surgens, Cantor.

This is a darker colored species than the preceding, and has an obscure black line down each side. When attacked it distends its neck like a cobra, but to a less extent, and they are sometimes mistaken for cobras. Half a dozen natives who had seen an individual display this power, would not be convinced, but the reptile was a cobra, although they saw the snake's mouth was destitute of fangs.—*Mason.*

(7021) *Homalopsis rhinchops*, Schneider. Water snake.

Syn. Hydrus rhinchops, Schneider.
Boa molaroides, „
Elaps boæformis, „
Enhydrus rhynchops, Latreille.
Hydrus cinereus, Shaw.
Hurria schneideriana. Daudin.
Coluber schneiderianus, Daudin.
„ cerberus, Daudin.
Python rhynchops, Merrem.
„ clapiformis, „
„ molarus. „
Coluber obtusatus, Reinwardt.
Cerberus (Homalopsis obtusatus) Cuvier.
Homalopsis schneiderii. Schlegel.
Cerberus cinereus, Cantor.

Innocuous water snakes of the genus homalopsis, are very abundant. viz.

Erpeton, Lacepede.
Rhinopirus, Merrem.
Pseuderyx, Fitzinger.
Cerberus, Cuvier.
Hypsirhina, Wagler.
Hydrops, „
Helicops, „
Potamophis, Cantor.

I have noticed three distinct species at Maulmain, all of which are called by the Burmese *yayhmwey*, or water snakes, while the poisonous aquatic serpents are called *gyat*. It becomes an inexperienced observer however, not to trust implicitly to the natives, for they often handle the venomous ones as carelessly as if they were harmless; and at other times they will stone an innocuous one as if its bite were fatal. One species is of a dark grey, or olive-green colour on the back, and white on the belly, with transversed black bands.—*Mason.*

(7022) *Homalopsis enhydris*, Schneider. Iridescent Water-Snake.

Syn. Hydrus enhydris, Schneider.
Enhydris cœrulea, Latreille,
Hydrus atrocœruleus, Shaw.
Coluber pythonissa, Daudin.
Hypsirhina, Wagler.
Potamophis lushingtonii, Cantor.
Homalopsis aer, Schlegel.
„ olivaceus, Cantor.

An allied species is not rare, which is "iridescent dark greenish, or brownish olive above, the scales edged with black; in some two parallel light grayish lines from between the eyes to the tip of the tail." It has the same native names as the preceding species.—*Mason.*

(7023) *Naked serpents.* According to Cuvier the cæcelia tribe of reptiles are naked serpents. —*Mason.*

(7024) *Cœcelia*? Cæcelia. The cæcelia can be easily distinguished from an earth-worm when it opens its serpent-like mouth, but in ordinary circumstances it will be considered an earth-worm. A species with a longitudinal band on each side is quite common.—*Mason.*

FROG TRIBE.

The Karens have distinctive names for fourteen different species of frogs and toads, but I have paid them very little attention.—*Mason.*

(7025) *Rana tigrina*, Daudin. Tiger Frog.

Syn. Rana mugiens. Latreille.
La grenouille taureau, Cuvier.
Rana limnocharis, Boie, MS.
„ cancrivora, Gravenhorst.
„ picta „
„ brama, Lesson.
„ rugulosa, Wiegmann.
„ vittegera, „

One of the largest species of frogs in the Provinces is—*Mason.*

(7026) *Polypedatus.* Tree frog. Of a tree frog that I sent Mr. Blyth he wrote: "The tree frog is a species of polypedatus, which I have previously received from Arracan and Assam."—*Mason.*

(7027) *Hyla bengalensis*, Gray. Bengal tree frog.

Syn. Polypedatus;

Another species that I sent him he said was this.—*Mason.*

(7028) *Bufo melanostictus.* Schneider. Toad.

Syn. Bufo bengalensis, Daudin,
„ scaber, Latreille.
„ dubia, Shaw.
„ carinatus, Gray.

A large toad which I have seen the Burmese doctors bringing into town, bound hand and foot, "for medicine," is not uncommon.—*Mason.*

(7029) RESEDA ODORATA is the common Mignonette. It has lanceolate bluntish entire or trifid leaves; a 6-parted calyx equal in length to the petals, which are finely cleft into many club-shaped divisions, the two lowest simple, the capsules 3-toothed. It is a native of the North of Africa and Egypt, but its delicious fragrance has caused it to be cultivated all over the world. It is naturally an herb, but when trained in the greenhouse it becomes shrubby. The arborescent form of this plant is called Tree-Mignonette.—*Eng. Cyc.* There are many species of

the genus, Reseda, most of which are natives of the South of Europe and Egypt. In India, this sweet-scented little plant may be cultivated throughout the year, only requiring moderate care in watering; and when the blossoms have passed their maturity, cut down the shoots, when fresh ones will spring up. If you require the seed, observe, as soon as the capsules are full, to pick off the branches and let them dry; otherwise if let remain on the plant, they drop out and are lost. It loses much of its fragrance, if grown in too rich a soil. Is propagated by seed, either in pots or beds; each plant should be about from four to five inches apart.—*Riddell.*

(7030) RESEDACEÆ, a natural order of Plants belonging to the class of Exogens. This order embraces the genera *Reseda, Ochradenus, Oligomeris, Holopetalum, Astrocarpus* and *Caylusea.—Eng. Cyc.*

7031) RESINS. Resinous substances are found in greater or less abundance in most plants. Many of them exude naturally from fissures in the bark or in the wood, or they are obtained from incisions made in certain trees and shrubs. As they exude they are commonly mixed with an essential oil, which either evaporates on coming in contact with the air, or is resinified by the action of oxygen. Such mixtures of volatile or essential oil with resins are sometimes called *balsams* [See BALSAM]. When gum is mixed with resins another class of substances is produced, called *gum-resins.* [See GUM-RESINS]. The resins when pure and free from essential oil have no odour except when rubbed or heated. Their colours are pale yellow or brown; they are good insulators, and become electric by friction. Most of them are heavier than water, insoluble in that fluid; they have little or no taste, but those which have distinctive flavor derive them from minute portions of some non resinous body. They are usually softened or even fused by being boiled in water, and some of them in such a case pass into hydrates. They are inflammable, burning in the air with a sooty flame, and yielding by dry distillation volatile liquids and inflammable gases. The natural resins are usually composed of two or more resinous substances which may be separated by the action of alcohol, in which most resins are soluble. They are also mostly soluble in ether in sulphuret of carbon and in the fat and volatile oils. Alcoholic solutions of many of the resins act the part of feeble acids, reddening litmus paper, and combining with and neutralizing acids. These compounds are termed *resinates* or *resin-soaps*, and are distinguished from *oil-soaps* by not forming a gelatinous emulsion when concentrated, and by not being separable from water by the addition of common salt: they are, however, detergent and form soap like common soap. [See SOAP.] Others are indifferent either as an acid or a base, but there are a few which are regarded as *basic*. The resins are thrown down from their alcoholic solutions by the addition of water, the white pulverulent or curdy precipitate forming the *magistery* of the old chemists. The alcoholic solution of the acid resins is not precipitated by ammonia; but the precipitate thrown down by the addition of water is soluble in solution of ammonia. The alcoholic solution of the indifferent resins is precipitated by ammonia. The acid resins may also be distinguished by the crystalline precipitate produced by the addition of their ammonio-chloride solutions to nitrate of silver. Some of the resins dissolve in sulphuric acid without decomposition in the cold, and they are precipitated by the addition of water; but if heat be applied sulphurous and carbonic acids are disengaged, and a carbonaceous mass is obtained mingled with another substance which has been improperly named *artificial tannine.* The action of nitric acid upon resins leads to the formation of various new products. Acetic acid dissolves many of the resins, as does also muriatic when concentrated. The resins have been considered as oxides of definite hydrocarbons but their analysis is very imperfect and will be further noticed under TURPENTINE.—*Tomlinson.* For the Madras Exhibition of 1855 a fragrant Resin from the Bababooden Hills Mysore, was forwarded by Mr. R. D. Meppen, the leaves sent appear to belong to one of the Dipterocarpeæ. A green semi-transparent hard resin from Coorg, was soluble in spirit, and promised to make excellent coach varnish, the tree is not known.—*M.E.J.R.* Resins are solid, brittle, of a certain degree of transparency, and colour common to yellow. When pure, they are

(7017) *Dipsas* [illegible] and in oils, but not in water. They differ from gums. The

A tree snake, with than the neck and body is covered with brownish black spots, and is best recognized by "a dark, black, arrow-shaped mark" on the head, and [illegible] streak from the [illegible] eye."—*Mason.*

(7032) *Resins Gum-resins, Gutta percha and Gum-Elastics, of Eastern and Southern Asia.* Under this head are included the following:

1. Piney or Valeria.
2. Canarium: and.
3. Vatica or Shorea, all known as dammer.
4. Kino.
5. Lac.
6. Dikkamaly.

7. Benjamin.	11. Aloes.
8. Myrrh.	12. Gamboge, &c.
9. Poon-yet.	&c. &c.
10. Mutti-pal.	

The most important of all the solid resins produced in India are those which are included under the general name of "Dammer," and it will be the chief object of this report to clear up the doubts which have hitherto existed, as to what particular trees yield each of the crude products found in the bazars. It will therefore be advisable to quote the various authorities on the subject, before proceeding to show the result of the Jury's investigations.

Ainslie, speaking of "dammer or Indian resin" which he refers to the *Chloroxylon dupada* of Buchanan (the *Vateria indica* of Linnæus,) says:—"Of the substance usually termed dammer and improperly country rosin, there are three sorts to be met with in the bazars, called in Tamil "*vullay coonghilium*." "*curpoo coonghilium*" and "*noray coonghilium*," or white, black, and coarse dammer. It much resembles the resin obtained by distillation from the turpentine of the *Pinus sylvestris*, both in appearance and natural qualities, and would seem to be a common product of many asiatic countries. I perceive it is to be procured in great abundance in Sumatra from a tree called by the Malays "Canari." (*Dammara nigra legitima* of Rumphius.) The "Canari," we may observe is the *Canarium* of Roxburgh and yields the black dammer of the Western coast of India. In Java, Borneo, Joanna and several of the Sooloo islands, dammer is quite common, and a regular export to the continent of India. The coarse or stony kind, the Malays call "dammer batu" and the Javanese "dammer selo," the white or fine sort they term "dammer putch." * * * * * * Dr. Buchanan Hamilton in his interesting "Journey through Mysore" informs us that he found the tree which yields dammer growing in the woods of Malabar, and in the mountainous tracts which separate the Travancore country from the Madura district, and bestowed on it the scientific name of *Chloroxylon dupada*, though Ainslie then knew well that the greater part of the dammer met with in India, is an import from more Eastern countries. How far, he adds, the "*Chlorozylon dupada*" differs from the *Dammara nigra legitima* of Rumphius, I regret to say I am not now prepared to state," * * * * * * * The tree to which Dr. Buchanan gave this name of Chloroxylon dupada had been already described by Linnæus under the name of *Vateria Indica*, which it still retains. The specific name *dupada* was derived by Dr. Buchanan from the Canarese name "dupa," applied to this, and probably to other species of the Vateria growing in Mysore and the Western Coast. It may also be noted that the *Canarium strictum*, called by way of distinction the "black dammer tree" also grows in precisely the same locality and bears such a general resemblance in the color and shape of its leaves and growth to the Vateria, that it can only be distinguished on a somewhat close inspection. From this circumstance, no doubt, arose the belief that both the white and black dammers were produced from the same tree, and as the few which Dr. Buchanan saw were probably *Vaterias*, he naturally concluded that this tree alone yielded both species of dammer.

In short, omitting what refers to foreign products with which we have no immediate concern, the whole of Ainslie's remarks may be briefly summed up as follows—Ainslie's "Curpoo Coonghilium" is doubtless the product of the *Canarium* of Sumatra and the Western coast of India, whilst his other two sorts may be either the products of the *Vateria* or *Shorea*, probably both. The three varieties are *not* the produce of the *same* tree, as Ainslie seems to have supposed. His *vuelay* and *noray coonghilium* or white and coarse dammer, supposing them to be the products of the western coast and derived from this Chloroxylon dupda—the white dammers of the northern Circars which will be considered hereafter are derived from the Shoreas—are the products of the Vateria Indica of Linnæus (the *Chloroxylon dupada* of Buchanan), which is the *Dupa maram* of the Canarese, the *Chadacula* of the Tamools, and the *Payanee* or *Piney* of Malabar. His *curpoo coonghilium* or black dammer is the product of the *Canarium* of Roxb. and Wight, the *dammara nigra legitima* of Rumphius, and the *Canari* of the Malays. Roxburgh's description of the principal resiniferous trees of India is here given as extracted from O'Shaughnessy's Bengal Dispensatory.

(7033) *Vateria Indica*—*Linn.*

Chloroxylon Dupada, Ham.	Chadacula, Tam.
Piney marum Tam.	Tayanee, Malabar.
Dupa marum, Can.	

This is a very large and stately tree, a native of Malabar, and lately found also in Mysore. The young shoots and all tender parts except the leaves are covered with fine stellate pubescence, leaves alternate, petioled, oblong, entire, from emarginate to obtuse, pointed, smooth, coriaceous, from four to eight inches long and two to four broad, petioles round about an inch long; stipules oblong, panicles terminal, ramifications rather remote; flowers rather remote, pedicelled, pretty large; bractes oblong, one flowered; clayx five, cleft to the base, divisions oblong, obtuse, villous on the outside, corolla five petalled, petals oval, emarginate, broader but very little longer than divisions of the calyx, filaments from 40 to 50, short, broad inserted between the petals and the base of the germ, anthers linear with a single filiform beak; germ superior, conic, downy, three celled, cells con-

taining 3 ovules each, attached to the top of the axis, style longer than the stamens, stigma acute, pericarpium acoriaceous, fleshy, oblong, obtuse, one-celled, three-valved capsule, general size about 2½ inches long and 1½ in diameter, seed solitary of same shape as the capsule. (*Roxb. Fl. Ind. p* 601). The substance called "East Indian copal" and sold in England as gum *anime* exudes abundantly from this tree It occurs of all shades of color between pale green and deep yellow: the finest pieces are called *kahroba*, Arabic Amber, and sold as *amber* in the bazars of Bengal; the resin before it hardens is the Piney varnish of Malabar. Besides the uses already alluded to, candles are made of this resin in Malabar, which Dr. Wight informs us, diffuse in burning an agreeable fragrance, give a fine clear light, with little smoke, and consume the wick without snuffing. These candles were at one time introduced into England, but a very high duty having been imposed the trade ceased.

(7034) *Canarium commune.* (*Roxb. Fl. Ind. Vol.* iii *p.* 137.) A native of the continent of India, the Archipelago and Isle of France, where it is called "Bois de Colophane." It was brought from the Moluccas to the Calcutta Botanic garden, but in Roxburgh's time did not thrive, owing to the coldness of the winter months. The bark yields an abundance of limpid oil with a pungent turpentine smell, congealing into a buttery camphoraceous mass.

(7035) *Canarium Bengalense*, another species, yields a large quantity of very pure, clear amber-colored resin which soon becomes hard and brittle, and is not unlike copal; yet the natives of Northern India, set little or no value upon it. In the Calcutta bazar it sells at 2 to 3 Rs. per maund of 86 lbs. It is a native of Sylhet and the adjacent mountainous countries and flowers in May and June.

The dammer of the Northern Circars is chiefly produced by the varieties of the genus Shorea. The *Shoreas* are also found growing to a very limited extent on the Western coast, but do not appear to produce much, if indeed any, of the resin collected for sale.—O'Shaughnessy, gives the following description of the

(7036) *Shorea robusta or Saul tree.* This is a tree of great size, a native of Morung, the Paulghaut mountains &c. Sepals afterwards changing into 5 long wings, petals 5, stamens 15, filaments capillary below the anthers, anther cells short, obtuse, connectum filiform, produced beyond the cells into a more or less elongated colored, deciduous bristle, ovarium 3 celled, with two pendulous ovules in each cell. Seed solitary, cotyledons stalked, not crumbled, radicle superior, leaves coriaceous, oblong, obtuse, often emarginate at the base, panicles numerous from the axils of the fallen leaves, branches and pedicels glabrous.

The *Shorea robusta*, and indeed some othe species, yield abundance of the resin calle dammer, the superior kinds of which are ei ficient substitutes for the pine resin of th European Pharmacopœia. Captain Jenkins c Assam forwarded specimens of this re sin perfectly transparent and colorless; in th bazars the color ranges from pale amber t dark brown. It is devoid of taste and smell Sp. gr. 1.097 to 1.123, easily fusible, partiall soluble in alcohol (83.1 per 1000), almost en tirely in ether, perfectly in oil of turpentin and the fixed oils; sulphuric acid dissolves an gives it a red color. Two parts of colorles dammer and 2½ parts of oil of turpentine make the best varnish for lithographic draw ings.

(7037) *Dipterocarpeæ.* Dr. Wight gives des criptions of the resiniferous and balsamiferou trees of India. Under the head *Dipterocarpe* he observes:—The trees of this order growing i Madras are all natives of the hilly tracts of th Balaghaut. In Silhet, Chittagong and Peg where they abound, they occupy the plains. I Java one species (*Dipterocarpus littoralis*) i found on the sea shore. A *Hopea* and the *Vateri indica* also approach the coast in Malabar, but th latter, or perhaps a distinct species, is also plenti ful in Mysore. Two or three species are found i Goomsur, forming extensive forests, and affordin to the inhabitants incense, dammer and wood oil Judging from the imperfect specimens collecte by Dr. Maxwell and Capt. McPherson, one o them belongs to Roxburgh's genus *Shorea*, ap parently *S. robusta*. Both these Gentlemen men tion *Chloroxylon dupada* as being one of them, bu this, Dr. Wight thinks, must be a mistake, origi nating in a statement of Dr. Ainslie, that thi is the botanical name given to the Indian dammc tree by Dr. Buchanan, but which was an error o Buchanan's, arising from his not being awar that several trees produce dammer and that hi *Chloroxylon dupada* had already been describe by Linnæus under the generic name of *Vateria* The Shoreas (Roxb.) or Vaticas (Linn) an Vaterias yield the solid product called damme and Piney, whilst the produce of the Dipterocarpu retains its fluidity and is the "wood oil" of th bazars. The Camphor tree of Sumatra is a spe cies of *Vatica*. (*Shorea camphorifera. Roxb.*) Th Vateria Indica (*Chloroxylon dupada* of Buchana and Ainslie, and the Piney marum of the Hindoos produces a resin resembling Copal, much finer than that procured from other species, natives o India, the finer specimens of which are as trans parent as amber and nearly colorless. It is pro cured by the very simple process of cutting a notch in the tree sloping inwards and downwards. This is soon filled with the juice, which in a short time hardens by exposure to the air.

(7038) *Canarium.* Under the head of "*Canar ium*," Wight observes,—the resinous juice o

the *Canarium commune* has properties similar to Copaiva, while on the other hand the kernels of the seed afford by expression a bland edible oil. The *Canarium strictum* of Roxburgh is known in Malabar under the name of the "black dammer tree" in contradistinction to the *Vateria* which is the "white dammer tree." This tree is rather common in the Alpine forests about Courtallum in the Tinnevelly district, and is there regularly rented for the sake of its dammer. The dammer is transparent and of a deep brownish yellow or amber color, when held between the eye and the light, but when adhering to the tree has a bright shining black appearance. The flowers of the species I have not seen, the fruit is a very hard three celled oval nut tapering at each end."—*Wight, Ill.*

In the Madras Exhibition of 1857, the Jury endeavoured to identify the various products and to arrange them under their several heads.

E. J. Waring, Esq., remarks; that "the substances known as "*black dammer*," and "*white dammer*" are undoubtedly the produce of different trees. The *Black dammer* tree, he adds, appears to be the *Canarium strictum* (Roxb. Fl. Ind. Vol. iii. *p.*, 188). It does not grow on the low lands of Travancore, being only found in the mountainous regions between Travancore and Tinnevelly. General Cullen, who has paid much attention to this subject, has never heard of the true Saul tree (*V. robusta*) in the Travancore forests, but the *Vatica tumbugaia* is common in Travancore, it is called Tumbagum or "Cumbagum" and at Courtallum "Congo." The *white dammer*, or vullay coonghilium of Ainslie, is, he thinks, without doubt the produce of the *Vateria indica*. I send you two specimens of the resin very different in appearance, one dense with a vitreous fracture and of a pale green color, the other very porous or vesicular of a bright amber color. I am assured by those who have the best opportunities of knowing, that they are both obtained from the *Peyni marram* or *Vateria indica*, the denser one being the natural exudation which has spontaneously hardened on the tree, and its surface you will perceive bears witness to the fact, whilst the other has been obtained by incision and subsequent exposure to the sun or fire to hasten the hardening process. All kinds of *vellay coonghilium* or white dammers that I have met with on the Western coast are referable to one of these specimens, the difference arising from the mode of collection, and perhaps depending somewhat on the age of the tree. As far as I can learn, there are no other trees in Travancore which yield dammers of any kind."

In a subsequent letter the same gentleman observes, "When last I wrote, I spoke confidently of the white dammer being the exudation of the *Vateria indica*. From subsequent enquiries, this opinion must, I think, be slightly modified, as I am assured by one of the largest collectors of this article to the north (near Cochin) that much of the difference observed in different specimens arises from the *kind* of Piney marum from which they are obtained. The one kind he describes as having longer, narrower and thinner leaves than the common Pinney maram (*Vateria indica*). I have never seen the tree myself but probably it is the *Vateria lanceolata*. In speaking of the "white dammer tree" therefore, it would be perhaps advisable to say, "*Vateria Indica and allied species.*"

Subsequently to this, on the 18th May, in advising the committee of the transmission of specimens of the white and black dammer trees [collected personally by J. Brown, Esq., Astronomer in charge of the Trivandrum Observatory,] Dr. Waring says, "I regret that there are no flowers to the specimens of the black dammer tree, but the fruit and arrangement of the leaves at once prove that it is *not* a Dipterocarpus, and consequently *not* the *Vatica tumbugaia*, whilst at the same time it appears to me clearly to be a *Canarium*. [The specimen was identified by the Jury, as the *Canarium strictum*, Roxb.] I send you Mr. Brown's interesting letter which accompanied the specimens. Regarding these Mr. Brown writes, "It seemed to me that if there was still a doubt as to the black dammer tree," it must have been due to want of authority in the specimens produced, and thinking that I could not help you well by such proxy as I could have obtained, and as I expected to be near the base of the Ghauts and in the region of Dammer trees within a fortnight, I the more readily postponed the matter. The "black dammer tree" was in flower about the beginning of April, as far as I could guess from the seed vessels, and the white dammer tree in the beginning of May. Both trees grow in the forests here, about 1800 feet above the level of the sea, but the white dammer tree seems more common than the other, perhaps because the hill men, getting more dammer from the latter destroy it more readily. The best specimens of the *black dammer* tree which I examined* were above two yards in girth at the height of four feet above the spread of the roots. The trunk is round, straight and smooth, rising 22 to 30 feet before branching, the bark generally whitish, dotted with small papillæ, peels off in long flakes. The dammer that exudes from the cuts in the trunk seems to be a great favorite of several species of insects especially of one resembling a bee, called by the Hill men "kullada" (*earth hole*),* which live in pairs

* This curious circumstance will doubtless account for the mode of formation of the resin called in Burmah

in holes in the ground. I send you specimens of the bark as well as of the black dammer taken by me from one of the trees. The Hill men to get the dammer, make a great number of *vertical* cuts into the bark, all round near the base of the trunk; they then set fire to the tree below the cuts, and having thus killed it, they leave it for *two* years before they collect the dammer," they say that after one year only the quantity of dammer is *much* less than after two years. The tree is killed in the hot season and the dammer is collected in February or March. When on the ghats previously, as well as this year, we were struck on looking towards the forests on both the Eastern and Western slopes as high as 3900 feet above the level of the sea, by numbers of trees with bright red, often crimson foliage, contrasting strongly with the various greens around. These crimson trees, are black dammer trees, the color, due to the young leaves, disappears gradually in April. The leaves of the young plants are more sharply serrated than those of the old trees, and they have tufts of hairs all around the edges, which are not visible in the leaves taken from the old trees. The *white dammer* tree has much the same *tenue*, trunk round and straight, branching at 20 to 30 feet from the ground; its appearance is however sufficiently different. The trunk of the black dammer tree is smooth and whitish: that of the white dammer tree is (in all the specimens I saw) beautifully variegated by variously colored lichens, red, white, green, and black, the latter generally prevailing. The trunk also is *dimpled* all over by the scaling off of small patches of the bark. I am told that the young leaves are also reddish but not nearly so bright as those of the black dammer tree. The white dammer is obtained in the same manner as the black dammer, but the quantity obtained from one tree is generally little more than one third of that from a black dammer tree of the same size. The quantity obtained from a black dammer tree may be about 30 to 40 dungallies. A dungally is a measure of about 2½ seers. Kistniah, Assistant supervisor of the Coimbatore district writing from Suttymungalam says:—"Both the white and black dammer trees grow in these forests, but the black are by far the most numerous being in the proportion of ten to one white dammer tree. Both trees have the same appearance, growing to the height of 10 or 12 yards of one uniform thickness, and then branching like a jack tree. The dammer is extracted from the black dammer tree by piling firewood to the height of one yard around the base of the trunk and lighting it. The dammer subsequently exudes from the trunk as high as the flames reach. The operation is conducted at any season of the year, and the dammer continues to flow for ten years between the months of April and November and is collected in January. The tree after having yielded dammer for 10 or 12 years dies. The white dammer tree is not acted on by fire but the resin exudes spontaneously, and is found at the foot of the trunk, it is not much sought after by merchants."

The Jury remark that both the white and black dammer trees have been recognised (by the specimens) as the *Vateria* and *Canarium*, although the black dammer sent from the Travancore district to the Exhibition was erroneously attributed to the *Vatica tumbugaia* by the exhibitor. Mr. Pedre Proboo ascribes the different appearance of various specimens of this resin to the age of the tree. The most vesicular specimens, he says, are obtained from the young tree, the more compact ones from the mature plant, whilst the darkest colored kinds are obtained from the hearts of the tree when decayed and split with old age.

The Jury sum up in the following few words:—The whole of the substances commonly called "DAMMERS," produced in the Madras presidency are obtained from trees of the genera *Vateria, Canarium, and Shorea or Vatica*. The two former viz. Vateria and Canarium, yield by far the largest part (if not the whole) of the dammers produced on the Western coast of the Peninsula, whilst the Shoreas or Vaticas yield the greater part of that collected in the northern and eastern districts.

They may be briefly arranged as follows.—

(7039) *Dammers of the Western Coast. Black Dammer.* (*Canarium strictum*), the *carpoo coonghilium* of Ainslie, the *Dammara nigra legitima* of Rumphius and the *Canari* of the Malays. This occurs in large stalactytic-shaped masses, of a bright shining black color when viewed from a distance, but translucent and of a deep reddish brown when held in thin laminæ between the eye and the light. It is perfectly homogenous, and has a vitreous fracture. Its shape appears to be due to the fact of the balsam having exuded in a very fluid state and trickled down the trunk of the tree, where it gradually hardens by exposure to the sun the fresh resin continuing to flow over that already hardened, gives rise to the stalactytic appearance of the huge lumps of resin, the outside of which much resemble the guttering of wax caused by placing a lighted candle

"Poon-yet" and "Poey-ne-yet," specimens of which were exhibited at the Madras Exhibition of 1857, and are said to be found in the ground, and were supposed to be produced by some hymenopterous insect, it is also found in hollow trees. This substance, although composed chiefly of a yellow brittle resin mixed with more or less sand or earth, has an appearance precisely like that which would be looked for if used by an hymenopterous insect in the construction of its cells. (See classified Catalogue of the Madras Exhibition of 1857. class iv.) The Madras Exhibition of 1855 contained a substance from Malacca called "*Dammer klootee*" which had been evidently formed in the same manner, although the cells were larger and the resin blacker and harder than the Poonyet.

n a draught. It is insoluble in cold, but partially soluble in boiling alcohol on the addition of camphor: when powdered it is readily soluble in oil of turpentine. Powdered and burnt on the fire it emits a more resinous smell and burns with more smoke than white dammer. The size of the lumps of this resin, together with its color and the peculiarity of shape already mentioned, suffice to distinguish it from other Indian resins.

(7040) *White Dammer or Piney resin* (*Vateria indica and allied species*) of Linnæus and Wight. *Choloroxylon Dupada* of Buchanan and Ainslie, the *Doopada* resin of Mysore, and the *Payanee* or *Piney* of the Malabars.

Variety No. 1. *Compact Piney resin or first sort white dammer.*

This occurs in large lumps of all shapes and varying in color on the outside from a bright orange to a dull yellow, bearing evident marks of having adhered to the bark of the tree. It has a shining vitreous fracture, is very hard and bears a great resemblance to amber. Its color (internally) is of all shades, from a light green to a light yellow, the green tint predominating in the generality of specimens.—It is more soluble in alcohol than black dammer, and burns with less smoke and a more agreeable odour.

It is easily distinguishable from all other Indian resins by its superior hardness, its colour and amber like appearance.

Variety No. 2. *Cellular Piney resin, or second or white dammer.*

This occurs either in small lumps or in large masses, generally of a shining appearance and balsamic smell. Has a very cellular structure, which is attributable partly to the mode of collection, and partly to the age of the tree. Notches being cut in the trunk of the tree sloping inwards and downwards the resin collects in the cavity and is either permitted to dry on the spot, or is collected and dried by the application of heat. It is of all shades from light green to light yellow or white, and is usually translucent. Specimens are sometimes seen, in which, from the dessication having been improperly conducted, the resin is more opaque, of a dull green color and full of air bubbles, presenting the appearance of having undergone a partial fermentation. This resin may be recognised by its cellular appearance and balsamic smell—this latter however, (which is of course due to the volatile oil it contains,) is gradually lost by long keeping or constant exposure to the air. On splitting open old and decayed trees, portions of a dark colored resin, are often found having the solid consistence of first variety, but the inferior quality of the second.

(7041) *Dammers of the northern and eastern Distr icts.*

Variety No. 3. *Saul tree dammer.* (*Shorea robusta and other species*).*

This occurs in sticks much resembling in shape the black dammer; but differing widely in colour and consistency. In colour it varies from a light yellow to a dark brown, the two colours being very frequently blended in the same lump and giving it the appearance of having a regular "grain". It is friable and differs from the white dammer of the western coast in its inferior hardness, its opacity and its peculiar form, and from the black *dammer in its color.* An intelligent native correspondent writing from Gopalpore says, "There are extensive tracts of Googulam (*Vatica*) jungles in the Goomsur and Cuttack provinces. The Khoonds and Woodias living in and near these jungles wound trees in several places. The resin issues and is collected when sufficiently solid. The Dammer collected from the decayed parts of the tree is of a dark color, the tree is called "Guggilam" in Telugu and "tala gotso" in Urya. The Khoonds and Uryas make these leaves into the plates from which they eat their food, and also roll up tobacco in them to smoke like a cheroot. In time of famine the above tribes live on a soup made from the fruit of this tree.

(7042) *Lac.* The specimens exhibited, consisted of, *Lac*: Good *stick lacs* were shown from Malabar, Bellary, Mangalore and Pegu Also an excellent series of stick, seed, and shell lac, with the dye from Mirzapore, Kymoor and Hazarebaugh jungles, from Claud H. Brown Esq., for which honorable mention was awarded.

(7043) *Piney resin, or white Dammer* (*Vateria Indica*). Of the many specimens exhibited the best was that shown by E. B. Thomas, Esq. of Coimbatore. It had the amber like appearance of the best description of Vateria resin. Another specimen closely approaching to this in quality was exhibited by Pedre Proboo of Mangalore. He also exhibited a series of specimens of this resin of various qualities and a cake of the inspissated juice of the same tree, which is used for mixing with bees wax in making candles.

Mr. Bassano, tahsildar of Wynaad, exhibits a bottle of the fresh resin, or as it is called Pynie *varnish.* It is of a light grey colour, with a strong balsamic odour. The Tahsildar of Walloo-wynaud in Malabar forwarded another series, varying in color from white to black. The Exhibitor observes that the resin which first exudes is called "*Chengilium*" (this is white), that which flows subsequently is termed "*Coongilium*" (darker than the above), and when dried it is called *Dammer* (black.) He

* The Vatica tumbugaia grows also to a limited extent on the West coast, but yields little if any of the dammer collected there.

describes the three sorts as being the produce of the Payuee tree (*Valeria*).

(7044) *Doona*, Mr. Thwaites of the Government Botanical Gardens at Paradenia in Ceylon exhibited a fine specimen of *Doona dammer*, obtained from a Dipterocarpus tree discovered by the exhibitor and named by him *Doona Zeylanica*. This highly interesting product, in color and appearance much resembles pine resin.

(7045) *Poon-yet*. Specimens of this curious substance were exhibited by Dr. Cleghorn and the Honorable W. Elliot, Esq. They were brought from Burmah and are said to be produced by a species of hymenopterous insect in holes in the ground and hollow trees. Indeed the cellular structure of the specimens much resemble that of a wasp's nest. A circumstance so unusual rendered the Jury at first somewhat incredulous of the correctness of this statement, but in the course of the investigations into the origin of the dammers of the western coast, it was incidentally mentioned that a species of bee appeared exceedingly fond of the liquid dammer of the *Canarium*, this insect lives in holes in the ground and it will probably be found on inspection that its cells are composed of a similar substance to that now under consideration.

(7046) *Kino* (Pterocarpus marsupium.) The several specimens of kino at the Exhibition, said to be the produce of the Pterocarpus marsupium agreed in being but slightly astringent, of a vitreous fracture and very deep red color approaching to black. The finest specimen was that exhibited by Dr. Waring, run in a bamboo.

(7047) *Dragon's blood*, specimens of dragon's blood one in lump and one in reed, neither astringent.

(7048) *Palas or Dhak kino*. (*Butea frondosa*.) Shown by several exhibitors.

(7049) *Dikkamalay* (*Gardenia*). Gardenia resins.

(7050) *Benjamin*. Of two excellent specimens of Benjamin, that of Siam appears to be superior in fragrance to the Sumatra product, although both possess a delightful aroma, they are of the amygdaloid kind, the latter being almost entirely composed of agglutinated white tears.

(7051) *Gunda feroza* (*Boswellia thurifera*.) Is largely used in some parts of India as an application to indolent ulcers and wounds and is supposed to form the chief ingredient of "Wroughton's ointment." It has the odour, taste and consistence of a balsam.

(7052) *Theetsee*. (*Melanorrhœa usitata*). The celebrated *theetsee* dammer was exhibited by Dr. Brandis from Pegu and Capt. Benson from Moulmein. The latter exhibitor also forwarded a half log of the tree which is probably the first ever imported into Madras.

(7053) *Gamboge*.

(7054) *Xanthoxylon triphyllum*. A very small quantity of the resin obtained from this tree was exhibited by the Rev. Mr. Johnson of Cottyam. Judging from the specimen it appears to be produced in too small quantities to be useful in a commercial point of view, but the jury awarded honorable mention for the carefulness of the exhibitor in identifying the plant and supplying the correct botanical name of this new product.

(7055) *Googool*. This gum resin, is chiefly used as a medicine.

(7056) *Gum Elastis*.

(7057) *Moringa gum* much resembles tragacanth, although its partial elasticity has caused it to be classed amongst the elastics. No use is known for this abundant product.

(7058) *Gums properly so called*.

(7059) *Acacia gum*.

(7060) *Egle marmelos*.

(7061) *Cashew tree gum*.—(*Anacardium occidentale*).

(7062) *Azadirachta Indica*.

(7063) *Kuteera*.—The produce of the *Gossypium lospermum gossypium* much resembles tragacanth

(7064) *Wood apple gum*.—(*Feronia elephantum*.) This is one of the best gums included under the general name of *gum arabic*.—*Lieut Hawkes, Reporter on Sec. I, Class IV : M. E. of 1857*

(7065) RHAMNACEÆ, a natural order of Exogenous Plants, remarkable for having a valvate calyx, hooded petals, opposite to which their stamens are inserted into the tube of the calyx and a superior or half inferior fruit which is either dry or fleshy. The species are found nearly all over the world, except in the arctic zone. The chief number of species is said to be dispersed through the hottest parts of the United States, south of Europe, north of Africa, Cape of Good Hope, and Australia. They are all shrubs, with small greenish or inconspicuous flowers.

The species which are best known in Great Britain are the *Rhamnus frangula*, Alder ; *R. catharticus*, Buckthorn ; *Paliurus Australis*, Christ's Thorn ; and Buckthorn ; the evergreen *Rhamnus Alaternus*. The useful species are of some importance :—*R. catharticus* and several others have purgative berries ; *R. infectorius* yields the French berries of the shops employed for dyeing yellow ; the fruit of the Jujube, *Zizyphus Jujube* and *Z. vulgaris*, is sub-acid and eatable, and the species are cultivated for it in the south of Europe and the temperate parts of Asia ; *Z. Lotus* gave its name to the Lotophagi, or Lote-Eaters, of Africa ; and *Rhamnus frangula* is extensively cultivated for the manufacture of charcoal. *Ceanothus Americanus* yields the New Jersey Tea. [Ceanothus ; Hovinia ; Paliurus ; Rhamnus.]—*Eng. Cyc.*

(7066) RHAMNUS (the word is Greek, ῥάμνος), a widely diffused genus of Plants, the type of the natural family *Rhamnaceæ*. It is chiefly found in the temperate parts of Europe, in Siberia, and in the Himalayas at elevations of 6,500 feet; also in the New World, and at the Cape of Good Hope.

The genus is characterised by having an urceolate 4-5-cleft calyx; petals wanting, or emarginate; anthers ovate, 2-celled; disc thin, overspreading the tube of the calyx; ovary superior, 3-4-celled; styles 3 or 4, distinct or united; fruit fleshy, with 3 or 4, or in consequence of abortion, 2 fibrous indehiscent stones.—*Eng. Cyc.* The juice of the unripe fruit of *Rhamnus infectorius, catharticus* and *virgatus*, known as Turkey or French berries, is used for dyeing leather yellow. When mixed with lime and evaporated to dryness, it forms the color called sap-green. A great quantity of yellow berries are annually shipped from Constantinople: 115 tons were imported into Liverpool in 1853. The average annual imports into the United Kingdom are about 450 tons. They come from the Levant in hair bales weighing three and a quarter cwt., or in tierces of four to five cwt., and are used by calico printers for dyeing a yellow color. They are sometimes called Persian berries. It is a subject of surprise that the common betel-nut of the East has never been introduced for dyeing purposes.—*Simmonds.* Dr. Wight, in Icones, gives Rhamnus hirsutus, 978; Wightii, 159; *Zeylanica*, 1899.

(7067) RHAMNUS: *Species.* The GREEN DYE RHAMNUS. While upon the subject of Chinese dyes, says Fortune, I shall now give some account of the "green indigo," which has been attracting much notice lately both in India and in Europe. A portion of cotton cloth obtained in China by the French manufacturers being greatly admired on account of the peculiar green of its dye, was submitted to the celebrated chemist, M. Persoz, with a request that he would endeavour to ascertain the composition of the green colour. The following is a translation of his report upon this subject to the Academy of Sciences:—Every attempt that I made upon the specimen to detect evidence of the presence of a blue or yellow failed, and I was led to the conviction, by isolating the coloring principle, that the green was produced by a dyeing material of a peculiar nature and sui generis. It further was evident,

1st.—That the coloring matter was an organic product of vegetable origin.

2nd.—That the fabric on which it was fixed was charged with a strong dose of alum and a little oxide of iron and lime, bodies the presence of which necessarily implied that mordants had been used in dyeing the calico.

These results were so positive, and at the same time so opposed not only to everything known in Europe regarding the composition of green colour, but also to all that is recorded by writers regarding the dyeing processes employed in China for the production of green, that I was induced to go into a more detailed investigation of the subject; and about the end of last November I applied to Mr. Forbes, the American Consul at Canton, for some of this valuable material. I am indebted to his kindness for a specimen weighing about one gramme (15½ grains). The substance is met with in thin plates of a blue colour, having a strong analogy with that of Java indigo, but of a finer cake and differing besides from indigo both in its composition and in all its chemical properties. On infusing a small fragment of the substance in water, the liquid speedily became coloured of a deep blue with a shade of green. After the temperature had been raised to the boiling point, a piece of calico, prepared for printing with mordants of alum and oxide of iron, was dipped in it and a true dye was the result. The following appearances were observed. The portion of the fabric to which alum had been applied showed a deep green, of more or less intensity, according to the strength of the mordant. The portions charged with both alum and oxide of iron yielded a deep green, with a shade of olive. The portions charged with oxide of iron alone yielded a deep olive. The parts of the cloth where no mordant had been applied remained sensibly paler. The colours thus obtained were treated with all the re agents to which the Chinese calico had in the first instance been subjected, and they behaved in precisely the same manner. From these experiments it may be inferred,

1st. That the Chinese possess a dye-stuff presenting the physical aspect of indigo, which dyes green with mordants of alum and iron.

2nd. That this dye stuff contains neither indigo nor any thing derived from that dyeing principle. Mons. Legentil, President of the Chamber of Commerce of Paris, having perceived the importance of France being speedily put in possession of this valuable material, with a view to the interests of science and of industry, took the necessary steps several months ago for procuring a suitable quantity with the least possible delay, and at the same time to have inquiries made as to its origin and mode of preparation.

Mr. Fortune here adds, that the investigation of the green dye-plant exhibits as many amusing blunders as used to be made about the Chinese sicepaper plant in former days. By some, the flowers of the Whi-mei (Sophora japonica) were sent home as the "green indigo," but this plant yields a yellow dye and even when mixed with blue to make a green, the green is not that kind noticed by the French manufacturers. At another place he says, here I found fields under cultivation with a kind of Rhamnus apparently. The Chinese farmer called it "Loh-zah, or "Soh-loh-shoeo"

and showed me samples of the cloth which had been dyed with it. To my delight these samples corresponded exactly with those sent back from France, one of which was in my possession, but he told me that two kinds were necessary—namely the variety they cultivated in their fields and one which grew wild on the hills—in order to produce the dye in question. The former they called the yellow kind and the latter the white kind. The dye itself was not extracted by them they were merely the growers and therefore I could get no information as to its manufacture. I however secured a good supply of plants and seeds of both kinds, which were afterwards sent to India and England. My further inquiries on the subject of the manufacture of the "green indigo" were conducted in connexion with Dr. Lockhart and the Rev. J. Edkins, of Shanghae. We found that a considerable portion of this dye was made near a city called Kia-hing-foo, situated a few miles west from Shanghae and Mr. Edkins procured a bundle of chips there which exhibited the state in which the article is sold in the market. Since I left China I have received the following interesting letter from Dr. Lockhart, which throws much light on the subject. The information was procured by Mr. Edkins and may therefore be fully relied upon. "The bark of two kinds of the tree known as the 'green shrub' (Luk-char), one wild which is called the white and another cultivated, which is called the yellow, are used to obtain the dye. The white bark tree grows abundantly in the neighbourhoods of Kea-hing and Ningpo; the yellow is produced at Tsah-kou-pang, where the dye is manufactured. This place is two or three miles west from Wang-steen, a market-town situated a little to the south of Kea-hing. "The two kinds are placed together in iron pans and thoroughly boiled. The residuum is left undisturbed for three days, after which it is placed in larger eartheruware vessels, and cotton cloth, prepared with lime, is dyed with it several times. After five or six immersions the colouring matter is washed from the cloth with water, and placed in iron pans to be again boiled. It is then taken upon cotton yarn several times in succession and when absorbed in this way it is next washed off and sprinkled on thin paper. When half dry the paper is pasted on light screens and strongly exposed to the sun. The product is called Luk-kaou. In dyeing cotton cloth with it ten parts are mixed with three parts of subcarbonate of potash in boiling water. "The dye made at Tsah-kou-pang is not used to dye silk fabrics, because it is only a rough surface which takes it readily. To colour silk with it so much of the material must be used that it will not pay. All cotton fabrics, also grass cloths, take the colour readily. The dye does not fade with washing, which gives it a superiority over other greens. "It is sent from Kea-hing as far as Shan-ting. It is also made in the province of Hoonan and at Ningpo, but the dye at these places is said to be of an inferior quality. It has long been used by painters in water-colours, but the application of it to dye cloth was first made only about twenty years ago. If some method could be discovered of applying it to silk fabrics it would become still more useful." The information obtained by Mr. Edkins on this subject is, no doubt, perfectly correct. It agrees in the most important particulars with what I had gleaned from time to time amongst the Chinese in various parts of the country. The chips he brought with him from Kea-hing were identical with the "Soh-loh," or "Loh-zah" (Rhamnus sp.) which I have already mentioned, and his statement that two varieties of the plant are used to produce the dye agrees with my own observations. The mode of extracting the dye from the bark or wood (for both seem to be used), as practised by the Chinese, appears to be slow and tedious, but with our superior knowledge of chemistry this might possibly be improved. From these investigations it would appear that two colouring principles are necessary to the production of this dye. This however, will not affect the value of it as a rich and permanent green, a quality which has been appreciated by the French manufacturers, and which is also well known to the Chinese.—*Fortune's Res. among the Chinese*, p. 167. At another place he mentions that the *Rhamnus* producing the green indigo (so called) has been discovered and introduced both to England and to India,—*Fortune's Res. among the Chi. page* 146. The probability of this discovery proving correct, is supported by the fact that it is from one of this genus, the *Rhamnus catharticus* of Europe that the pigment called Sap green or Bladder-green is obtained. Voigt gives *Rhamnus* incanus and R. Virgatus.

(7068) RHAMNUS CATHARTICUS (called also *Spina cervina*, hence Buckthorn), indigenous shrub, with opposite branches, spreading, straight, round, smooth, hard, and rigid, each terminating in a strong spine after the first year. Leaves deciduous, bright green, smooth, ribbed, the young ones downy. Flowers yellowish green, on the last year's branches numerous; the fertile ones with narrow petals, rudiments of stamens, and a deeply 4-cleft style; barren ones with an abortive ovary, and broader petals. It flowers in May, ripening its berries in September, at which time they are collected. The berries are about the size of a peppercorn, black externally, but within of a deep violet, the pulp inclosing three or four seeds. The taste is nauseous and repulsive at last, though at first sweetish and only bitter. They contain a peculiar extractive, a colouring principle, acetic acid, and gum. The fresh and dried berries, the expressed juice,

ır a syrup prepared from them, all possess pur-
ative properties, exemplified in that form which
as led to the designation 'hydragogue.' Its action
s attended with much sickness, griping and
hirst. It should be restricted to the arts, in
hich it is serviceable, being the source of the
igment called Sap-Green or Bladder Green.
—*Eng. Cyc.*

(7069) RHAMNUS FRANGULA, Alder
Buckthorn, has alternate branches and elliptical.
t is a native of the British Islands.—*Eng. Cyc.*

(7070) RHATANY ROOT. Is derived from
ıe *Krameria triandra*, and consists of cylindri-
al ramifications, varying in size from that of
quill to a finger. It is obtained from Peru,
nd is used as an astringent medicine.—*Water-
on.—Faulkner.*

(7071) RHEUM, a genus of Plants belong-
ıg to the natural order *Polygonaceæ*, of which
ıe name is taken from the Ῥέον of Dioscori-
es, and which includes the different species of
lants which yield the stalks and root so well
nown by the name of Rhubarb. It is doubted
y some whether the root to which the name
rha' and 'rheon' was applied by the Greeks
as the same as that to which we now apply the
ıme of rhubarb, because the descriptions of the
ırmer given by Dioscorides and Pliny do not
ply to the latter. It is admitted however that
ır rhubarb was known to the later Greek phy-
cians, as Alexander of Tralles and Paulus of
Egina, and there is no doubt that the Arabs were
ell acquainted with it; and it is remarkable
ıat they quote 'rheon' as the Greek synonyme
their 'rawund,' which is rhubarb, and which
ıey describe as being of various kinds, as In-
an, Turkish, Chinese, and from Khorassan.
rom this it is probable that one kind may have
ecome substituted for another as the communi-
tion with the east increased. Long as the
hubarb root has been known, it is remarkable
at the species of *Rheum* yielding it is yet un-
ıown; this is in consequence of the best rhu-
ırb, Turkey rhubarb, being only obtained by
e Russians at Kiachta from the Chinese. That
lled Chinese may be the produce of the same,
of a different species, from the northern
ındaries of that country. Dr Royle, after
viewing the different accounts of the commerce
rhubarb, states:—"This would bring the
ubarb, country, within 95° of E. long. in 35
N. lat., that is, into the heart of Tibet.
s no naturalist has visited this part, and
ither seeds nor plants have been obtained
ence, it is as yet unknown what species yields
is rhubarb plant." Sievers had previously
ld that his travels had satisfied him that as yet
body, that is, no scientific person, has seen
e true rhubarb plant. The Himalayan and
ersian rhubarbs have alone been ascertained.
ıe different species of rhubarb are important
ınts, not only on account of the roots being
so extensively employed, and so valuable for their medicinal qualities, but also on account of the stalks of the leaves being now so much employed, from their agreeable acidity, in making tarts, &c. As the species are all indigenous in cold parts of the world, that is, from the southern parts of Russia, Siberia, Tibet, the north of China, and the Himalayas, so they may all be grown in the open air of Great Britain and several are cultivated on account of their stalks. Some also, both in England and France, are cultivated on account of their roots, often for the purpose of adulteration. The genus *Rheum* is characterised by having an inferior petaloid sexpartite calyx, into the bottom of which the stamens, about nine in number, are inserted; anthe s opening lengthwise; ovary superior, with a single erect ovule; styles 3, reflexed; stigmas peltate, entire; fruit (achenium) 3-cornered, winged, with the withered calyx at the base. The species which are known and cultivated are the following: (Royle, *Illustr. Himal. Bot.*; Lindley, *Flora Medica*; Pereira, *Elements of Materia Medica*) *Eng. Cyc.*

(7072) RHEUM, CASPICUM, Fischer (*R. rhaponticum*, Ledbour); in the Altai Mountains. Leaves ovate, acuminate, obtuse, cordate, inflexed at the base, thick, very wavy, glossy on the upper but slightly downy on the under side. Petiole pale green, minutely downy.—*Eng. Cyc.*

(7073) RHEUM COMPACTUM, Linn.; Tartary and China. Leaves heart-shaped, obtuse, very wavy, deep green, thick, quite smooth on both sides, glossy on the upper. Sinus nearly closed with parenchyma. Petiole green.—*Eng. Cyc.*

(7074) RHEUM CRASSIVERNIUM, Fischer. Leaves heart-shaped, acuminate, obtuse, wavy, bullate, deep-green, quite smooth, rather glossy above; ribs slightly coloured red, the centre ones above half an inch deep at the base. Petiole dull red, rounded, rather angular.—*Eng. Cyc.*

(7075) RHEUM EMODI, Wallich, *R. australe* of Don, is found in Kumaon. The root is a valuable medicine, though bearing hardly any resemblance to that of the shops. Stems much branched, six to ten feet high, very thick below, gradually diminishing, and spreading into large panicles, and these rough, with minute warts. Leaves very large, cordate, acute, dull-green, but little wavy, very rough, covered with little hairs. Petioles very rough, furrowed, and very much narrower at the upper than the lower end. Panicles terminal, very long. Flowers blood-red, very small.—*Eng. Cyc.* Honigberger mentions that *Rheum Australe* Don, *Rheum Emodi* Wall, vegetates in wild luxuriance on the Cashmerian mountains. It is considered as one of the best rhubarbs; notwithstanding the coarse appearance of its exterior.

The best of all is, it can be had fresh and cheap in any quantity, and at any time Besides, it must necessarily have its own peculiar properties, such as are not to be found in any other sort of rhubarb.—*Thirty-five years in the East, by Dr. Honigberger, p.* 335.

(7076) RHEUM LEUCORHIZUM, Pall (*R. nanum*, Sievers; *R. tataricum*, Linn.). A small plant though said to be equally efficacious with the best sorts. Radicle leaves about three, short stalked, from four to six inches long, and from five to nine inches broad; smooth on both sides, tooth-letted at the edge. Flowering stem about two inches high when in flower, afterwards becoming ten to twelve inches high.—*Eng. Cyc.*

(7077) RHEUM MOORCROFTIANUM, (Royle), Small-Stalked Rhubarb, leaves and stems covered with short pubescence; petioles deeply furrowed; the stipules as long as the petioles and very membranous; scales at the base yet longer, extremely thin, and towards the summits much torn. This species was found by Messrs. Moorcroft and Hearsay near the Niti Pass in the Himalayas, at an elevation of 12,000 feet.—*Eng. Cyc.*

(7078) RHEUM PALMATUM, Linn., generally thought to be the source of the true officinal rhubarb; near the great wall of China. Leaves roundish, cordate, half palmate; the lobes pinnatifid, acuminate, deep dullgreen, not wavy, but uneven and very much wrinkled on the upper side, hardly scabrous at the edge, downy on the under side. The flowering stems are taller than those of any other species.—*Eng. Cyc.*

(7079) RHEUM RHAPONTICUM, Linn; north of the Caspian. According to Guibour, cultivated largely near Lorient, in the department of Morbihan in France, at a place called from that circumstance Rheumpole. Leaves roundish, ovate, cordate, obtuse, but little wavy, very concave, even, very slightly downy on the under side. Panicles very compact and short, always rounded at the ends, and never lax. *R. rhaponticum*, *R. hybridum*, R. *compactum*, and hybrid varieties of them, are the common garden rhubarbs.—*Eng. Cyc.*

(7080) RHEUM RIBES seems to be so named from the Persian name Ribas, which is as frequently written Rewash, and which Elphinstone, Burnes, and other travellers notice as being highly esteemed by the Persians, and of which the stalks are prepared in a variety of ways, and considered a great delicacy.—*Eng. Cyc.*

(7081) RHEUM SPICIFORME, Royle, 'Illust.,' t 78, found on the northern face of the Himalayas. Leaves thick, leathery, cordate, blunt, red and netted beneath, and covered with stellate down on each side. Pedicels numerous, clustered, as long as the ripe fruit. The roots are lighter coloured and more compact than those of *R. Emodi.*—*Eng. Cyc.*

(7082) RHEUM UNDULATUM, Linn. (*R. rhubarbarum*, Linn.), China and Siberia. Leaves oval, obtuse, deep green, with veins purple at the base, often shorter than the petiole, downy on each side when young, looking as if frosted. Petiole downy, blood-red, semi-cylindrical.—*Eng. Cyc.*

(7083) RHEXIA VIRGINICA. *Melastomaceæ*. This is a genus of shrubby plants, handsome when in flower, they require a good soil, and may be propagated by seed or dividing the roots, colours are purple, pink and white.—*Riddell.*

(7084) RHEUM WEBBIANUM, Royle, 'Illust.,' t. 99.; *R. Emodi* of Meisner, found by Mr. Moorcroft at the height of 12,000 feet above the level of the sea, and by Dr. Royle on the Choor Mountain. Root leaves large, long-stalked, rather downy above, veiny beneath, margin hairy. Axillary racemes clustered, terminal, panicled; pedicels in threes, twice as short as the ripe fruit.—*Eng. Cyc.*

(7085) RHINACANTHUS (from ῥίν, a snout, and ἀκάνθα, a thorn), a genus of Plants belonging to the natural order *Acanthaceæ*. It has a regularly 5-parted calyx with small subulate bracts and bractlets; a hypocrateriform 2 lipped corolla, with a long slender tube, the upper lip narrow, the lower trifid, with equal segments; 2 stamens inserted in the throat of the corolla, the anthers 2-celled, awnless, with one cell placed above the others almost in a line; a clavate capsule much compressed at the base, with the commissure of the valves in contact and seedless; the upper part 4-seeded, or by abortion 2-seeded; the dissepiment complete, adnate; the seed ovate, bi-convex, augmented with hooks which are concave and obtuse.—*Eng. Cyc.*

(7086) RHINACANTHUS COMMUNIS. *Syn.* JUSTICIA NASUTA, WHITE-FLOWERING JUSTICIA. Linn. *Roxb. Flora Indica*, i. p. 120. *Rheede*, ix. t. 69.

Pulcolli, RHEEDE.	Naga mulli, TEL. and TAM.
Kabooter ke jur HIND.	
Jooi panee, BENG.	*O'Shaughnessy, p.* 8.

Rhinacanthus Communis, is a native of the continent of India, with opposite stalked broad-lanceolate obtuse leaves, above smooth, below a little downy, entire, from two to four inches long and from one to two inches broad, and a fleshy ring surrounding the base of the ovary. The roots of this plant are boiled in milk, and are reckoned by the natives of India as aphrodisiac. In conjunction with lime-juice and pepper they are used as an external application for ringworm. (Lindley, *Flora Medica.*)—*Eng. Cyc.* It is used also for the bites of venomous snakes, hence the Telinga and Tamul name Naga mulli, or jasmine of the cobra capella. "Naga," as

Roxburgh informs us, is prefixed to most of the native antidotes, and occurs very often in their writings,—" like the ancient physicians of Greece and Rome those of India at this day make poisons and their antidotes a very chief part of their studies, but from the seeming inactivity of a very large share of them, we may safely conclude that their practice is equally frivolous with that of the ancients, and ought to be discouraged as much as possible, because at least they prevent the application of more efficacious remedies."—*O'Shaughnessy, page* 481. R. Communis grows spreading along the ground (*Riddell*); and is found in the native gardens as a flower. The flowers are sold along with those of Jasmine and the root used in medicine as an excitant.—*Gen. Med. Top. p.* 173.

(7087) RHINOCEROS (the Greek Ρινοκέρως), the name of a genus of Pachydermatous Quadrupeds, placed by Linnæus in his order *Bruta*; and by Illiger in his order *Mullungla*, family *Nasicornia*. It has been a question whether one of the species, *Rhinoceros unicoris*, Linn. (R. *Indicus*, Cuv. and Desm) is not the ראם (Reem), or רים (Rem), of Scripture (Numb. xxiii. 22; xxiv. 8; Deut., xxxiii. 17; xxxix. 9 10; Psalms, xxii. 21; xxix 6; xcii 10; Isaiah xxxiv. 7). In the Septuagint the word is translated Μονοκέρως, or Unicorn, except in Isaiah, where it is rendered ' Αδροὶ (or the mighty or powerful ones). In the Trigurine and Vulgate versions the word is rendered (Numb., xxiii 22; Job xxxix. 9, 15) Rhinoceros, with a note to the former, that others read Monoceros; and in Scheuchzer's ' Physica Sacra' we have (Tab. 313) Numb., xxiii. 22. illustrated by a somewhat extravagant and exaggerated figure of a one horned Rhinocerous, with " Reem: Rhinoceros" below the plate. In the Bible " Imprinted at London by Robert Barker, Printer to the King's most excellent Majestie" (' Breeches Bible), the word used is ' Unicorn;' and ' Unicorn' is the expression in the version now in use in our churches. Some are of opinion that the Reem, or Reim, of Scripture were savage animals of the Bovine genus, and others that the word signified the Oryx, observing that Reem is the Arabian name for a species of wild-goat or gazelle. These allege that the Reem was two-horned. (Deut. xxxiii. 17; Psalms, xxii 21.) The better opinion seems to be that the animal or animals intended to be designated in most of the passages quoted, if not in all, was or were the *Rhinoceros unicornis*, or Great Asiatic one-horned Rhinoceros. M. Lesson expresses a decided opinion to this effect; and indeed the description in Job (chap. xxxix) would almost forbid the conclusion that any animal was in the writer's mind except one of surpassing bulk and indomitable strength. It has also been doubted whether accounts of the Indian Ονος ἄγριοι (Wild Asses) given by Ctesias (' Indic.,' ed Bahr) were not highly coloured and exaggerated descriptions of animals of this genus, and whether the Ονος Ινδικός (Indian Ass) of Aristotle was not a Rhinoceros.

The osteology of the various species of *Rhinoceros* differs very considerably. The following differences appear on examining the skull of the two-horned species of the Cape:—1. On its upper surface the horizontal contour of the bones of the nose is rounded in the Cape species, and almost extravagantly so in *R. simus*, whilst in the one horned species it is pointed. 2. The principal differences in the profile relate to the form of the incisive bones, which in *R. Indicus* advance as far as the bones of the nose, and have above a particular apophysis: in *R. Africanus* and *R. simus* the incisive bones are each reduced to a small oblong piece. 3. On the lower surface, besides the differences which result from the form of the zygomatic arches, the direction of the occipital crest, and that which the difference of the incisive bones produces on the front of the palate, it may be observed that the series of molars is longer in *R. Africanus* and *R. simus*, and that it converges anteriorly with that of the opposite side. 4. The posterior surface is demi-elliptical, and higher than it is wide in *R. Indicus*, and rather wider than it is high in *R. Africanus* and *R. simus*, in which last the occipital foramen is wider than it is high, whilst in *R. Indicus* those proportions are reversed. The principal differences of the lower jaws are (besides the length which precedes the molars, which is much less in *R. Africanus* and *R. simus* than in *R. Indicus*), 1st, that the series of molars is longer in the African species; 2nd, that the rising branches are much less high; 3rd, that the coronoid apophyses are much shorter, less pointed, and less directed forwards; 4th, that the dental branches are much more convex externally. The One-Horned Rhinoceros of Java (*R. Javanus*) resembles less, in the bones of the extremities, the *R. Indicus*, than does the *R. Africanus*; which, as Cuvier observes, is remarkable. But in the skull the resemblance to that of *R. Indicus* is striking, though there are still remarkable differences. The whole cranium, for instance, is less, and the zygomatic arches, the orbits, and the nasal bones, which terminate in a sharp point, are less developed. We now proceed to give some account of the species of *Rhinoceros*:—*Eng. Cyc.*

(7088) RHINOCEROS AFRICANUS. Cuv. (*R. bicornis*, Linn.), is of a pale yellow brown; horns unequal in length; neck surrounded with a furrow at the setting on of the head; eyes brown. Length 10 feet 11 inches. (Smith.) The hide is pale yellowish-brown, with tints of purple upon the sides of the head and muzzle; the groins flesh-coloured; eyes dark brown; the horns livid-brown clouded with green; the hairs on the tip of the tail and the margins of the ears deep black.—*Eng. Cyc.*

(7089) RHINOCEROS INDICUS (*R. unicornis*, Linn.) has a single horn on the nose. Skin naked, very thick, of a dull deep purplish-gray, marked with sub-elevated, rounded, and other inequalities, and remarkable for the deep folds which it forms behind and across the shoulders, and before and across the thighs, &c. There are a few stout, stiff, horny, and smooth hairs on the tail and on the ears. The species inhabits the East Indies, especially beyond the Ganges. It is recorded as having been found in Bengal, Siam, and Cochin-China. Shady forests, the neighbourhood of rivers, and marshy places are favourite localities. Their ordinary food consists of herbage and the branches of trees. The flesh is said to be not unpalatable. —*Eng. Cyc.*

(7090) RHINOCEROS JAVANUS (Cuvier) has one horn; folds of neck obsolete; scutules of the skin angled at the margin, concave in the middle, and furnished with a few short bristles; margin of the ears and under side of the tail hairy. The marks of distinction afforded by the folds of the external covering were less evident than those afforded by the form of the body and the attenuated head; but the folds on the whole appeared less rough or prominent than in *R. Indicus*. This animal is gregarious in many parts. Dr. Horsfield states that it is not limited to a particular region or climate but that its range extends from the level of the ocean to the summit of mountains of considerable elevation. Dr. Horsfield noticed it at Tangung, near the confines of the Southern Ocean, in the districts of the native princes, and on the summit of the high peaks of the Priangan regencies. It prefers high situations. This species is the Warak of the Javanese, the Badak of the Malays and of the inhabitants of the western parts of Java. (Horsfield, 'Zoological Researches in Java.')—*Eng. Cyc.*

(7091) RHINOCEROS KEITLOA (Smith) is of a pale brownish-yellow colour; the two horns subequal in length, the anterior one cylindrical, the posterior one compressed; anterior part of the upper lip produced and acuminate. Dr. Smith remarks that the only species yet known with which the present could be confounded is the *R. bicornis* of authors There are however, he observes, many and marked differences between them, of which the following are a few of the external and more palpable ones. In *R. Keitloa* the two horns are of equal or nearly equal length; in *R. Africanus* the posterior in neither sex is ever much beyond a third of the length of the anterior horn; the length of the head in proportion to the depth is very different in the two.

(7092) RHINOCEROS SUMATRENSIS, Cuv. (*R. Sumatranus*, Raffles), has four great incisors, as in the two preceding species, but hardly any fold on the skin, which is hairy; a second horn behind the ordinary one. The first satisfactory indication of the existence of this species occurs in Pennant, who imagined that the two-horned species of Sumatra was identical with *R. bicornis*, the only African species then known. He quotes the following remark of Mr. Charles Miller, who was long resident in Sumatra:—"I never saw but two of the two-horned Rhinoceros; but I believe they are not uncommon in the island, but are very shy, which is the reason they are but seldom seen. I was once within twenty yards of one. It had not any appearance of folds of plaits on the skin; and had a similar horn resembling the greater, and, like that, a little turned inward. The figure given by Dr. Sparrman is a faithful resemblance of that I saw

The hide is rugose, covered with scattered stiff brown hairs; folds on the shoulders and croup but slightly marked; the skin generally rather delicate, and nearly without folds; head rather elongated; eyes small and brown; upper lip pointed and curved downwards; ears small and pointed, fringed with black short hairs; first horn bent backwards, second smooth and pyramidal, placed a little in front of the eyes. It is a native of Sumatra.—*Eng. Cyc.*

(7093) RHINOCEROSES FOSSIL. The Fossil Rhinoceroses hitherto discovered may be divided into three groups—3, those with a true or bony septum narium; 2, those without a bony septum; and 4, those with incisor teeth. The greater portion of remains found in Northern and Central Europe and Asia belong to the first group; those found in Italy belong to the second. The skulls of the Rhinoceroses belonging to the first group exhibit an essential difference when compared with those of the living species. Those of the former are longer and narrower in proportion; the width between the orbits is less; the bones of the nose are more elongated; the disc on which the anterior horn was seated is an oblong ellipse, whilst in *R. bicornis* it is a hemisphere. An analogous elongation exists in the place where the second horn was situated, whence Cuvier concludes that the horns of the Rhinoceros with a bony septum narium were very much compressed laterally. The same great zoologist remarks that in *R. bicornis* or *R. Africanus* (Cape Rhinoceros) the occipital crest is nearly over the occipital condyles, and the posterior surface of the occiput is nearly perpendicular to the axis of the head. In *R. Javanus* this surface is inclined forwards, which renders the distance from the nose to the crest shorter than that from the nose to the condyle in a proportion of 19 to 25.—*Eng. Cyc.*

(7094) RHIZOPHORACEÆ, *Mangroves*, a natural order of Exogenous Plants, natives of the shores of the tropics, where they grow in the mud, and form a close thicket down to the verge of the ocean. They are trees or shrubs, with simple

opposite leaves, having deciduous interpetiolary stipules. The calyx is adherent, with 4-12 valvate lobes ; petals 4-12 : stamens twice or thrice as many ; ovary 2-4-celled, with two pendulous ovules in each cell. The fruit is monospermal, indehiscent, crowned by the calyx. Seed exalbuminous, embryo germinating in the pericarp. There are 21 species and 5 genera. The bark of the trees is usually astringent, and is employed in tanning and as a febrifuge. The wood of several is described as being hard and durable.—*Eng. Cyc.*

In the West Indies, cordage is made of the bark of a species of Mangrove, which is hence called Rope Mangrove. The coasts of the Bay of Bengal and of the Indian islands abound in the Mangrove, which is found also at the mouths of the Indus. Its bark has been used for tanning purposes, for which it is probably more suitable than for cordage.—*Royle. Ill. Pl. p.* 301. The bark of a small Mangrove tree *Kandelia Rheedii* from the mangrove swamps is used by the Tavoy women in dying red, but Mason thinks as a mordant.—*Mason* The following species of *Rhizophora* are the best known forms of the order :—

(7095) RHIZOPHORA GYMNORHIZA. Rheede.

Kayu-api-api, Malay.

Handeb kakora of the Delta of the Ganges. *Rhizophora gymnorhiza* grows to a considerable size where the spring-tides rise over it, as in the delta of the Ganges. The wood is yellow, hard, and durable ; has a sulphurous smell, and burns with a vivid light ; is chiefly used by the natives for fire-wood and making posts for constructing their houses. The pith of the wood, boiled in palm wine or with fish, is used as food.—*Eng. Cyc.* Trunk generally dividing before it reaches the ground like a parcel of hop poles piled up in form of a cone ; the seeds hang down : from the apex proceeds the root : attains a considerable magnitude in places over which the spring tides rise. The wood is of a yellowish colour, hard and durable ; its chief use is for burning and for posts with which to construct the houses of the natives.—*Rohde M. S. S.* It is used for fuel in the Archipilago.—*Crawfurd.*

(7096) RHIZOPHORA MANGLI. Common Black Mangrove, Rheed.

Pukandel, Tel. Tam.	Manggi,-Manggi, Malay.
Oopoopoma, Beng.	Bhora, Beng.

Rhizophora Mangle, Bhora of the Delta of the Ganges, the common or Black Mangrove, is found abundant on the shores of the ocean, and within the delta of the Ganges, where it grows to a considerable size. The seed of this species, which is from one to two feet long, very quickly gives rise to a young tree, and, as mentioned by Browne in his 'History of Jamaica,' if the apex from whence the root issues be stuck only a little way in the mud, the leaves quickly unfold at the opposite end. The wood is dark-red, hard, and durable, and the bark is used for tanning leather.—*Eng. Cyc.* This tree forms a striking feature in the physical geography of the archipelago as it does indeed of all tropical countries, for a belt of it as deep as the reach of the tide is always found wherever there is a shallow and muddy shore. The tree which rises to the height of forty or fifty feet is invariably found in such situations constituting a dense, and almost impenetrable forest. Each tree stands in a cradle of its own roots from five to six feet high, bare at low water but at high water covered so as to give the appearance of trees growing in the sea. The mangrove jungle is the favorite resort of musquitos and crocodiles, and affords a convenient and almost inacessble retreat to the pirate.—*Crawfurd, p.*266. The Mangrove Bark of *Rhizophora mangle*, is used to dye chocolate color in the East and West Indies. This was one of the colors introduced by Dr. Bancroft, and for the exclusive use of which he obtained an Act of Parliament. It is procured in plenty at Arracan, Malabar and Singapore in the East (*Simmonds*). Also, in the Indian Archipelago, it is used in tanning : its wood gives a red dye.—*Crawfurd, page* 266. The great length of the seed of this species gives in a very short time a young tree, for if the apex from which the root issues is only stuck a little way into wet soil or mud the leaves quickly unfold at the opposite end The wood is of a dark reddish colour, hard and durable. This species is valuable from its property of growing in salt marshes subject to the influence of the tide.—*Rohde, M.S.S.*

(7097) RHIZOPHORA MUCRONATA, is a species given by Dr. Wight.

(7098) RHODANTHE. Compositæ. This plant is a native of the Swan River, and is said to be as beautiful an annual as has been introduced into the English collections. It grows to a large size, and is covered with innumerable blossoms of rose and yellow colour ; when grown from seed, the plants require to be continually shifted into larger pots, and the blossom buds at first pinched off ; the shifting may be repeated five or six times until the plants have acquired a shrubby character, when the flowers will all expand, and continue in succession for some time.—*Riddell.*

(7099) RHODODENDRON, a genus of Plants belonging to the natural order *Ericaceæ*. The species are evergreen shrubs, very commonly cultivated in English gardens and shrubberies, and differing from *Azalea* principally in the stamens, being 10 instead of 5, in the corolla being campanulate, not tubular, and in the foliage being hard and evergreen. The species are nearly related to each other, and occur both in the New and Old Worlds. Thirty-two species of the genus *Rhododendron* have been distinguished by De Candolle in the seventh volume of his 'Prodromus,' in 1839 ; the maximum of known

species at the present time exists in Asia; for, commencing with Borneo and other Malayan islands in the tropics of the southern hemisphere, and proceeding north, we find them recorded in the mountain regions of all intervening countries that have been botanically investigated, even to northern and extreme arctic Siberia. As we proceed westward into Europe they gradually disappear, one only inhabiting Sweden and Norway, *R. lapponicum*, and that seems not to extend to the western coasts. No species grows in Mexico or near the coasts of Oregon or California, and none in the isthmus of Panama. Throughout the whole of Africa and Australia the genus is unknown, and it will be observed that it only enters the southern hemisphere through the medium of the Indian Archipelago. Mr. Griffith in an excursion to one mountain in Bootan detected eight species, and Dr. Hooker, during a very limited sojourn in Sikkim, and notwithstanding great difficulties, was able to collect and describe a far larger number. These facts would lead to the conclusion that if the maximum of Rhododendrons be in Asia, their head quarters are on the lofty ranges of the Eastern Himalayas, where the mild and moist atmosphere is eminently suited to their habits. (Lindley, *Vegetable Kingdom*; Dr. Hooker, *Rhododendrons of the Sikkim Himalaya*.) Within the last few years a number of species of these beautiful plants has been found in the Himalayan Mountains by Dr. Joseph Hooker, who has described them in his 'Monograph of the Rhododendrons of the Sikkim Himalaya.' The most beautiful of these forms are the R. Falconeri; Dalhousiæ; R. Barbatum R. Lancifolium; R. Wallichii, and R. Argentum.—*Eng. Cyc.* Dr. Wight gives in his Icones, Rhododendron arboreum, 1018-1201, formosum, 1202, grande, 1202, and Griffithianum, 1203. Numerous varieties are to be procured in Britain, those of *R. ponticum*, *R. maximum*, and *R catawbiense* are the most robust; *R. hybridum* obtained between the Indian and American species is less hardy; *R. ferrugineum* and *R. hirsutum*, dwarf alpine species; *R. campanulatum*, a North Indian species.—*Eng. Cyc.*

Rhododendrons are very numerous at Laghep, near Tumloong, and Dr. Hooker gathered, in two days, seeds, of twenty-four kinds. These occurred in the following order in ascending. Commencing at 6000 feet—1. R. Dalhousiæ; 2. R. vaccinioides; 3. R. camelliæflorum; 4. R. arboreum. Above 8000 feet:—5. R. argenteum; 6. R. Falconeri; 7. R. barbatum; 8. R. Campbelliæ; 9. R. Edgeworthii; 10. R. niveum; 11. R. Thomsoni; 12. R. cinnabarinum; 13, R. glaucum. Above 10,500 feet:—14. R. lanatum; 15. R. virgatum; 16. R. campylocarpum; 17. R. ciliatum; 18. R. Hodgsoni; 19. R, campanulatum. Above 12,000 feet:—20. R. lepidotum; 21. R. fulgens; 22: R. Wightianum; 23. R. anthropogon; 24. R. setosum.—*Hooker Him. Jour. Vol*: II. *page* 197. No rhododendron grows at Churra, but several species occur a little further north—*Hooker H J. Vol* II. *page* 282. On the hill above Choongtam village, in Sikkim, Dr. Hooker gathered, at 5000 to 6000 feet, *Rhododendron arboreum* and *Dalhousiæ*, which do not generally grow at Darjiling below 7,500 feet. Dr. Hooker collected here ten kinds of rhododendron, which, however, are not the social plants that they become at greater elevations. Still, in the delicacy and beauty of their flowers, four of them, perhaps, excel any other, they are *R. Aucklandii*, whose flowers are five inches and a half in diameter; *R. Maddeni*, *R. Dalhousiæ* and *R. Edgeworthii* all white-flowered bushes, of which the two first rise to the height of small trees.—*Hooker. Him. Jour. Vol.* II. *p.* 25. In the Tonglo mountains, in Sikkim in order of prevalence the trees were,—the scarlet *Rhododendron arboreum* and *barbatum*, the latter thirty to forty feet high as large bushy trees, both loaded with beautiful flowers and luxuriant foliage; *R. Falconeri*, in point of foliage the most superb of all the Himalayan species, with trunks thirty feet high, and branches bearing at their ends only, leaves eighteen inches long: these are deep green above, and covered beneath with a rich brown down. Next in abundance to these were shrubs of *Skimmia*, *Laureola*, *Symplocos*, and Hadrangea and there were still a few purple magnolias, very large *Pyri*, like mountain ash, and the Common English yew, eighteen feet in circumference the red bark of which is used in Nepal as a dye, and for staining the foreheads of Brahmins.—*Hooker. Him. Jour. Vol.* I. *p.* 167.

(7100) RHODODENDRON ANTHROPOGON AND R. SETOSUM, two dwarf species with strongly scented leaves occur at an elevation of 12,000 feet near Wallanchoon in East Nepaul.—*Hooker, Vol.* 1. *p.* 220

(7101) RHODODENDRON ARBOREUM, True Rhododendron, has lanceolate leaves, acute, silvery beneath, tapering to the base; pedunculs and calyxes woolly; segments of corolla 2-lobed, with crenulating curled margins, capsule 10-celled, tomentose. It is a native of the warmer parts of India, and is one of the most beautiful of all trees, but too delicate to bear the open air in England. A steep ascent, in the Ryott valley in Sikkim, led through large trees of *Rhododendron arboreum.–Hook. Him. Jour. Vol.*II. *p.* 190.

(7102) RHODODENDRON ARBOREUM, *Variety roseum*, this, a variety of *R. arboreum*, grows to the height of thirty and forty feet in Sikkim.—*Hooker. Him. Jour. Vol.* I. *p.* 167.

(7103) RHODODENDRON ARGENTEUM. WHITE FLOWERED RHODODENDRON TREES, are found in Sikkim, at an elevation of 8671 feet.—*Hooker.* Rhododendron argenteum is a tree 30 feet high, having leaves very beautiful in the

af-buds, erect and silky, at first enveloped in rge scales, so closely imbricated and so large s to resemble the cones of some species of pine, ie outer or lower scales broad and coriaceous, labrous, coloured (reddish-brown), the innermost nes oblong spathulate, *pubescent*. The flowers re 2 to 3 inches long, 2 to 2½ inches in diame-er, always white. —*Eng. Cyc*

(7104) RHODODENDRON AROMATICUM, Royle. Its leaves, "talesfur" are in India employ-d in medicine.—*Beng. Ph.* 222. The leaves of *Rhododendron aromaticum* (of Royle), are highly ragrant and stimulating; they are brought from Cabul, and called *Talesfur*. (*Royle's Illustrations*, . 259).—*O'Shaughnessy, page* 425.

(7105) RHODODENDRON BARBATUM, a tree from 40 to 60 feet high, branched from he base. Flowers of a moderate size, of a deep ance or blood-colour, collected into a compact globose head, from 4 to 5 inches in diameter. t is one of the most beautiful of the Himalayan pecies, and is readily distinguished by its hav ng bristly petioles and numerous branches flori-erous at their apices.—*Eng. Cyc.*

(7106) RHODODENDRON CAMPANULATUM is said to be Rhododendron anthropogon. Don. or Rhododendron aromaticum. Wall. t vegetates on the Cashmere mountains; its leaves are officinal in Cashmere and Lahore, where they are administered as errhine, to produce sneezing.—*Thirty-five years in the East by Honig. p* 335. The leaves are imported from Thibet and Cashmere, under the names *Burg-i-tibbut* and *Hoolas Cashmeree*, and are used by the natives as a snuff —*O'Shaughnessy, p.* 425.

(7107) RHODODENDRON CINNABARINUM. The leaves of ("Kema Kechoong," Lepcha: Kema signifying Rhododendron) this species alone is said to be poisonous; and when used as fuel, it causes the face to swell and the eyes to inflame; of which Dr. Hooker observed several instances —*Hooker.*

(7108) RHODODENDRON CHRYSANTHUM has acute leaves attenuated at the base, oblong, glabrous, reticulately veined, and of a rusty colour beneath; flowers and buds clothed with rusty tomentum; pedicels hairy; calyx hardly any; segments of the corolla rounded; ovarium tomentose. It is a native of Siberia on the highest mountains, and of the Caucasus. The plant and its effects were first described by Gmelin and Steller, who mention it as used in Siberia for the cure of rheumatism; with us it is used in decoction as a substitute for colchicum. —*Eng. Cyc.*

(7109) RHODODENDRON DALHOUSIÆ is parasitical on the trunks of large trees, especially oaks and magnolias. It has large flowers, three to seven, in a terminal umbellate head, the spread of which is greater than that of the leaves. The calyx large, deeply-divided almost to the base into five ovate elliptical very obtuse spreading foliaceous lobes; corolla very large, 3½ inches to 4½ inches long, and as broad at the mouth, campanulate, white, with an occasional tint of rose; in size and colour and general shape almost resembling that of the white Bourbon Lily, very frequently having the odour of the Lemon.—*Eng. Cyc.*

(7110) RHODODENDRON FALCONERI, a white flowered species, never occurring below 10,000 feet above the level of the sea, is one of the most striking and distinct of the genus.—*Eng. Cyc.* It occurs in East Nepal, where it grows to a height of forty feet with leaves nineteen inches long.—*Hooker. Vol.* I, *p.* 272. This species, in point of foliage, is the most superb of all the Himmalayan species, with trunks thirty feet high, and branches bearing at their ends only, leaves 18 inches long. These are deep green above and covered beneath with a rich brown down.—*Hooker.*

(7111) RHODODENDRON HODGSONI. Its foliage is of a beautiful bright green, with leaves sixteen inches long: Its bark is as delicate as tissue paper and of a pale flesh colour.—*Hooker. Vol.* I. *p.* 259.

(7112) RHODODENDRON LANCIFOLIUM is a shrub 6 or 8 feet high; the bark reddish, papery, easily separating and falling off. Branches spreading, tortuous, wrinkled, and knotted: flowers of a moderate size, collected into a rather dense head at the ends of the branches; corolla of a rich purple colour.—*Eng. Cyc.*

(7113) RHODODENDRON NIVALE This, the most alpine rhododendron, spreads its small rigid branches close to the ground.—*Hooker. Him. Jour. Vol.* II. *page* 135.

(7114) RHODODENDRON PONTICUM is the species to which most of the varieties of English gardens belong. The leaves are oblong-lanceolate, glabrous on both surfaces, attenuated towards the thick petioles, with a streak on the upper surface and of a wide lanceolate form, racemes short and corymbose. It is a native of Asia Minor in Pontus, and of Gibraltar, Spain, and the Caucasus, in wet places, in beech and alder coppices. The corolla is large, purplish, with ovate, acute, or lanceolate segments. The calyx minute, 5-toothed, somewhat cartilaginous. At one time it was supposed that it was this plant which rendered the honey of Asia Minor poisonous, but it has been ascertained that the effect is really produced by *Azalea Pontica.*—*Eng Cyc.*

(7115) RHODODENDRON PUNICEUM.
Kaephul Hind.

A common tree on the lower ranges of the Himalaya hill, the bark called Kaephul is brought to Ajmere, from Delhie and Mirzapoor, and is used as a rubefacient and sternutatory. Dr Irvine found Kaephul and pounded ginger, mixed, the best substance with which to rub cholera pati-

ents to promote reaction: one maund costs five Rupees. The fresh flowers are pleasantly acid, and are eaten by the hill men to quench their thirst during the ascent of the hills, the flowers are also made into a jelly.—*Gen. Med. Top. p.* 147.

(7116) RHODODENDRON WALLICHII is a very distinct and handsome species, with lilac-coloured flowers. Its leaves are quite unlike any Indian species, and the flowers in colour and size resemble those of the much cultivated *R. Ponticum*.—*Eng Cyc.*

(7117) RHODYMENIA, is an ill-defined genus of Algæ, of the order Rhodymeniaceæ, and will probably be divided into several distinct genera; many of the species, especially of the section *Calophyllis* are among the most splendidly coloured of crimson and carmine *Algæ*. Others, as *R. Hombroniana*, are clothed in royal purple; while others, like the sober dulse, of British coasts, *R. Palmata*, have often as much of brown as of purple in their attire.

(7118) RHODYMENIACEÆ, an order of *Algæ*, consisting of purplish or blood red Sea-Weeds, with an expanded or filiform inarticulate frond, composed of polygonal cells, occasionally traversed by a fibrous axis.—*Eng. Cyc.*

Many of the *Rhodymeniaceæ* are valuable in an economic sense.—*R. palmata*, the Dulse of English coasts, is collected largely in Scotland and Ireland, and forms an important article of diet. Many of the *Gracilariæ* are largely used in the East as ingredients in soups and jellies, and also as substitutes for glue.

(7119) *Gracilaria spinosa*. One of this order, *G. spinosa*, is the Agar Agar of the Chinese, and is largely collected both for culinary purposes, and as a component part of one of the strongest Chinese glues. It has recently been imported into England, and is occasionally used instead of carrageen moss in making jellies and blancmanges.—*Eng. Cyc.*

(7120) RHUBARB. RHEUM.

Rawund, ARAB.	Reobarbaro, IT.
Ta-hwang, CHIN.	Rheum, LAT.
Tahoan, COCH-CHIN.	Rawund, PERS.
Rhubarber, DUT.	Ruibarbo, PORT.
Rhubarbe, FR.	Reven, RUS.
Rhabarber, GER.	Ruibarbo, SP.
Rawunchenee, GUZ. HIND.	Variattoo kalang, TAM.

Rheum, Radix, Root, of an undetermined species of Rheum, *Linn.*, of R. palmatum, L. D. and of R. undulatum. The name Rheum is derived from the ῥῆον of Dioscorides; but his description does not well apply to modern Rhubarb. This was, however, known to Paulus Ægineta, &c. The Arabs were acquainted with several kinds, as Indian, Khorassanee, Chinese (their *rawund sini*). The Persians give *reon* as the Greek synonyme of their *rawund*, which is Rhubarb, and of which the plant they say is called *ribas*. Rhubarb is no doubt the rootstock of a species of Rheum, but the species is still unknown. Dr. Royle, after giving (Him. Bot. p. 314—318) an account of the commerce of Rhubarb, stated that "This would bring the Rhubarb country within 95° of E. long. and 35° of N. latitude, that is, into the heart of Tibet. As no naturalist has visited this part, and neither seeds nor plants have been obtained thence, it is as yet unknown what species yields the Rhubarb." This seems now the general opinion. Sievers, an apothecary sent in 1790 by the Russians to investigate the subject, had previously said, that "his travels had satisfied him that as yet nobody, that is, no scientific person, has yet seen the true Rhubarb plant." Dr. Fischer when in London, subsequent to the above publication, informed the author that all the information obtained of late years in Russia, only confirmed what was previously known, that *Rheum palmatum* is not the species, but that the genuine plant is a small one with roundish denticulate leaves. So, more recently, Calau, apothecary in the Rhubarb factory at Kiachta, says: "All that we yet know of the Rhubarb plant or its orgin is defective and wrong; every sacrifice to obtain a true plant, or the seed, has been in vain; nor has the author been enabled to obtain it." Dr. Falconer entered Tibet from the side of Cashmere, and proceeded as far as the Muztah range, or about long. 77° E. and lat. 36°, a region where Rhubarb is sent as a present to the Chief Ahmed Shah from the true Rhubarb country, but was unable to learn anything respecting commercial Rhubarb. He discovered new species of Rheum, and obtained specimens of genuine Extract of Rhubarb *ossareh-rewand*, or Rhubarb-juice, a name which he as well as Dr. Royle found applied in north-west India to Gamboge. He also found Rhubarb-root employed there as a yellow dye. Some information might probably be procured respecting Rhubarb from the traders to Upper Assam.

(7121) *Rheum*: *Linn. Enneandria Monog. Linn.* Flowers complete; perianth petaloid, 6-parted, with equal segments. Stamens usually 9, inserted in pairs into the base of the 3 outer segments, and singly into the 3 interior; filaments subulate; anthers versatile. Ovary triangular, 1-celled. Ovule single, basilary, orthotropous. Styles 3, short, reflexed. Stigmas 3 entire, subdiscoid, spreading. Achænium 3 cornered, broadly winged, supported by the withered perianth at the base. Seed erect, triangular. Embryo straight, antitropous, in the axis of farinaceous albumen. Cotyledons flat, radicle short, superior.

Herbaceous plants, with perennial and branching rootstocks, which are thick and succulent. Stem of most 4 to 10 feet high, except in No. 1 and 2. Leaves large, more or less cordate, wavy at the margin, sheathing at the base, either all radical, or where cauline, alternate. Inflorescence paniculate, or spicato-racemose. The species are valuable not only on account of their root-

stocks or Rhubarb, but also from the agreeable acidity of their leaf-stalks, employed for making sherbets, tarts, &c. They inhabit cold parts of the world, as the southern part of Russia, Siberia, Tibet, the north of China and the Himalayan mountains, also Affghanistan and Persia. Hence all may be grown in the open air in Europe, and several are so cultivated. As no species seems more entitled than another to be considered as yielding either the Russian or Chinese Rhubarb of commerce, we shall briefly enumerate all, without describing any.

With Spike-like Racemes.

(7122) *a. Rheum Spiciforme, Royle.* (Illustr. Himal. Bot. p. 318. t. 78.) Kherang Pass and other places in Kunawar. Found by Dr. Falconer in Tibet.

(7123) *b. R. Moorcroftianum, Royle,* (*l. c.* p. 318. Lindl. Med. Bot. p. 356.) Niti Pass in the Himalayas. Found by Dr. Falconer in Tibet. These two species differ in their inflorescence from the other described species. Their roots are more dense in texture and of a more yellow colour than those of *R. Emodi* and *R. Webbianum* The powder of both is of a light and bright yellow colour. Dr. Falconer met with both in Tibet, and discovered another species of this group. It is probable that the commercial species will be found to resemble these in habit, from being indigenous, like them in the elevated, arid, and cold regions of Tartary.

With Compound Racemes.

(7124) *c. R. emodi, Wall* Bot. Mag. t. 3508 *R. Australe*, Don. Sweet Fl. Gard. t. 269. Nees von E. Suppl. t. 31. A. and B. Lindl. Fl. Med. p. 354.

(7125) *d. R. Webbianum, Royle, l c.* p. 318. t. 78, a. Choor Mountain. Niti Pass. This yielded the Rhubarb submitted to experiment by Mr. Twining. Trans. Med. Soc. Calc. iii. p. 439.

(7126) *e. R. Ribes, Linn.* Dill. Elth. t 158. f. 192. An. Mus. 2. t. 49. *Ribas* and *rivash* of the Affghans and Persians. much celebrated among them, and much esteemed on account of the agreeable acid of its leafstalks The root is said to be *raeund*. It is the *Riwas* of Serapion, who mentions it as making a good sherbet. It is said also to be found on the mountains of Syria.

(7127) *f. R. Rhaponticum Linn.* Alpin Rhapont, i. t, 1. Nees von E. 113-14-15. Borders of the Euxine, and on the north of the Caspian Sea. Deserts near the Volga. and in Siberia, as it is known to yield Siberian Rhubarb. Supposed to have yielded the Rhabbarum of the ancients. Cultivated in Great Britain on account of its stalks, and extensively at Banbury on account of its roots, and also at Rheumpole near Lorient, in the department of Morbihan in France.

(7128) *g. R. crassinervium Fischer.* Sent from St. Petersburgh to the Apothecaries' Garden at Chelsea. Roots large, and said to have the colour and odour of Turkey Rhubarb.

(7129) *h. R. leucorrhizum Pallas* R. nanum, *Sievers.* Ledebour, Il. Pl. Ross. t. 492. Found in the deserts of the Kirghis, and South of Siberia, and Altai Mountains. Said to yield *White* or *Imperial Rhubarb.*

(7130) *i. R. Undulatum, Linn.* Amœn. Acad. iii. t. 4. Nees von E. 116, 117. St. and Ch. 177. Lindl. Fl. Med. p. 357. A native of Siberia, Tartary, and China? Seeds of what was called the genuine Rhubarb plant were given to Kauw Boerhaave by a Tartarain merchant, and these seeds produced this species and *R. palmatum*, both of which are admitted as officinal in the D. P. This is said to be cultivated in France as one of those yielding French Rhubarb.

(7131) *j. R. Caspicum, Fisch.* Caspian Shores and Altai Mountains Lindl. p. 557.

(7132) *k. R. Compactum, Linn.* Mill. Dict. 2 8. Nees von E. 121. A native of Chinese Tartary, said to yield some of the Rhubarb cultivated in France, which forms a fair imitation. Valued in Britain on account of its stalks.

(7133) *l. R. Palmatum Linn* L.D. This species easily distinguished from the others by its roundish, cordate, half palmate leaves, with the lobes also deeply cut. Root large, branched, brown externally, of deep yellow internally. Supposed to be a native of the mountains of Mongolia near the great wall of China. The seeds of this were received by K. Boerhaave with those of *R undulatum* as those of the genuine Rhubarb; and it is thought, when cultivated in Europe, to resemble Chinese-Russian Rhubarb more closely than any other kind. in taste, odour, internal structure, and the action of some chemical reagents.

(7134) *m. R. Hybridum. Murray*, is a doubtful species, but is remarkable for the great size of its roots as cultivated both on the Continent and in this country. This plant with R. Rhaponticum, compactum, and emodi, with hybrids from them, are those most commonly cultivated in great Britain on account of their stalks.

The greater part of the Rhubarb of commerce grows in Chinese Tartary, on the mountains and plains surrounding Lake Kokonor (*Pallas and Rehman*), especially in the province of Gan-su (or *Kansu? Calaw*) and is gathered in summer from plants of six years of age. When dug up, it is cleansed, peeled, cut into pieces bored through the centre, strung on a string, and dried in the sun. In the autumn it is brought to Sinin, where Bucharian traders reside, and from thence sent to the Russian frontier town of Kiachta, and to Pekin, Canton, Macao. Considerable care is bestowed at the Russian factory in examining and separating the good from the inferior pieces, also from impurities; and in paring the Rhubarb to remove remaining portions of the bark, also the upper part of the root, and in perforating all

pieces so as to examine their interior; because many, though sound externally, soon decay internally, from the rapid drying it is thought. Dr. Royle, however, found most old roots of R. Webbianum more or less decayed. It is collected in quantities of 4[illegible],000 pounds before it is imported into the European parts of Russia, and is packed in bags, and placed where there is a free current of air, afterwards in chests.

(7135) *Russian*, called also *Turkey Rhubarb*, but which in Russia is called *Chinese Rhubarb*, is imported into the frontier town of Kiachta, and thence sent to Moscow and St. Petersburgh, whence it is distributed to the rest of Europe. It varies in shape, being irregularly roundish, and angular, from the bark having been shaved off with a knife; some pieces are cylindrical, a few flattish, many of them pierced with holes. Externally smooth, of yellow colour; internally, the texture is rather dense; fracture uneven, irregularly marbled with white and red veins, having a strong and peculiar slightly aromatic odour, a bitter, rather astringent taste, feels gritty when chewed, tinges the saliva yellow, and produces a powder of a bright yellow colour. Mr. Queckett obtained from 35 to 40 per cent. of raphides, or conglomerated crystals of oxalate of lime, which are situated within the cells, and which are the cause of the grittiness experienced when Rhubarb is chewed.

(7136) *Bucharian Rhubarb*, which makes its way to Vienna by Brody and Nischny, seems, from specimens and information afforded by Mr. Faber to Dr. Pereira, to be the inferior kinds of the above Rhubarb, and which, as inferred by the latter, would be burnt, if presented to the Russian authorities; it therefore finds its way into Europe by other channels. It is intermediate between the Russian and the Chinese Rhubarb, and generally of inferior quality.

(7137) *Chinese*, sometimes called *East India Rhubarb*, consists of two or three varieties. 1. One called by Dr. Pereira *Dutch trimmed*, or *Batavian Rhubarb*, and, according to the shape, called *Flats* or *Rounds* in the trade, is closely allied to, and is derived, with very little doubt, from the same sources as the Russian Rhubarb; some of which, as mentioned above, finds its way to Canton, and is thence imported into Europe, or first into one of the Indian ports, and thence re-exported to Europe. It resembles the above in appearance, as the cortical portion appears to have been sliced off, and not scraped. The holes with which the pieces are perforated often contain within them pieces of the string by which they had been strung together. 2. Another variety which is more particularly called *Chinese Rhubarb*, also, *half trimmed*, is distinguished from that called Russian, as being irregular in shape, never angular, but the edges rounded, as if the bark, instead of being sliced, had been scraped off, often some of it still remains adherent the roots are, besides, of less uniform good quality than the Russian. Externally or a dull er yellow; many of the pieces heavier from being more compact, the reticulation less regular and of a yellowish-brown colour. 3. A third variety has lately been described by Dr. P. under the name of *Canton Stick Rhubarb*. This is in *cylindrical* pieces about two inches long, and from ½ to three quarters of an inch in diameter These are probably produced in the mountain which bound China, as those of the province o Sechuen, and perhaps of Kansu.

(7138) *Siberian Rhubarb*. Small quantities of this kind have been imported by Mr. Faber and have been proved to be those called by Grassman and others *Siberian Rhapontic Root* This occurs in long, thin, almost cylindrical o spindle shaped pieces, decorticated and perforated by a hole. Colour, externally pale yellow, internally brownish yellow, or reddish white. Odour and taste of good Rhubarb, but weaker; does not feel gritty. Dr. Pereira compares it with English *Stick Rhubarb* (v. P. J. iv. 448 and 500). It has since been proved (P. J. vi. p. 74) that the Rhuburb cultivated at Banbury is yielded by the same species, that is *Rheum Rhaponticum*

(7139) *Himalayan Rhubarb*. This is produced by different species, is of very different quality. That yielded probably by *R Moorcroftianum*, given to Dr. Royle by Major Hearsey, the companion of Mr. Moorcroft, was of a bright but light yellow colour, and, as stated by Dr. Royle in 1827, "appeared both in sensible qualities and medical virtues to equal the best Rhubarb that he had ever seen". (*Trans. Med. Soc of Calcutta*, iii. p. 439.) The Rhubarb of *R. Webbianum* was tried by Dr. Royle in both the Military and the Civil Hospital at Saharunpore, and found to be of very good quality. Some of it was subsequently submitted by the Medical Board to the late Mr. Twining, for experiment in the General Hospital at Calcutta. After trial in 43 cases, he reported that in doses of ℈j. or dr.½ it has a good purgative effect, operating nearly as freely as the best Turkey Rhubarb; and, further, that the effects of small doses of the remedy, as a tonic and astringent, are highly satisfactory; also, that it "is very efficacious in moderate doses for such cases as Rhubarb is generally used to purge." After a further trial in 4 other cases of Diarrhœa, he reports, "If further experiments should confirm the efficacy of the Himalaya Rhubarb in such cases, the acquisition of this remedy to the Materia Medica of this country will be of the utmost importance" (l. c. p. 445). This Rhubarb differs much in appearance from that of commerce. The bark, of a brownish colour, has not been taken off. The texture is radiated, rather spongy, the colour a yellowish brown, the powder of a dull brownish-yellow colour,

with little aroma (but when fresh dried, the the root was described as aromatic by Mr. Twining) with a bitter and rather astringent taste. Dr. Royle selected the branches of the roots, for he found the root-stock generally decayed in the centre. They were cut into short pieces, and slung upon a string for the facility of drying. Some of the Himalayan Rhubarb is probably yielded by R. Emodi, perhaps by other undiscovered species of Nepal, and of the passes towards Bootan. Their value must be decided by their medical effects in the cases for which they are suited, and not by their differing in appearance from the roots of other species.

(7140) *English Rhubarb.* This is cultivated at Banbury, in Oxfordshire, to the extent of twenty tons annually, and is the produce of *Rheum Rhaponticum* (*v.* P. J. vi p. 75). It is the kind frequently sold by men dressed up as Turks as Turkey Rhubarb. The species vary in shape, some being ovoid, others cylindrical (*English Stick Rhubarb*), smoothed externally, and rubbed with a yellow powder; light rather spongy, with a reddish hue. It is rather mucilaginous in taste and a little astringent. Its odour feeble, but unpleasant. It is supposed that much of this is employed for adulterating the Asiatic Rhubarb when in a powdered state (v. P. J. vi. p. 74 and 76.) A variety of analyses of Rhubarb have been made by different chemists, but with such varying results, that Dr. Schlosperger and Dapping say that "not one satisfactory analysis is to be met with."—*Royle.*

The extent of country from which rhubarb of one kind or another is actually collected, according to Christison, stretches from Ludall, in 77½ East longitude, to the Chinese province of Shensi, 29 degrees further East, and from the Suechan mountains, in north latitude 26 degrees, nearly to the frontiers of Siberia, 24 degrees northward. The best rhubarb is said to come from the very heart of Thibet, within 95 degrees east longitude and 35 degrees north latitude, 500 or 600 miles north of Assam. The price of Chinese rhubarb is inferior to that of Russia or Turkey. It varies in China from 38 dollars per picul upwards, and about 1,500 piculs are annually exported, on an average at 500 dollars per picul. In 1844, 2,077 piculs were shipped from Canton for Great Britain; and of 95,701 lbs. imported in 1841, 43,640 lbs. were brought from China, 8,249 lbs. from the Philippines, 7,294 lbs. from the East Indies, and 33,710 lbs. from the United States; only 1,462 lbs. were brought from Russia. The imports from the East Indies, have decreased more than 70 per cent. in the last twelve years, as compared with the preceding. The wholesale prices are, for round rhubarb, 8d. to 3s. per lb.; flat, 6d. to 3s. 3d. per lb.; Dutch trimmed, 6s. to 7s. per lb.; Russian, 13s. to 13s. 6d. per lb. In 1831, England imported 133,462 lbs. from the East India Company's possessions, and 6,901 lbs. Russia. In 1845, only 71,298 lbs. came from the East. From China we received, in 1843, 172,882 lbs.

The quantities of rhubarb on which duty of 1s. per lb. was paid in the six years ending 1840, were as follow: –

	East Indian. lbs.	Foreign. lbs.
1835	32,515	10,647
1836	36,836	7,752
1837	44,669	5,946
1838	37,026	7,402
1839	22,575	12,525
1840	16,745	22,203

The English imports and consumption of rhubarb are thus stated in the *Pharmaceutical Journal* :—

	Imports. lbs.	Consumption. lbs.
1826	102,624	32,936
1831	140,395	40,124
1836	122,142	44,468
1841	95,701	67,877
1846	427,694	0
1847	305,736	0
1848	116,005	0
1849	94,914	0

The rhubarb brought into Siberia grows wild in Chinese Tartary, especially in the province Gansun, on hills, heaths, and meadows, and is generally gathered in summer from plants of six years of age. When the root is dug up, it is washed to free it from earthy particles; peeled, bored through the centre, strung on a thread, and dried in the sun. In autumn all the dried rhubarb collected in the province is brought in horsehair sacks containing about 200 lbs., to Sinin (the residence of the dealers), loaded on camels, and sent over Mongalia to Kiachta, and the ports and capital of China.—*Simmonds.*

(7141) RHUS, the name of a genus of Plants belonging to the natural order *Anacardiaceæ*, and to the tribe *Sumachineæ*. One of the species, *R. cotinus*, appears to have been known to Pliny, who refers to its dyeing properties, and its place of growth, the Apennines, under the name of Cotinus. This genus has an extensive geographical range, from the south of Europe to the Cape of Good Hope. It is also found in Asia and North and South America. Most of the species are poisonous, but they are much cultivated as ornamental shrubs, especially on account of the beautiful red colour of their leaves in autumn. Many of them are used also for the purposes of dyeing and tanning; as an astringent principle, to which is frequently added an acid, is common to the whole genus. The genus *Rhus* has the following characters:— Flowers bisexual, or polygamous; calyx small; persistent, 5-partite; petals 5, inserted under

the margin of the disc, imbricate in æstivation; stamens 5, hypogynous; ovary 1-celled, sessile; fruit, a dry drupe; seed solitary, exalbuminous; radicle opposite the hilum, and bent downwards along the edge of the cotyledons. Leaves alternate, simple, or compound; panicles axillary or terminal. De Candolle enumerates about 90 species, to which other writers have made additions, but there is reason to believe that many of the new species are merely varieties. We shall here enumerate only a few of those which are of interest on account of being cultivated, or their uses in medicine and the arts. Dr. Wight gives *Rhus Bucki-Amela*, 561; *Roxburghii*, 561, *semialata*, var. β *Roxburghii*, 561; succedanea. 560.

(7142) RHUS COPALLINA, Gum-Copal or Mastich-Leaved Rhus. Leaf glabrous above, slightly pilose beneath, 5-7 pairs of leaflets and an odd one, lanceolate and entire; petiole winged and jointed; root creeping; flowers yellowish-green, diœceous. It is a native of North America from New Jersey to Carolina.

(7143) RHUS CORIARIA, Hide, or Elm-Leaved Sumach.

Shumak Pers. | Tumtum, Arab.

A native of Persia, Syria, Palestine, and the south of Europe, about 8 or 10 feet high, divided into numerous irregular branches. All parts of this plant are inodorous, but have a styptic taste; to the abundance of tannic acid it owes its properties and value in the arts; M. Tromsdorf has found in the berries a large quantity of bi malate of lime.—*O'Shaughnessy, page* 282. Leaf 5-7 pairs of villous leaflets, elliptical, bluntly and coarsely toothed, petioles naked. Flowers in large loose panicles of a whitish-green. Drupes villous. This plant is a native of the south of Europe. It is extensively used for the purpose of tanning, and it is said that all the leather made in Turkey is tanned with the bark of this species of *Rhus*. The fruit is acid and astringent, and the seeds are often used as tonics for exciting the appetite.—*Eng. Cyc.*

(7144) RHUS COTINUS. Venus-Sumach, or Wild Olive. Flowers hermaphrodite, arranged in loose panicles of a greenish-yellow colour; leaves simple, entire. This is a very ornamental shrub, and is one of the European species, growing wild in various districts of the south of Europe. It is made use of, like many other of the species, for tanning, in Italy, and is called Scotino. The wood is used by the modern Greeks for dyeing wool, which is said to be of a beautiful rich yellow. It is frequently cultivated on account of its beauty.

(7145) RHUS DECEPIENS. *Wight* Terebinthaceæ, Ill. 75.

Kat poovarasco marum, Tam.

A very fine close grained light coloured wood: judging from a branch specimen it must, if procurable of good size, be one of considerable value.—*Wight.*

(7146) RHUS GLABRA. Smooth-Leaved Sumach. Leaf like the last, but broader and glabrous. Branches also glabrous. Fruit red covered with silky hairs. This species, as well as another named *R. viridifolia* is considered by some botanists as only a variety of *R. typhina* Like the last, this species is abundant in North America, over-running sometimes a whole district, and forming a troublesome weed. Its fruit is very sour, but may be eaten with impunity Bees are very fond of the blossoms.

(7147) RHUS LUCIDA. Terebinthaceæ Shining leaved Sumach, introduced from the Cape. *Riddell.*

(7148) RHUS RADICANS, Rooting Poison-Oak, or Sumach.—Leaf one pair of leaflets and an odd one, odd one petiolated, glabrous entire. A native of America from Canada to Georgia. Its climbing habit, combined with the beautiful red colour of the leaf during decline of the year renders it one of the most picturesque of American plants. It frequently abounds in the forests, where it may be seen covering the tops of the highest trees. It climbs up walls and rocks, and runs upon the ground with equal facility, thus covering everything within the reach of its stems. De Candolle distinguishes three varieties: *R. vulgaris*, with a stem climbing by means of roots; *R. volubilis*, climbing without roots; and *R. microcarpa*, with fruit much smaller than the other two. Like R. Toxicodendron it emits a juice which indelibly stains linen. It is equally poisonous with *R. venenata*. A detailed account of the effects of the genus *Rhus* may be seen in Professor Kalm's 'Travels in North America.

(7149) RHUS TOXICODENDRON, common Poison-Tree, or Poison-Oak.—Leaf of one pair of leaflets and an odd one, with a petiole, inciso-angulate, pubescent; flowers greenish. It is found in woods, fields, and fences, in common with R. Radicans in North America, where they are both known by the same name. Many botanists consider the two only varieties of the same plant. This species is the type of the genus *Toxicoendron* of Tournefort. It was introduced into England in 1640, and first grown in the Bishop of London's garden at Fulham. This species is that which is most frequently used in medicine. The less common species of this genus cultivated in Britain are—*R. pumila* (Dwarf Sumach), *R. viridiflora* (Green-Flowered Sumach), *R. pentaphylla* (Five leaved sumach), *R. suaveolens* (Sweet-Scented Sumach), and *R. aromatica* (Aromatic Sumach).

(7150) RHUS TYPHINA, Fever-Rhus, or Stag's-Horn Sumach. Leaves with 8 10 pair of leaflets and an odd one, lanceolate-acuminate, serrated, pilose beneath. There are two forms of this plant: the one *R. t. arborescens*, in the form

of a tree, from 10 to 25 feet in height; the other *R. t. frutescens*, shrubby, and only from 2 to 10 feet high. The young shoots are covered with down, which, with their somewhat crooked and stunted branches, give them the appearance of young stags'-horns; hence their name. The flowers are in dense spikes, at the ends of the branches, the pistilliferous ones developing themselves into woolly drupes, which are very conspicuous when ripe. It is found in every part of North America, and its dark-red leaves add much to the beauties of an American autumn. The fruit of this plant is exceedingly sour, and on this account it is frequently called vinegar plant, and is even used in some parts as a substitute for vinegar.

(7151) RHUS VENENATA, Poison Sumach, or Swamp Sumach. Leaf 6-7 pair of leaflets, almost glabrous, entire, lanceolate-acuminate, reticulated beneath. Fruit white. It is a native of North America from Canada to Carolina, and also in swampy districts in Japan. This plant is exceedingly poisonous, so virulent that it is said to affect some persons by merely smelling it. A touch will sometimes produce violent inflammation. It is a beautiful shrub, and well worthy of cultivation, but great care should be taken to prevent its being carelessly handled.

(7152) RHUS VERNICIFERA, Varnish-Bearing Sumach, or Japan Varnish-Tree. Leaf with 5-6 pairs of leaflets, all ovate, long, acuminate, entire, glabrous above, velvety beneath. It is a native of Japan and Nepaul. Its leaves are very large and beautiful, rendering it one of the handsomest of shrubs. According to Thunberg, this is the plant which yields the celebrated Japan Varnish.

(7153) RHUS VERNIX, OR VERNICIA. Chinese Varnish Tree. When Mr. Fortune prepared to take up his late residence in China, his attention was directed by the Calcutta Agricultural Society, to the Chinese varnish tree, *Rhus* species, the wax-insect tree, *Fraxinus* species, and to the soap bean tree, *Cæsalpinia* species: to the various trees valuable for their fruit or timber and ornamental plants; but above all to the green indigo (so called), *Rhamnus* species, which yielded a dye that was at that time attracting much attention in France. He says, the tree which yields the Chinese varnish is a species of Rhus which although producing an article of great value is extremely dangerous to use. The varnish is largely used in the country for giving a fine polish to tables and chairs used in the houses of the wealthy. The beautiful lacquer ware so extensively exported from Canton to foreign countries and which is so well known and justly admired, is produced by this tree. It has the valuable property of being less liable than French polish to be injured by a heated vessel which may be placed upon it, but it is very poisonous and requires to be handled with great care by the workmen who use it. Indeed after furniture is dry it is very unsafe for certain constitutions until it has been in use for some time and the smell entirely gone. A friend of mine Mr Jones, American consul at Foochow-foo, used some furniture which had been laquered some time and was apparently quite dry and yet he was very ill for a long time from its effects, so ill that he thought he should be obliged to leave the country and go home. And this is no solitary instance, for I have known several persons suffer most severely from the same cause.—*Fortune's Residence, p.* 146. Williams says, the beautiful appearance of the lacquered-ware of China owes its lustrous coloring to a composition of lampblack and the clarified juice obtained from a species of sumach, called *Rhus Vernix* or *Vernicia*, Wood oils are obtained from other plants of the same family, and the different qualities of lacquered-ware are owing to the use of these inferior ingredients. The real varnish tree is described by De Guignes as resembling the ash in its foliage and bark, it is about fifteen feet in height, and furnishes the sap when seven years old, which is carefully collected from incisions in the trunk opened in the summer nights. The body of the ware is wood partially smoothed, or pasteboard, upon which two or three coats of a composition of lime, paper, and gum are first laid and thoroughly dried and rubbed. The surface of the wood is also hardened by rubbing coarse clay upon it, and afterwards scraping it off when dry. Two coatings of lamp black and wood oil, or in the finer articles, of lamp black and varnish, are laid upon the prepared wood, and after drying, the clear varnish is brushed on, one coating after another, with the utmost care, in close and darkened rooms, allowing it to dry well between the several coats. The articles are then laid by to be painted and gilded according to the fancy of customers, after which a last coating is given them. The varnish is brought to market in brownish cakes, and reduced to its proper fluidity by boiling; it is applied to many purposes of both a varnish and paint, when it is commonly mixed with a red or brown color. A beautiful fabric of lacquered-ware is made by inlaying the nacre of fresh and saltwater shells in a rough mosaic of flowers, animals &c. into the composition and then varnishing it. Another kind, highly prized by the Chinese, is made by covering the wood with a coating of red varnish three or four lines in thickness, and then carving figures upon it in relief. The great labor necessary to produce this ware renders it expensive. A common substitute for the true varnish is the oils of the Dryandra, Jatropha, Croton, and other members of the Euphorbiaceous family, expressed from their seeds by a variety of simple machines, consisting for the most part of different applications of

power to cylinders and pestles by which the seeds are pressed or pounded. The oil after pressing, according to Dr. Gaignes, is broiled with Spanish white in the proportion of one ounce to half a pound of oil; as it begins to thicken, it is taken off and poured into clean vessels. It dissolves in turpentine, and is used as a varnish, either clear or mixed with different colors; it defends woodwork from injury for a long time, and forms a good painter's oil. Boiled with iron rust, it forms a reddish brown varnish. In order to prevent its penetrating into the wood when used clear, and to increase the lustre, a priming of lime and hog's blood simmered together into a paste is previously laid on.—*Williams' Middle Kingdom, Vol.* I. *p.* 121.

(7134) RHUS: *Species.*

Coongilliya marum, Tam. | Bucki amela,

Dr. Wight says, this is the chloroxylon dupada of Buchanan and Ainslie. An undescribed name and judging from the leaves, one not requir d, which are clearly those of a rhus very nearly allied to Roxburgh's R. Buckiamela, but distinct. The qualities of the timber is unknown. The outer sap-wood is waite, fine grained and heavy, apparently very good.—*Wight.*

(7155) RHYNCHOPS ABLACUS, a Shear water occurs at Siligoree in the Terai.—*Hooker. Him. Jour. Vol.* I *p* 399.

(7156) RHYSICOSIA VESTITA, a beautiful purple-flowered leguminous plant with small tuberous roots, is cultivated to some extent in the Khasia Hills.—*Hooker, Him. Jour. Vol.* II. *p.* 287.

(7157) RHYZOMYS CHINENSIS. The Chinese bamboo rat or chuck shu is found in the western part of Kwangtung.—*Williams' Middle Kingdom, p.* 257.

(7158) RIBBON.

Ruben de Soie, Fr.	Nastro di seta, It.
Band, Ger.	Cinta de Seda, Sp.
Fheet, Guz. Hind.	

A name given to silken bands of various widths and colours, much used for trimming bonnets, caps, and other purposes. They are both plain and flowered, and are distinguished into sarecnet, satin, &c, according to the manner in which they are made.—*Faulkner.*

(7159) RICE.

This is one of the most extensively diffused and useful of grain crops, and supports the greatest number of human race. The cultivation prevails in Eastern and Southern Asia, and it is also a common article of subsistence in various countries bordering on the Mediterranean. It is known in the Japan Islands, on all the sea coasts of China, the Philippine and other large Islands of the Indian Archipelago, partially in Ceylon, Siam, India, both shores of the Red Sea, Egypt, the shores of the Mozambique Channel, Madagascar, some parts of Western Africa, South Carolina, and Central America. Three species only are enumerated by Lindley:—*Oryza sativa*, the common rice, a native of the East; *O. latifolia*, a species having its habitat in South America; and *O. Nepalensis*, common in Nepaul. But there are a host of varieties known in the East; these, however, may for all practical purposes, be resolved into two kinds—the upland or mountain rice (*O. Nepalensis*, the *O. montica*, of Roxburgh), and the lowland or aquatic species (*O sativa*).

Rice, the chief food, perhaps, of one third of the human race, possesses the advantage attending wheat, maize, and other grains, of preserving plenty during the fluctuations of trade, and is also susceptible of cultivation on land too low and moist for the production of most other useful plants. Although cultivated principally within the tropics, it flourishes well beyond, producing even heavier and better filled grain. The chief variety of this cereal is cultivated throughout the torrid zone, wherever there is a plentiful supply of water, and it will mature, under favorable circumstances, in the Eastern continent, as high as the 45th parallel of north latitude, and as far south as the 38th. On the Atlantic side of the Western continent, it will flourish as far north as latitude 38 degrees, and to a corresponding parallel south. On the Western coast of America, it will grow so far north as 40 or more degrees. Its general culture is principally confined to India, China, Japan, Ceylon, Madagascar, Eastern Africa, the South of Europe, the Southern portions of the United States, the Spanish Main, Brazil, and the Valley of Parana and Uruguay. In 1834, 29,583 bags of rice were shipped from Maranham. At the Industrial Exhibition in London, in 1851, there were displayed many curious specimens and varieties of rice, grown without irrigation, at elevations of three thousand to six thousand feet on the Himalaya, where the dampness of the summer months compensates for the want of artificial moisture. Among these American rice received not only honorable mention for its very superior quality, but the Carolina rice, exhibited by E. I. Heriot, was pronounced by the jury "magnificent in size, color, and clearness," and it was awarded a prize medal. The jury also admitted that the American rice, though originally imported from the Old World, is now much the finest in quality.

United States.—The present culture of rice in the *United States* is chiefly confined to South Carolina, Georgia, Florida, Alabama, Mississippi,

nd Texas. The yield per acre varies from wenty to sixty bushels, weighing from forty- ive to forty-eight pounds when cleaned. Under avourable circumstances as many as ninety bush- ls to an acre have been raised. Judge Dun- herty, who resides near the borders of Hender- on county, Texas, has raised a crop of several hundred bushels of upland rice. The crop aver- ges thirty bushels to the acre. He thinks rice an be raised there as easily as Indian corn, and will be far more profitable. Another variety is ultivated in America to a limited extent, called Cochin China, dry, or mountain rice, from its daptation to a dry soil, without irrigation. It will grow several degrees farther north or south han the Carolina rice, and has been cultivated with success in the Northern provinces of Hun- gary, China, Westphalia, Virginia and Maryland; but the yield is much less than that already stat- ed, being only fifteen to twenty bushels to an acre. It was first introduced into Charleston, rom Canton, by John Brodly Blake, in 1772.

The *American* crop of rice in 1848, reach- ed 162,058 tierces in market, and of these 160,330 tierces were exported from South Caro- lina. The largest rice crop grown in South Caro- lina for the past thirty years, was in 1847, when 192,462 tierces were raised; 140,000 to 150,000 is about the average, and it has only exceeded 170,000 on four occasions.

Rice being an aquatic plant, is best grown in ow moist lands, that are easily inundated. The ground is ploughed superficially, and divided in- o squares of from twenty to thirty yards in the ides, separated from each other by dykes of earth about two feet in height, and sufficiently broad for a man to walk upon. These dykes are for retaining the water when it is required, and o permit of its being drawn off when the inun- dation is no longer necessary. The ground pre- pared, the water is let on, and kept at a certain eight in the several compartments of the rice field, and the seedsman goes to work. The rice that is to be used as seed must have been kept in the husk; it is put into a sack, which is im- mersed in the water until the grain swells and shows signs of germination; the seedsman, walk- ing through the inundated field, scatters the seed with his hand, as usual; the rice immediately sinks to the bottom, and many even penetrate to a certain depth in the mud.

Piedmont.—In Piedmont, where the sowing takes place at the beginning of April, they gene- rally use about fifty-five pounds of seed per acre.

In *Piedmont* the usual return of a rice field is reckoned at about fifty for one.

Mauritius.—In the *Isle of France* rice is culti- vated in very damp soils, upon which a great deal of rain falls, but which are not flooded, as in other tropical countries: but the process is not so certain nor the crop so great, as when inundation is employed.

At *Mocsa*, in New Granada, the paddy fields which are not inundated, under the in- fluence of a mean temperature of 26 deg. centri- grade (79·0 deg. Fahrenheit), yield 100 for 1.—(Simmonds's "Colonial Magazine," vol. xi. p. 99.)

The rice now grown about *New Orleans* is as sweet, if not sweeter, than that imported from South Carolina, but it is deficient in hardness and brightness when ready for market, a defect owing entirely to two causes, neither of which is beyond the control of the planter. The one cause is the mode of culture, it being generally grown without due attention to the seed—seed- ed at too late a period of the season, and allow- ed to become *rare-ripe* upon the stalk. The other cause is the very imperfect mode of its preparation for market; this being invariably ac- complished by the primitive pestle and mortar, or the old-fashioned "pecker mill." The same seed is planted in the same soil from year to year, a system which, it is generally conceded, will deteriorate the quality and production of any grain crop. A very large proportion of the rice grown in Carolina is prepared for market at the steam toll-mills, in the vicinity of Charleston; and a mill of this description near New Orleans, would remedy the greatest defect in the rice of the country, greatly increase the demand for the article, and undoubtedly yield a large re- turn for the investment. The toll mills at and around Charleston are, and always have been, prosperous. The mills of Mr. Lucas, in England, erected to clean "paddy," *i. e.* "rough rice," sent there in bulk from Carolina, have succeeded also, and have increased the consumption of the article in that country. The "rough rice," "paddy," or grain, as it comes from the ear, is composed, first, of a rough, silicious outer cover- ing, impervious to water, which is very useful in the neighbourhood of cities, for filling up low lots or pools, for horse beds, and for packing crock- ery and *ice*, being far better for the latter pur- pose than the saw-dust used; second, a brown flour or bran, lying directly under the outer co- vering; and third, of the clean or white rice. There is no question that, as a common diet, it is better adapted to the climate of Louisiana than Indian corn; and it can be grown on the hitherto *waste lands of the sugar plantations*; it is always substituted by the physi- cian, when practicable, as the food best adapted to the laborer, in season of diarrhœa and other similar diseases, is *perferred* before any other grain by the negro; and if the clean rice be ground and bolted, a meal is produced which can be made up into various forms of cake and other bread, of unrivalled sweetness and delicacy. The outer flour, or brown bran, which is separ- ated from the chaff at the toll mill, is known as "rice flour," and corresponds to the "bran" of wheat, it is a most excellent food for horses,

poultry, pigs and *milch cows*, and would always command a ready sale in New Orleans. It is used extensively for these purposes at and around Charleston, and is shipped thence, by the cargo, to Boston and other Northern ports. After other great impediments were removed, one formidable difficulty still remained in the way of the rice planters, and that was the threshing of the crop by flail. The labor requisite, to accomplish the threshing was so great, that we once heard a distinguished planter say, while having one large crop threshed out by flail, that he would regard another large crop as a calamity. Previous to 1830 threshing mills had been tried by various individuals, but with no apparent success. In that year the attempt was renewed, and the first trail of a thresher, constructed in New York, was tested on Savannah river, under the auspices of General Hamilton. The machinery was driven by apparatus similar to that employed for driving the cotton gin. The result was not very satisfactory, but there was ground for hope, and after an outlay of very large sums, and after many disappointments the happy expedient was thought of, of testing the mill with steam instead of animal power. The experiment was completely successful, and it was manifest at once that the difficulties had not been in the imperfect construction of the thresher, but in the insufficiency of the moving power. It is now twenty years since the first working of the small mill alluded to, and the rice threshing-mill, with steam engine attached, is now a splendid piece of operative machinery. The rice in sheaf is taken up to the thresher by a conveyor, it is threshed, the straw taken off, then thrice winnowed and twice screened, and the result in some cases exceeds a thousand bushels of clean rough rice, the work of a short winter day. We had the rare opportunity, a few years since, of seeing a Chinese book on rice planting, which contained many engravings. The language we could not read, but we comprehended a sufficient number of the engravings to institute a comparison between their system and our own, and the result was, in our method of irrigation we were their equals, while in economy of cultivation, and in the preparation of the grain for market and for use, we are greatly their superiors. Again, some six or seven years since the East India Company, of London, sent an agent to this country to procure American cotton seed, gins and overseers, for the purpose of testing the practicability of raising cotton by our method in India. This agent, Captain Bayles, when in Savannah, was heard to say that he had especial directions from the Company to inform himself minutely of our system of rice culture. Here, then, was an embassage from the banks of the Ganges, a spot where rice has been cultivated probably for twenty centuries, to inquire into the method of cultivation and preparation, of a people amongst whom the grain had no existenc one hundred and sixty years ago." The follow ing is the mode of culture for rice in Carolina:— It is sowed as soon as it conveniently can b after the vernal equinox, from which period un til the middle, and even the last of May, is th usual time of putting it in the ground. It grow best in low marshy land, and should be sowe in furrows twelve inches asunder; it requires t be flooded, and thrives best if six inches unde water; is occasionally drained off, and turned o again to overflow it, for three or four time When ripe the straw becomes yellow, and it i either reaped with a sickle, or cut down with scythe and cradle, some time in the month o September; after which it is raked and bound, c got up loose, and threshed or trodden out, an winnowed in the same manner as wheat o barley

Husking it requires a different and particula operation, in a mill made for that purpose. Thi mill is constructed of two large flat woode cylinders, formed like mill-stones, with channel or furrows cut therein, diverging in an obliqu direction from the centre to the circumference made of a heavy and exceedingly hard timber called lightwood, which is the knots of the pitc pine. This is turned with the hand, like th common hand-mills. After the rice is thu cleared of the husks, it is again winnowed, whe it is fit for exportation.

A bushel of rice will weigh about sixty-si pounds, and an acre of middling land will pro duce twenty-five bushels.

Various machines have been contrived fo cleaning rice, of which one secured by patent t Mr. M. Wilson, in 1826, and thus described b Dr. Ure, may be regarded as a fair specimen:— It consists of an oblong hollow cylinder, laid i an inclined position, having a great many teet stuck in its internal surface, and a central shaft also furnished with teeth. By the rapid revolu tion of the shaft, its teeth are carried across th intervals of those of the cylinder, with the effec of parting the grains of rice, and detaching whatever husks or impurities may adhere t them. A hopper is set above to receive the rice and conduct it down into the clear cylinder About eighty teeth are supposed to be set in th cylinder, projecting so as to reach very near the central shaft, in which there is a correspond ing number of teeth, that pass freely between th former.

The cylinder may also be placed upright, o horizontal if preferred, and mounted in any con venient framework. The central shaft should b put in rapid rotation, while the cylinder receive a slow motion in the opposite direction. Th rice, as cleaned by that action, is discharged a the lower end of the cylinder, where it falls int a shute, and is conducted to the ground. Th machine may be driven by hand, or by any othe

convenient motive power.—*Dict. of Arts and Manufactures.* The growth of rice in North America is almost wholly confined to two States nine-tenths of the whole product, indeed, being raised in the States Carolina and Georgia. A little is grown in North Carolina, Louisiana, and Mississippi. The aggregate crop, for 1848, amounted to 89,879,185 lbs.; while in 1847 it had risen to 103,000,000 lbs. Besides the *American* rice which is raised in the water, there is also the dry, or mountain rice, which is raised in some parts of Europe on the sides of the hills. It is said to thrive well in Cochin China, in dry light soils, not requiring more moisture than the usual rains or dews supply. By long culture the German rice, raised by the aid of water, is stated to have acquired a remarkable degree of hardness and adaptation to the climate. The upland rice of the United States is thought by some to be only a modified description of the swamp rice. It will grow on high and poor land, and produce more than Indian corn on the same land would do, even fifteen bushels, when the corn is but seven bushels. The swamp rice was originally cultivated on high land, and is not so now, because it is more productive in the swamp, in the proportion, as is said, of twenty to sixty bushels per acre; and the use of water likewise, it is stated, makes it easier of cultivation, by enabling the planter to kill the grasses. It is thought that on rich high land, rice may be made to produce twenty-five or thirty bushels to an acre in a good season. A new variety of rice is mentioned as having been discovered in South Carolina, in 1838, called the big-grained rice. It has been proved to be unusually productive. One gentleman, in 1840, planted not quite half an acre with this seed, which yielded forty-nine and a half bushels of clean winnowed rice. In 1842, he planted 400 acres, and in 1843, he sowed his whole crop with this seed. His first parcel when milled, was eighty barrels, and netted half a dollar per cwt. over the primest rice sold on the same day. Another gentleman also planted two fields in 1839, which yielded seventy-three bushels per acre. The average crop before from the same fields of fifteen and ten acres, had only been thirty-three bushels per acre. The experiment of cultivating rice in France appears to have succeeded perfectly. A piece of ground of 100 hectares in extent (250 acres) was sown with rice in 1851, in the lands of Arcachon, near Bordeaux, and the crop proved a highly satisfactory one. The seed is sown about the middle of April, and almost immediately appears above ground. Rice may be kept a very long period in the rough—I believe a lifetime. After being cleaned, if it be prime rice, and well milled, it will keep a long time in any climate; only when about to be used (if old) it requires more careful washing to get rid of the musty, which accumulates upon it. Some planters—the writer among the number—prefer for table use rice a year old to the new. The grain is superior to any other provisions in this respect. If a laborer in the gold diggings, or elsewhere, takes with him two days' or a week's provisions, in rice, and his wallet happens to get wet, he has only to open it to the sun and air, and he will find it soon dries, and is not at all injured for his purpose. Rough rice may remain under water twenty-four hours without injury, if dried soon after.

Passing eastward, rice begins to be found cultivated in Egypt, becomes more general in Northern India, and holds undisputed rule in the Sea Boards of peninsula of India, in China, Japan, and the Eastern isands—shares it in the west coasts of Africa with maize, which, on the other hand, is the exclusively cultivated corn plant of the greatest part of tropical America, with only some unimportant exceptions. On the coast of Africa rice ripens in three months; they put it under water when cut, where it keeps sound and good for some time.

Rice is now the staple commodity of Bourbon, and it produces about 26,000 quintals annually. It forms, together with maize and mandioc, the principal article of food amongst the negroes and colored people.

The Bhull rice lands of Lower Sind.—Like all large rivers which flow through an alluvial soil, for a very lengthened course, the Indus has a tendency to throw up patches of alluvial deposit at its mouth; and these are in Sind called *bhulls*, and are in general very valuable for the cultivation of the red rice of the country. These *bhulls* are large tracts of very muddy swampy land, almost on a level with the sea, and exposed equally to be flooded both by it and the fresh water; indeed on this depends much of the value of the soil, as a *bhull* which is not at certain times well covered with salt water, is unfit for cultivation. They exist on both sides of the principal mouths of the Indus, in the Gorabaree and Shahbunder pergunnas, which part of the province is called by the natives "Kukralla," and was in olden days, before the era of Goolam Shah Kalora, a small state almost independent of the Ameers of Sind. On the left bank of the mouths of the river these *bhulls* are very numerous and form by far the most fertile portion of the surrounding district. They bear a most dreary, desolate, and swampy appearance—are intersected in all directions by streams of salt and brackish water, and are generally surrounded by low dykes or embankments, in order to regulate the influx and reflux of the river and sea. Yet from these dreary swamps a very considerable portion of the rice consumed in Sinde is produced; and the Zemindars, who hold them, are esteemed amongst the most respectable and wealthy in Lower Sind To visit a *bhull* is no easy matter. Rout by land there is none, and the only way is to go by

boat, in which it is advisable to take at least one day's provisions and water, as the time occupied in the inspection will be regulated entirely by the state of the tide and weather. Very difficult is it too, to land on any of these places the mud being generally two or three feet deep, and it is only here and there that a footing can be secured, in the embankment surrounding the field. Let me now describe the mode of cultivating these anomalous islands, floating as it were in the ocean, and deriving benefit both from it and the mighty river itself, whose offspring they are. Should the river during the high season have thrown up a *bhull*, the Zemindar selecting it for cultivation, first surrounds it with a low bund of mud, which is generally about three feet in height. When the river has receded to its cold weather level, and the *bhull* is free of fresh water (for be it remembered, that these *bhulls* being formed during the inundation, are often considerably removed from the river branches during the low season), he takes advantage of the first high spring tide, opens the bund and allows the whole to be covered with the salt water. This is generally done in December. The sea water remains on the land for about nine weeks, or till the middle of February, which is the proper time for sowing the seed. The salt water is now let out, and as the ground cannot, on account of the mud, be ploughed, buffaloes are driven over every part of the field, and a few seeds of the rice thrown into every footmark; the men employed in sowing being obliged to crawl along the surface on their bellies, with the basket of seed on their backs; for were they to assume an upright position, they would inevitably be bogged in the deep swamp. The holes containing the seed are not covered up, but people are placed on the bunds to drive away birds, until the young grain has well sprung up. The land is not manured, the stagnant salt water remaining on it being sufficient to renovate the soil. The rice seed is steeped in water, and then in dung and earth for three or four days and is not sown until it begins to sprout. The farmer has now safely got over his sowing, and as this rice is not as in other cases trasplanted, his next anxiety is to get a supply of fresh water; and for this he watches for the freshes which usually come down the river about the middle and end of February, and if the river then reaches his *bhull*, he opens his bund, and fills the enclosure with the fresh water. The sooner he gets this supply the better, for the young rice will not grow in salt water, and soon withers if left entirely dry. The welfare of the crop now depends entirely on the supply of fresh water. A very high inundation does not injure the *bhull* cultivation, as here the water has free space to spread about. In fact the more fresh water the better. If, however, the river remains low in June, July, and August, and the south-west monsoon sets in heavily on the coast, the sea is frequently driven over the *bhulls* and destroys the crops. It is in fact a continual struggle between the salt water and the fresh. When the river runs out strong and full the *bhulls* prosper, and the sea is kept at a distance. On the other hand, the salt water obtains the supremacy when the river is low, and then the farmer suffers. In this manner much *bhull* crop was destroyed in the monsoons of 1851 and 1852, during the heavy gales which prevailed in those seasons. The rice is subject to attacks also of a small black sea crab, called by the natives *Kooknee*, and which, without any apparent object, cuts down the growing grain in large quantities, and often occasions much loss. The crop when ripe, which, if all goes well will be about the third week in September, is reaped in the water by men, either in boats, or on large masses of straw rudely shaped like a boat, and which being made very tight and close, will float for a considerable time. The rice is carried ashore to the high land, where it is dried, and put through the usual harvest process of division, &c.: and the *bhull* is then on the fall of the river again ready for its annual pickling.

Ceylon.—The process of preparing the field for rice culture, in the Kandian country, Ceylon, is very simple. When the paddy is to be cultivated in mud, a piece of ground is enclosed in a series of squares or terraces, by ridges raised with mud and turf; a quantity of water is directed into the field from an adjacent stream or tank, and is allowed to remain on it for fifteen days; at the expiration of this time the field is ploughed with a yoke of buffaloes, which operation is repeated at the end of fifteen days more, when, by the rotting of the woods and other matter, the field has become manured. After another interval of fifteen days the field is again ploughed and the broken ridges are repaired. Eight days after the field is harrowed, and subsequently rolled or levelled; and when the water has been let out the seed is sown, having in most instances been previously made to germinate, by being spread on platforms and kept wet. The water is turned in during night, to prevent crabs and insects from destroying the seedlings, and let out during the day; and this they continue to do till the plants attain the height of one foot. Water is only retained in the field until the ears are half ripe, otherwise they would ripen indifferently and be destroyed by vermin. A variety of coast paddy, called "moottoo samboo," was introduced into the Kandian province in 1832, which was found to produce a more abundant crop, by one third, than the native. It is of six months growth.

Kashmire.—In *Kashmire* rice is the staple of cultivation, and the practice adopted there is thus described by a writer in Simmonds "Colonial

Magazine," vol. x. p. 180. It is sown in the beginning of May, and is fit to cut about the end of August. The grain is either sown broadcast in the place where it is intended to stand till it is ripe, or thickly in beds, from which it is transplanted when the blade is about a foot high. As soon as the season will admit, after the 21st of March, the land is opened by one or more ploughings, according to its strength, and the clods are broken down by blows with wooden mattocks, managed in general by women, with great regularity and address; after which water is let in upon the soil, which for the most part of a reddish clay, or foxy earthy, is converted into a smooth soft mud. The seed grain, put into a sack of woven grass, is submerged in a running stream until it begins to sprout, which happens sooner or latter, according to the temperature of the water and of the atmosphere, but ordinarily takes place in three or four days. This precaution is adapted for the purpose of getting the young shoots as quickly as possible out of the way of a small snail, which abounds in some of the watered lands of Kashmir, but sometimes proves insufficient to defend it against the activity of this destructive enemy. When the former suspects, by the scanty appearance of the plants above the water in which the grain has been sown, and by the presence of the snail drawn up in the mud, that his hopes of a crop are likely to be disappointed, he repeats the sowing, throwing into the water some fresh leaves of the Prangos plant, which either poison the snails or cause them to descend out of the reach of its influence. The seed is for the most part thrown broadcast into about four or five inches of water, which depth is endeavoured to be maintained. Difference of practice exists as to watering, but it seems generally agreed that rice can scarcely have too much provided it be not submerged, except for a few days before it ripens, when a dried state is supposed to hasten and to perfect the maturity, whilst it improves the quality of the grain. In general the culture of rice is attended with little expense, although dearer in Kashmir than Hindostan, from its being customary in the former country to manure the rice-lands, which is never done in the latter. This manure, for the most part, consists of rice straw rejected by the cattle, and mixed with cowdung. It is conveyed from the homestead to the fields by women, in small wicker baskets, and is set on the land with more liberality than might have been expected from the distance it is carried. Many of the rice lands are situated much higher than might be thought convenient in Hindostan and are rather pressed into this species of culture than naturally inviting, but still yield good crops, through the facility with which water is brought upon them from the streams which fall down the face of the neighbouring hills. In common seasons the return of grain is from thirty to forty for one, on an average, besides the straw.—*Simmonds*

Himalaya.—A species of hill rice grows on the edge of the *Himalaya* mountains. The mountain rices of India are grown without irrigation, at elevations of 3,000 to 6,000 feet on Himalaya, where the dampness of the summer months compensates for the want of artificial moisture. The small reddish Assamese rices, which become gelatinous, in boiling, and the large, flat-grained, soft, purple-black Ketana rice, of Java and Malacca, shown at the Great Exhibition, were curious.—*Simmonds.*

Bengal.—The rice of *Bengal* by the exercise of some care and skill, has recently been so far improved as nearly to equal that of the Carolinas. Dr. Falconer has introduced into India the numerous and fine varieties of rice cultivated in the Himalayas; of these some of the best sort were at his suggestion distributed to cultivators along the Doab canal. On the cultivation of *rice*, the staple food of the lower provinces, and on the various crops sown after the early rice has been gathered in, as well as on the general appearance and condition of the successive umbrageous villages, wide plains, and deep or rapid rivers which make up lower Bengal, a good deal has been written in the Calcutta *Review;* and for a general description of the alluvial soil of lower Bengal we refer to Art. I. Vol. IX. The early, or *aous* rice is sown generally on high, light, and sandy soils from March to May, as showers may be favourable. It is cut variously from the end of July to the middle or end of September, and in six weeks' time, it is succeeded by what is known as 'cold weather' crop, which may be mustard, vetches, pulse, millet, *sola*, or gram, barley, oats, and the like. The *aumon* rice is sown in rich, deep, and loamy soils from April to June, and is reaped any time between the beginning of December and the end of January. It is a richer, stronger, and every way a better crop than the *aous*, but it is more exposed to inundation, and is not followed by any second crop within the year. Occasionally the early and the late crops are sown on the same land, and cut without injury to each other at different periods. A large part of the late rice is planted with the hand in rows, on land carefully ploughed, cleaned, and smoothed for the purpose. It is everywhere known as the *roa*, and yields an abundant harvest. A third kind of rice, unknown in high and dry tracts of country, but very common in extensive marshy districts, is called the *boru*, and, from its proximity to water, is sown and grown from the month of January to the end of May. It is cultivated in places where there is too great a depth of water during the heavy rains, and consequently abundance to keep the plant moist during the fierce heat of summer. The early rice, in the most favourable

season, from both grain and straw, cannot give more than five rupees per beegah. In bad seasons it may not yield more than one rupee. As much as ten or even fifteen rupees may be got from the *aumon* crop in good seasons; but when heavy rains, or unexpected inundations from large rivers, drown the young plants, as was the case during 1855 and 1856, and may be the case again at any time, the return is positively nothing. The *boro* rice may be expected to yield seven or eight rupees per beegah. And on these three crops, over some hundreds of miles, the hopes and anxieties of some millions hang for a large part of the year. About the crops, there can be little dispute. The condition of those who live by such crops, we have found to be as follows:—Take a large plain, a crowded bazar on market day, or a high road between two towns or villages of any importance, and it will generally be found that the men at work on the one, or buying and selling in the other, or sturdily strutting along the third, have some title, or right, or interest, or occupancy in the soil. Nearly every man has his *jumma*, which, in plain language, is his tenant-right of occupancy, or of proprietorship. The extent of this *jumma* is, in conversation, and for all practical purposes, indicated not by the acre-age, for few can tell the area of their possession, but by the rent demanded, for every man well knows how much he is expected to pay. A *jumma* or *jote* may then vary from five rupees to one hundred rupees. It will usually be found to be from about twelve to thirty. Obviously, the possibility of a man's paying such rent, and yet finding enough to support him, will depend, apart from all fluctuations of climate, on the rent, compared to the productiveness and extent of the tenure, on the number of mouths which he has to support in his own homestead, and on the number of sharers who have a joint hold on the land. The shareholders in a large *jumma* of eighty or one hundred rupees we have known to reach to ten, and there are often as many as four or five on a small holding of twenty rupees. This is an inevitable consequence of the law of subdivision; but it is remarkable, how constantly this terminates, after two or three generations, in a separation of cousins, and a division of the inheritance into two or more shares, no longer to be held in common: and it is still more remarkable how this universal custom is rudely set to rights by the progress of disease, by fever, cholera, small-pox, and other scourges, which clear off whole families, and cause the inheritance to revert to the hands of a single member. If on the one hand, numerous instances may be found of families branching out, till they seem to weigh down the minute holding,—on the other, cases as frequent will occur, where father, and uncles, with their offspring, have all been swept away, and the patrimonial inheritance has reverted to a single individual, with, it may be, the surviving female relations all dependent upon his exertion for bread. The *jumma* or holding will naturally be divided between a homestead, or *beeta*, with it may be, some garden land attached to it, and the outfield in the plain, with its early or late rice, or both. The main question relative to outfield and infield will, of course, be the average amount of rent. We have said that few ryots know the extent of their holdings in actual *beegahs*. This is the case, in many instances where the land has never been measured, when it will be loosely stated at twenty or thirty beegahs but where it has been measured, the ryot unluckily knows its extent but too well. There is in every pergunna a variable rate of assessment but one well understood. In pergunnah Insanuggur it is one thing; in pergunnah Zalimpore it is another. There is, we say, a general understanding, expectation, or regular consent given, or implied, that it shall not be enhanced without some very special reason. And the question to which we now come, and which is one of the last importance, is, what is the usual average, and is it a fair one? On this point, custom and opinions vary so much in different places, and according to the different views of payers and receivers, that it is with some difficulty, and after a great deal of research, that we have arrived at a definite conclusion. Even in villages, a higher rate on the homestead and the garden, is universal. It may be as low as Rs. 2, or as high as Rs. 3-8 or Rs. 4, but the average may be taken at Rs. 2-8 or Rs. 2-12. Such rate, in itself, is nothing intolerable. What is a fair rent for the land which yields one splendid crop, or two average crops in the year? We find that the rent of this land varies from as low as 8 annas a beegah to Rs. 2-13 and even Rs. 3, which is pretty much the same as saying that rent in England ranges from eighteen shillings or one pound an acre to fifty and fifty-five shillings. In Bengal the extremes are rare. The land may be too sandy, or too low, or too sterile, or impregnated with salt, or culturable only after a rest for a year or ten months, and in these cases, a rate of from ten to fourteen annas is quite as much as it can bear. If rich and loamy, it may well bear from eighteen annas to Rs. 1-4. But repeated investigation has satisfied us, that a ryot holding a *jote* of twenty beegahs, composed of homestead high land, and deep land, pays on the whole a higher rate than this. Were the whole of the twenty beegahs assessed at no more than a rupee per beegah, we should have little to say in favour of a reduction. But when the homestead pays Rs. 2-8 or Rs. 3, the deep rice land Rs. 1-8 Rs. 1-12 or Rs. 2, and the lighter soils from twelve annas to Rs. 1-2, as we have found that they do pay repeatedly, it is clear that the ryot has a burden laid on him, which it requires con-

stant exertion, without intermission from sickness, litigation, or any other cause, as well as a succession of favourable seasons, to enable him to support. In round numbers one rupee a beegah, or Rs. 1-2, and perhaps Rs. 1-4 in very favourable localities, would be a fair and equitable assessment. But we find in some *perguunahs*, that Rs. 1-4, and in others that Rs. 1-6, and Rs. 1-12, or Rs 2 are the regular rates. Add to this occasional cesses, with an increasing family, and the families of other shareholders increasing as well, and it is very conceiveable that the ryot has no easy task to perform. We have found *zemindaries* where the best soils were taxed at no more than Rs. 1-2 a beegah, and the worst as low as eight annas. We can point to others where the same soils are taxed respectively at Rs. 1-4 and Rs. 2-8. The difference between the condition of the cultivator, in each instance, is almost as easy to compute as the difference of the above sums.

To meet the rent as above described, the ryot or tenant proprietor cultivates his land in one of the three following ways: 1, by his own thews and sinews: 2, by the labour of hired servants: 3, by the system of *burga*. By far the greater part of the rice crop is sown and grown by those to whom the holding belongs. The ploughing, crushing, and harrowing, the casting of the seed, the weeding during the rainy season, the cutting and carting, are most frequently all done by the holders of the *jote*. Hired labour is, obviously, an indication of some advance in civilization, or of some substance and well-being. It is the frequent resource of men who have taken service under Government, or under Zemindars, or who have some other means of livelihood, or who with an under tenure, comprising one or more villages, retain in their own hands a small home farm. The third method of cultivation is very frequent. The proprietor having neither the skill, nor the time, nor the muscle, to sow and plough himself calls in a person whom he terms the *bargadar*. This person brings his own plough, bullocks, and seed, and his own person and goes through all the agricultural operations, which commence in April and end in December. Having done this without any advances from the proprietor,—who does not always give one-half the seed, as stated by Mr. Wilson in his glossary,—the bargadar, at harvest-time, gets for his pains, just one-half the crop. The arrangement suits the convenience of both parties. The tenant is saved the exertion of cultivating and can follow any other business. The bargadar, who may work in one village this year, and in another the next, is saved anxieties about leases, exactions, bonuses, and payments of rent, &c. In the very worst of seasons, he has lost nothing beyond his seed and his labour. But of the three methods of cultivation, the most frequent as well as the most successful, is the first. We have heard ryots admit that, if a man wanted careful ploughing, sowing, and planting, the young plant to be well weeded, and the surplus water to be regularly carried off, with a first-rate crop at the end of all, there was nothing for it but to do everything himself. We have heard from Englishmen many philanthropic complaints of indifferent agriculture, coarse implements, perfunctoriness in the manual operations, and bad crops. We are ready to admit that the tools are primitive, that the ryot is often lazy, and that there is little change in the system of cropping from one year to another; but the charge of bad results for *common*, and not *unusual* crops, we entirely deny: nay, we are fully prepared to go further, and show that not in any part of England itself, with all the elaborate ploughs of modern invention, are there to be shown such specimens of finished and successful husbandry. We have seen, this year soil crushed, smoothed, and weeded, till it more resembled a suburban garden on the South-western railway line, than a common piece of rice land in the plains of Bengal. There may be a field for improvement or experiment in the various crops, other than rice, which are sown and cut from the commencement to the close of the cold season. A knowledge of the best system of rotation, and of the best and simplest ways of manuring and irrigating such crops, is what the ryot has not got, and what it would be well to give him; fruit trees and vegetables, if properly looked to, would become more valuable. And there is little doubt that as railways are extended through eastern and northern Bengal, there will be many more inducements to the ryot to cultivate those productions, which find a ready sale only in large stations and prosperous cities. But, with all this a very large surface of ground will ever remain fitted for rice cultivation alone. This must be the case until scientific men shall discover some means of draining off the accumulation of water of the rainy seasons, which the thousand natural outlets of the country have yet failed to do; or some article of general consumption be found, which possesses the peculiar faculty of growing in from six inches to feet six of water, and which, with a fair chance given it will beat Neptune in a race for life or death. On the other hand, we are ready to admit that there may be several places, where by cutting a canal and letting the water run off into some deep river, having its exit in the Sunderbunds, a good many acres of land might be saved from annual inundation, and bear crops of rice, instead of jungle with a broad blade. But such places are suited to engineering and not to agricultural triumphs; and we must again repeat our conviction that persons intending to teach the ryot some parts of his trade, would be rather surprised to find how very much they had yet to learn. His knowledge of seed-time, and of har-

vest, and the general water-shed of his part of the country, is hardly susceptible of improvement; while the pains and labour, though unwilling, with which considerable patches of ground are cleaned and smoothed for the reception of rice plants, dibbled in by rows, with the hand, after being grown in a sort of nursery, as well as the results of these diverse operations, would be worthy of all praise in an agricultural show in England. We must now say a word or two on the implements, by which these gratifying results are attained. Most readers must have seen a Bengali plough at some time, or have seen its print. Looking like a rude sort of anchor, it might excite the contempt of a sturdy English yeoman, or the surprise of the classical student who remembered the unmanageable instrument described by Virgil in a well-known passage of the Georgics. But this rude implement is suited to the means and capacity of the ryot, and to the bullocks which are to draw it. The price of this and other necessary tools may not be unacceptable to some of our readers. A very common thing is for the ryot to find his wood, *baubul* or mangoe, the former being preferred for its hardness, as well as the piece of iron for the share, and then to go to the carpenter of the village, who for a remuneration of four annas, will "fix" him a plough! It is usual too, to give this functionary a general retainer for the year, in the shape of a maund of rice in the husk, in consideration of which he is to make and repair the plough and other agricultural weapons; or the ryot may buy his plough ready made. In any case the whole expense will not exceed Rs. 1-4 or 1-8 for wood, iron, and workmanship; and the article may last one, two, or even three years. The prices of bullocks, which draw the plough or the cart, if the ryot is lucky enough to possess one, vary according to the size and strength of this animal. A young and vigorous bullock will fetch from eight to ten, twelve, and even sixteen rupees. Twenty rupees for a good pair is not an uncommon price. Weak and puny animals, or those whose best days are past, will cost four, five, or six rupees each. Eight rupees is about an average price. After the plough comes naturally the harrow. But this implement is a very different affair from the iron-toothed harrow of Europe. It is nothing more or less than two bamboos tied parallel to each other by cross pieces of wood, so as to form a regular ladder about eight feet long. The bullocks being harnessed, a couple of men take their stand on the ladder, so as to increase its weight, when it is dragged repeatedly over the field on which the seed has been cast, till every clod is pulverised, and the whole surface is perfectly smooth. We might term this a clod-crusher; the natives call it a *bida* or *bichara*. It costs about two annas, and may be put together by the ryot himself, The instrument which resembles a harrow, i that it shows one single row of wooden teeth, not employed till the seed has shot up some ir ches above the ground, when it performs some what of the duty which the 'scuffler' performs i England, preventing the soil from caking an hardening, without tearing up the young an tender plant. This instrument may be purcha ed for about six annas. Add to this a sma hand-spud for weeding, which costs about thre pice; a fish basket to catch, rather than to carr fish, which costs about three annas; a triangul fish net, which is worth about five annas; *kodali* or mattock, which, however is not un versally needed, worth little more than a rupee; *doa* or bill-hook worth about eight or ten anna —and we have the complete stock in trade of very considerable portion of the labouring popula tion of Bengal. So much for the implements of th ryot. Take them altogether, we do not think it ur warantable to assert that of acute misery, helples indigence, and downright wretchedness, there i really very little in Bengal. Heat is at least a bearable as extreme cold. They have not had famine for three quarters of a century, and it i only this year 1857 that we had complaints fron some quarters that the ryot, owing to the scarcit and dearness of rice, has not had his two meals day. The poor man has in this country, like th poor man elsewhere, a certain amount of inevita ble hardship. Agricultural operations deman *considerable*, not to say severe, labour. A ryot we will say, gets up in the morning, when he eat his *pan* and *supari*, or betelnut and leaf, if he ca afford it, or takes a few whiffs of his hookah Going to the field about eight, nine, or ten o'clock, he comes home for his mid-day meal, ex cept at ploughing-time, when if delay be highly objectionable, his food is sent out to him by one of his sons or nephews. After eating, he returns to work again, often till past sunset. An active limbed man will plough one beegah a day, but will drive the clod-crusher or the harrow over eight or ten times that extent. It is a very good day's work, when weeds are plentiful, to clear one quarter of beegha of rice land, if so much. And to plant a whole beegah with rice stalks, sown elsewhere and transplanted at a favorable mo ment, is enough for three men in a day. This latter operation is especially fatiguing, as the workman is constantly in a stooping position. Weeding is comparatively easy, though the feet and ancles are soaked in mud and water for hours, because the ryot literally squats down with an umbrella of matting fixed tightly over his head, without a handle, and moves on gradually as he clears a little circle around him. A pleasing feature in these operations is the invariable custom of the ryots to help each other. Half the village turn out and weed the plot of Gopal one day, of Tin Kouri the next, and of Panchoo on the third. The rice gets thus a regu-

RICE.

lar clearing on one and the same date, and two or three clearings are enough for an ordinary crop.

Arracan.—The fertility of the province of *Arracan* is very great, its soil being fit for the culture of nearly all tropical productions; rice, however, is alone cultivated to any great extent; the low alluvial soil which extends over the whole country, from the foot of the mountains to the sea, being admirably suited for its growth. About 115 square miles are under culture with rice. The export trade in rice of the district, is seen by the following statistical return; and it gives employment to from 400 to 700 vessels, aggregating 60,000 to 80,000 tons.

QUANTITY OF PADDY AND RICE EXPORTED FROM AKYAB, THE PORT OF ARRACAN.

1846	193,267	101,465

—(Simmonds' "Colonial Magazine," vol. xii., p. 462.)

From *Tavoy* and *Mergui*, rice was exported; equal in value to 41,000 rupees, in 1846; 100 baskets of 12 seers each, are equal to 30 Bengal maunds. The basket of rice named above, is equal to 55½ lbs. English Paddy means rice in the husk—rice, the grain when unhusked—a distinction to be kept in mind. The daily average consumption of rice in a family of five, is rated in the Straits' Settlements at three and a quarter chupahs.

The *Burmese* and *Siamese* are the grossest consumers of rice. A common laboring Malay requires monthly 30 chupahs, or 56 pounds of rice, value 3s. 9d. or 4s. The Burmese and Siamese about 34 chupahs, or 64 pounds.

Rice land in *Penang* yields a return which cannot be averaged higher than seventy-five fold—or nearly thirty guntangs of paddy for each orlong (1⅓ acres); but it has been considered advisable to rate it there at sixty fold only.

The rice land of *Province Wellesley* gives an average return of 117½ fold; the maximum degree of productiveness being 600 guntangs of paddy to an orlong of well flooded, alluvial land, or 150 fold, equal to 300 guntangs of clean rice, weighing nearly 4,520 English pounds. The present average produce has been very moderately estimated at 470 guntangs the orlong of paddy. The quantity of seed invariably allotted for an orlong of land is four guntangs. In Siam, forty fold is estimated a good average produce. At Tavoy, on the Tenasserim coast, the maximum rate of productiveness of the rice land was, in 1825, and is still believed to be, nearly the same as the average of Siam; while their *average* was only twenty-fold.—(Low, on "Straits Settlements.")

Rice in *Cochin-China* is the "staff of life," and forms the main article of culture. There are six different sorts grown: two on the uplands, used for confectionery, and yielding only one crop annually; the other sorts affording from two to five crops a year; but generally two, one in April and another in October; or three when the inundations have been profuse.

China.—The late Dr. Gutzlaff stated, at a meeting of the Statistical Society of London, that the population of *China* was about 367,000,000, and the returns of the land subject to tax as used in rice cultivation there, gave nearly half an acre to each living person; and he further stated that in the southern and well watered provinces, it is anything but uncommon to take two crops of rice, one of wheat, and one of pulse, from the same land in a single season. Rice is the only article the Chinese ever offer a bounty for; the price fluctuates according to the seasons, from one and three-quarter dollars to eight dollars per picul. Siam and the Indian Islands, particularly Bali and Lombok, supply the empire occasionally with large quantities. The price of rice in China varies according to the state of the canals leading to the interior; if they are full of water the prices rise; if on the contrary they are low, prices fall in proportion at the producing districts. The amount of consumption is controlled, in a considerable degree, by the cost of transit; when this is cheap prices rise from the general demand; but when land-carriage to any extent has to be resorted to, they fall; it raises prices so much at any great distance, that rice must be used very sparingly, from its enhanced price. It is obvious that if the waters are sufficiently high to allow a boat to pass fully loaded, she does so at an expense of nearly 50 per cent. less than she would do, if, from want of water, she could only take half the quantity; when transport is cheap every one obtains a full supply; when it is dear the

rice districts have more than they can consume. In England, people are so much accustomed to the facilities of transit offered by railroads, canal boats, &c., that we do not readily take into consideration, that in China, except by water, all articles are conveyed from one place to another on men's shoulders. Taking the population of Canton at the usual estimate of a million, and allowing to each a catty a day, the quantity of rice required for one day's consumption alone in that city would be 10,000 piculs, of 133 lbs. each= 1,340,000 lbs.—*Simmonds' Comml. Products.*

During the growth of the rice the fields are always kept flooded when water can be obtained. The terraces near the base of the hills are supplied by the mountain streams, and the fields which are above the level of any adjoining river or canal are flooded by the celebrated water wheel, which is in use all over the country. These machines are of three kinds. The principle in all of them is the same, the only difference being in the mode of applying the moving power, one is worked by the hand another by the feet and the third by an animal of some kind, generally a buffaloe or bullock. The rice lands are kept flooded in this way until the crops are nearly ripe, when the water is no longer necessary. It is also necessary or at least advantageous to go over the ground once or twice during the summer, and stir the soil up well amongst the roots, at the same time removing any weeds which may have sprung up. If the weather is wet, the fields retain the water for a considerable time, and then it is not an uncommon sight to see the natives wading nearly up to the knees in mud and water, when they are gathering in the harvest. In the Island of Chusan, and over all the rice country of Checking and keangsoo, there are two plants cultivated in the winter months, almost exclusively for manure; the one is a species of Coronilla; the other is Trefoil, or clover. Large ridges not unlike those on which gardeners grow celery, are thrown up on the wet rice-fields in the autumn, and the seeds of the plants are dropt in, in patches at five inches apart, on the surface of the ridges. In a few days germination commences, and long before the winter is past the tops of the ridges are covered with luxuriant herbage. This goes on growing until April, when it is necessary to prepare the ground for the rice. The ridges are then levelled and the manure plants are scattered in a fresh state over the surface of the ground. The fields are flooded, and the plough and harrow are employed to turn up and pulverise the soil. The manure thus scattered over the ground and half buried amongst the mud and water, begins to decay immediately, and gives out a most disagreeable putrid smell. This mode of manuring is generally adopted in all the rice lands in this part of China, and the young paddy doubtless derives strong nourishment from the ammonia given out in the decomposition of this fresh manure. Firewood is so scarce in the country that a great portion of the straw, cotton stalks, and grass which would go to manure the fields, is used for firing, and therefore, the plan of growing manure for the land is forced upon the farmers by necessity. The plan of using manure in a fresh state, instead of allowing it first to decay, has doubtless been found from long experience to be the best for the young paddy. The Chinese farmer is not a Chemist, he knows little or nothing of vegetable physiology, but his forefathers have hit accidentaly upon certain systems which are found in practice to succeed and to these he himself adheres and hands them down unchanged to his children.—*Fortune's Wanderings, page* 308.

Java is the granary of plenty for all the Eastern Archipelago; and the Dutch East India Company occupies itself in this culture with solicitude, well persuaded that a scarcity of rice might be fatal to its power. Ordinances to encourage and increase this branch of agriculture have been promulgated at different times by an authority called to watch over the physical well being of many millions of inhabitants.

As an evident proof that the culture of rice, of which it would be difficult to fix the quantity produced annually, increases considerably, I may mention that the exportation from Java, in 1841 was 1,488,350 piculs of 125 Dutch lbs.

Rice is cultivated in Java in three systems. The name of *sawah* is given to the rice fields which can be irrigated artificially; *tepar*, or *tagal* are elevated but level grounds; and *gagah*, or *ladang*, are cleared forest grounds. The two last only give one crop; a second crop may be obtained from the *sawah*, which then most commonly consists of *katjang*, from which oil is extracted in *kapus* or fine cotton, and in *ubie*, a kind of potato.

There are, says Mr. Crawfurd, two distinct descriptions of rice cultivated throughout the Indian islands, one which grows without the help of immersion in water, and another for which that immersion is indispensably requisite. In external character there is very little difference between them, and in intrinsic value not much. The marsh rice generally brings a somewhat higher price in the market. The great advantage of this latter consists in its superior fecundity. Two very important varieties of each are well known to the Javanese husbandman, one being a large, productive, but delicate grain, which requires about seven months to ripen, and the other a small, hardy, and less fruitful one, which takes little more than five months. The first we constantly find cultivated in rich lands, where one annual crop only is taken; and the last in well watered lands, but of inferior fertility, where two crops may be raised. Both of these, but particularly the

marsh rice, is divided into a great number of sub-varieties, characterised by being awned or otherwise, having a long or round grain, or being in color black, red, or white. The most singular variety is the *Oryza glutinosa*, of Rumphius. This is never used as bread, but commonly preserved as a sweetmeat. The rudest, and probably the earliest practised mode of cultivating rice, consists in taking from forest lands a fugitive crop, after burning the trees, grass, and underwood. The ground is turned up with the mattock, and the seed planted by dibbling between the stumps of trees. The period of sowing is the commencement of the rains, and of reaping that of the dry seasons. The rice is of course of that description which does not require immersion. The second description of tillage consists also in growing mountain or dry land rice. This mode is usually adopted on the common upland arable lands, which cannot conveniently be irrigated. The grain is sown in the middle of the dry season, either broadcast or by dibbling, and reaped in seven or five months, as the grain happens to be the larger or the smaller variety.

The culture of rice by the aid of the periodical rains forms the third mode. The grain being that kind which requires submersion, the process of sowing and reaping is determined with precision by the seasons. With the first fall of the rains the lands are ploughed and harrowed. The seed is sown in beds, usually by strewing very thickly the corn in the ear. From these beds the plants, when 12 or 14 days old, are removed into the fields and thinly set by the hand. They are then kept constantly immersed in water until within a fortnight of the harvest, when it is drawn off to facilitate the ripening of the grain.

The fourth mode of cultivating rice is by forcing a crop by artificial irrigation, at any time of the year; thus, in one field, in various plots, the operations of sowing, ploughing, transplanting, and reaping may be seen at the same period.

The fertile, populous, and industrious countries of the *Eastern Archipelago* export rice to their neighbours. The most remarkable of these are Java, Bali, some parts of Celebes, with the most fertile spots of Sumatra, and of the Malay Peninsula. Rice is generally imported to these western countries from those farther east, such as the Spice Islands. Java is the principal place of production for the consumption of the other islands, and the only island of the Archipelago that sends rice *abroad*. The rice of the eastern districts is generally superior to that of the western. The worst rice is that of Indramayu, which is usually discolored. The subdivision of the province of Cheribon, called Gabang, yields rice of fine white grain, equal to that of Carolina. The rice of Gressik preserves best. All Indian rice is classed, in commercial language, into the three descriptions of table rice, white rice, and cargo rice. From the limited demand for the first, it is only to be had in Java, in small quantity. For the same reason the second is not procurable in large quantity, unless bespoken some time beforehand; but the third may be had at the shortest notice in any quantity required. Java rice is inferior in estimation to that of Bengal or Carolina in the markets of Europe. The following statistics show the extent and progress of the culture in Java:—

	In 1840.	In 1841
No. of Residencies in which rice is cultivated	18	18
No. of Regencies	69	68
„ Districts	414	414
„ Desas or Villages	39,931	36,296
Amount of the population who take a part in it, without distinction of caste	6.704,797	6,857,372
Number of families &c.	1,466,845	1,475,675
„ „ families who devote themselves to the cultivation	1,150,406	1,146.083
Number of men bound to obligatory service	1,321.767	1,325,746
Cleared grounds in *bahus*. of 71 decametres	1,470,047	1,540,054
Upon this extent the population had cultivated for the government, in *bahus* of 71 decametres	78,182	74,277
Extent of fields which the population had cultivated on their own account, in *bahus*, &c.	1,286,139	1,361,216
Extent of land in fallow in *bahus*, &c.	105,726	84,561
Produce in piculs of fields cultivated by the population on its own account	21,273.278	23,810,573
Average Produce of a *bahu*.	16½	17
Gross amount of the land tax of 1840	8,502,402fl.	9,030,761fl.
Extent of rice fields newly cultivated in *bahus*	10,328	13,561

This comparative summary shows that the culture of rice increases yearly, and that the average produce of the fields is also continually increasing. These results have been obtained by the attention paid to the proper irrigation of the soil fit for this culture; and to the hydraulic works which the Government executes on its own account in the parts of the island where rice fields can be established, and where they are required to feed a population whose number is still increasing yearly. I have seen, continues Mr. Crawfurd, lands which have produced, from time beyond the memory of any living person, two yearly crops of rice. When this practice is pursued, it is always the five-months grain which is grown. The rapid growth of this variety, has, indeed, enabled the Javanese husbandman, in a few happy situations, to urge the culture to the amount of six crops in two years and a half. Rice cultivated in a virgin soil, where the wood has been burnt off, will, under favorable

circumstances, give a return of twenty-five and thirty fold. Of mountain rice, cultivated in ordinary upland arable lands, fifteen fold may be looked upon as a good return. In fertile soils, when one crop only is taken in the year, marsh rice will yield a return of twenty-five seeds. When a double crop is taken, not more than fifteen or sixteen can be expected. In the fine province of Kadu, an English acre of good land, yielding annually one green crop and a crop of rice, was found to produce of the latter 941 lbs. of clean grain. In the light sandy, but well watered lands of the province of Mataram, where it is the common practice to exact two crops of rice yearly without any fallow, an acre was found to yield no more than 285 lbs. of clean rice, or an annual produce of 560 lbs.—(*"History of the Indian Archipelago."* The low estimation of Java rice is not attributable to any real inferiority in the grain, but to the mode of preparing it for the market. In husking it, it is for the want of proper machinery, much broken, and, from carelessness in drying, subject to decay from the attack of insects and worms. When in the progress of improvement more intelligent methods are pursued in preparing the grain for the market, it will equal the grain of any other country. Machinery must be employed for husking the grain, and some degree of kiln drying will be necessary to ensure its preservation in a long voyage. I know nowhere that rice is so cheap as in Java, except in Siam, whence it is exported at one-third less cost. A great deal of rice is exported from Siam to China by the junks, and also occasionally a little from Java.

The quantity exported from Java in	1830	was	13,521 coyans
" " "	1835	"	25,577 "
" " "	1839	"	1,103,378 piculs.
" " "	1841	"	676,213 "
" " "	1843	"	1,708,774 "

Rice is grown to some extent in the Dutch portion of Celebes; it yields at a minimum one hundred and fifty fold. The average annual delivery of rice to the Government pays sixty cents for a measure of forty pounds. That which is sold for the consumption of the inhabitants may be procured at the public warehouse for a guilder the 35½ lbs.; and that which is sold for export may be had at public auction for 125 florins the coyan of 3,000 lbs.

Philippines.—The following description of some varieties of rice cultivated in the Philippine islands, is given by Mr. Rich, botanist to the United States Exploring Expedition. The varieties are very numerous; the natives distinguish them by the size and shape of their grain, viz:

a. Binambang.—Leaves slightly hairy; glumes whitish; grows to the height of about five feet; flowers in December: aquatic.

b. Lammyo greatly resembles the above; is more extensively cultivated, particularly in Bantamgas, where it forms the principal article of food of the inhabitants of the coast: aquatic.

c. Malagcquit.—This variety derives its name from its being very glutinous after boiling; it is much used by the natives in making sweet or fancy dishes; and also used in making a white-wash, mixed with lime, which is remarkable for its brilliancy, and for withstanding rain, &c.: aquatic.

d. Malagcquit.—With smooth leaves, and red glumes (all the preceding are whitish); possesses all the qualities of the aquatic variety of the same name—that of being very glutinous after boiling. This rice is said to be a remedy for worms in horses, soaked in water, with the hulls on; it is given with honey and water.

e. Bontot Cabayo.—Common in Ilocos, where it is cultivated both upland and lowland; it produces a large grain, and is therefore much esteemed, but has rather a rough taste.

f. Dumali, or early rice.—This rice is raised in the uplands exclusively, and derives its name from ripening its grain three months from planting; the seed is rather broader and shorter than the other varieties; it is not extensively cultivated, as birds and insects are very destructive to it.

g. Quinandu, with smooth leaves.—This variety is held in great estimation by the people of Batangas, as they say it swells more in boiling than any other variety; it is sown in May, and gathered in October: upland.

h. Bolohan.—This variety has very hairy glumes; it is not held in much esteem by the natives, but it is cultivated on account of its not being so liable to the attacks of insects and diseases as most of the other upland varieties.

i. Tangi.—Leaves slightly hairy, glumes light violet color. This upland variety is held in much esteem for its fine flavor.

Manilla. 435,067 arrobas of rice were exported from Manilla in 1847. A simple but rude mill is in use in Siam, and many parts of India, for hulling paddy, which is similar to those used 4,000 years ago. It consists of two circular stones, two feet in diameter, resting one on the other; a bamboo basket is wrought around the upper one, so as to form the hopper. A peg is firmly set into the face of the upper stone, half way between its periphery and centre, having tied to it by one end a stick three feet long, extended horizontally, and attached by the other to another stick pending from the roof of the shed under which the mill is placed. This forms a crank, by which the upper stone is made to revolve on the other set firmly on the ground. The motion throws the rice through the centre of the stone, and causes it to escape between the edges of the two.

More starch is contained in this grain than in wheat. Braconnet obtained from Carolina rice 85·07, and from Piedmont rice 83·8 per cent. of starch. Vogel procured from a dried rice no less than 98 per cent. of starch. There are several patent processes in existence for the manufacture of rice-starch, which are accomplished chiefly by digesting rice in solutions, more or less strong, of caustic alkali (soda), by which the gluten is dissolved and removed, leaving an insoluble matter composed of starch, and a white substance technically called fibre. Under Jones's patent, the alkaline solution employed contains 200 grains of real soda in every gallon of liquor, and 150 gallons of this liquor are requisite to convert 100 lbs. of rice into starch. In manufacturing rice-starch on a large scale, Patna rice yields 80 per cent. of mark table starch, and 8·2 per of fibre, remaining 11·8 per cent. cent. being made up of gluten, gruff, or bran, and a small quantity of light starch carried off in suspension by the solution. Jones's process may be thus described:—100 lbs. of rice are macerated for 24 hours in 50 gallons of the alkaline solution, and afterwards washed with cold water, drained, and ground. To 100 gallons of the alkaline solution are then to be added 100 lbs. of ground rice, and the mixture stirred repeatedly duing 24 hours, and then allowed to stand for about 70 hours to settle or deposit. The alkaline solution is to be drawn off, and to the deposit cold water is to be added, for the double purpose of washing out the alkali and for drawing off the starch from the other matters. The mixture is to be well stirred up and then allowed to rest about an hour for the fibre to fall down. The liquor holding the starch in suspension is to be drawn off and allowed to stand for about 70 hours for the starch to deposit. The waste liquor is now to be removed, and the starch stirred up, blued (if thought necessary), drained, dried and finished in the usual way.—*Pharmaceutical Journal, Vol.* III. *p.* 138.

Rice is imported into England in bags of 1¼ cwt., and tierces of 6 cwt., not only for edible purposes, but when ground into flour, for cotton manufactures, in aiding to form the weaver's dressings for warps. Rice-meal is commonly used for feeding pigs.

Imported.

The quantity of rice retained for British consumption, by the corrected returns, in 1850, was 401,018 cwts. and 35,119 quarters; in 1851, 399,170 cwts. and 31,481 quarters; in 1852, 574,819 cwts. and 23,946 quarters. The aggregate imports range from 40,000 to 80,000 tons annually, of which about 500 to 800 tons are in the husk.—*Simmonds, p.* 304.

Burmah and Tenasserim.—Rice is universally cultivated, and cultivation has produced many varieties. The Karens have distinctive names for more than forty, and Karen mountain rice is preferred by many to that which is raised by the Burmese on the low lands; yet it is said not to be so nutritious, and on this account bears a less price in the bazar. It is of all colors from ivory-white to coal-black. Of the black rice the Karens prepare a kind of bread, which to them supplies the place of gingerbread. A portion of seethed rice is poured into a large mortar with a prodigious quantity of sesamum seeds. Two women then take their strong ebony pestles and pound it, striking alternately until it becomes a light bounding mass. It is then thrown upon the eating stand, when the whole family seat themselves around it in oriental style, and dissever it with their sabres.

The Karens have another mode of preparing this kind of rice, which is particularly convenient for travellers. A quantity unboiled is thrust into joints of small bamboo, a little water added, and the orifice closed up. It is then roasted, and if eaten with a little butter and salt it is most delicious. The Karens select only two varieties of bamboo for this purpose, and these impart to the rice a sweet delicate flavor.—*Mason.*

India, generally.—The great staple of India, rice, is produced in every variety of soil, at every altitude and in every latitude. To name a tithe of the varieties grown would prove a tedious and useless task, for they vary with every district in which they grow. The finest of these, which is the Bengal table rice, is inferior to the Carolina kind, whilst the great bulk of them would be unmarketable in Europe, from their poverty of body and the slovenly manner in which they are prepared. The Arracan rice is a greyish opaque grain, used in England only for manufacturing starch. Copious irrigation is required for all these varieties; the Himalayan and other hill rices alone requiring no such aid, the cultivation, at times as much as 6000 feet, securing them from the great heat to which the other varieties are exposed. Within the pro-

vince of Bengal, as well as in the Madras low lying districts, the principal cultivation is that of rice. In most other districts this vegetable is comparatively rare. There is a great variety of the grain, differing widely in colour, shape, and weight; but the ordinary description grown does not extend beyond three or four varieties. The first sowing takes place between the end of March and the latter part of May; and as it matures and ripens within a period of about ninety days, it follows that the harvest takes place between the end of July and the middle of September. This crop is taken from sloping ground not subject to inundation, and is by far the safest, though not by any means the most abundant.

Another sowing takes place on low alluvial tracts between the middle of May and the end of June, and requiring five months to reach maturity, will be cut between November and January. This is usually the most profitable harvest, although, from the position of the land, liable at certain times to be seriously damaged by inundations; when, indeed, it is not an unsual thing for entire fields to be swept into the rivers. With some cultivators a practice prevails of *planting out* their rice from nurseries reared near their dwellings. In this case the corn is removed when about eight or nine inches high, carried carefully to its destination, which will be some spot that was, perhaps, not available at the proper sowing time; and there the young stalks will be planted in rows, and pressed down about the roots with an inclination towards the direction whence the prevailing wind blows These plants are said to thrive remarkably if properly placed, and to attain maturity in an incredibly short space of time. Sometimes a heavy flood will unexpectedly sweep away his first planting, in which case the ryot, nothing disheartened, sets to work, and repeats the task, knowing well that if it thrives it will amply repay him for his labour by its heavy crops. After the rice-harvest the ground will be sown with some of the innumerable grains met with in India; in some cases with barley, in others with gram, a kind of pulse admirably suited for the food of horses.—*Cappell's Three Presidencies.*

Rice of India, compared with American rice.—The only causes to be found for the falling off in America in the shipments and in price, (as it has not arisen from over production), are the imports of rice and paddy from Arracan, Patna, and Benares. In Arracan, taking the bulk, the Arracan rice is some 500 per-cent. cheaper than American rice in their different countries.

The Arracan sells in England for 10s or $ 2½ the cwt.
„ American. „ „ „ „ 18 or 4½

Therefore it is, although the American grain, brings 80 per cent. better prices, and freight must also be lower, that the Arracan rice is ousting the American. Why the East Indians are able to undersell the American planter, will be readily perceived from the following, which I have already stated in the Charleston Courier, &c., viz. the rice planter in India, with his wife and family, labor, in the field. The economy of the people is striking. The man's clothing consists of a strip of coarse cotton that passes between his legs, one end attached before, the other end behind, to a string that surrounds his waist. Two pieces of such clothing, of the best description, will last a couple of years; and all his year's clothing will not cost 50 cents. The diet of the people is rice, (which sometimes they use in a raw state, simply steeped in a little water), which when cooked, they eat with some few cooked vegetables mixed up with pepper, chillies turmeric, ginger, and clarified butter. Sometimes instead of vegetables they have fish, and if a goat be killed in the village, then there may be flesh instead of vegetables and fish. A man may support himself for 50 cents a month which is about the value of one rupee of their money.—*Bonynges America, page* 45.

(7160) RICE-BIRD, one of the names of the Paddy Bird, Paddee Bird, or Java Sparrow. It is the *Loxia oryzivora* of Linnæus. This well-known bird, whose plumage is well described by Buffon as being so well arranged that no one feather passes another, whilst all appear covered with that kind of bloom which is visible on plums, giving them a beautiful tint, has the bill very much developed; indeed, with the exception of *Pyrenestes* and perhaps *Coccothraustes*, this finch is the most remarkable of the race for the size and power of that organ. The colour of this bird is bloomy lead-coloured; head and tail black: bill red; belly obscurely rosy; cheeks in the male snowy; legs flesh-coloured. In Java, where it is called Glate, and the other parts of Asia where it is found, it has a very bad reputation on account of the ravages which it commits in the rice-fields with its powerful and sharp bill. In Sumatra the name of the bird is Boorong Peepee. It is often brought alive to England and confined in aviaries for the sake of its elegant shape and graceful colouring: its song, which is short and monotonous, does not much recommend it. This species must not be confounded with the Rice-Bird of America, *Emberiza oryzivora*, Linn.—*Eng. Cyc.*

(7161) RICE-FLOUR. Oryza Sativa; The seeds of rice contain a much less proportion of nitrogenised compounds than the other cereal grains, and particularly wheat: viz. about seven per cent:—The quantity of fatty matter is also less, and, though much difference of opinion has prevailed in reference to the value of rice as an article of diet, analysis clearly proves that it is the least nutritious of all the cereal grasses. This difference of opinion has probably arisen from the fact that rice is seldom eaten by itself, but is partaken of usually with milk, butter, or sugar,

the nutritious properties of which substances have been attributed to the rice itself.—*Hassell.*

(7162) RICE GLUE, or JAPANESE CEMENT, is made by mixing rice flour intimately with cold water, and boiling the mixture. It is white, and dries nearly transparent, hence its use in making many articles in paper. When made with a smaller quantity of water, models, busts, &c., may be formed of it.—*Tomlinson.*

(7163) RICE PAPER, ARALIA PAPYRIFERA, is brought from China in plain and dyed sheets and not unfrequently with various coloured designs on them.—*Faulkner.* The source of this product continued long a matter of doubt, but it is now equally certain that it is produced from the Aralia papyrifera. We refer to that article, as also to article Paper-Rice, for notices of this substance, but now confine attention to the true plant. The rice paper plant (Aralia papyrifera) presented to Mr. Fortune by J. C. Bowring, Esq., of Hongkong, was introduced to India, and is now a remarkable object of great interest in the Calcutta gardens —*A Res. among the Chi. p.* 197. About Yoksun in Sikkim, which occupies a very warm sheltered flat, many tropical genera occur, such as tall bamboos of two kinds, grasses allied to the sugar-cane, scarlet *Erythrinæ*, and various *Araliaceæ*, amongst which was one species whose pith was of so curious a structure, that Dr. Hooker had no hesitation in considering the then unknown Chinese substance called rice-paper to belong to a closely allied plant. The Chinese rice paper has long been known to be cut from cylinders of pith which has always a central hollow chamber, divided into compartments by septa or excessively thin plates. It is only within the last few years that the above supposition has been confirmed, by Sir William Hooker receiving from China, after many years of correspondence, specimens of the rice paper plant itself which very closely resembles, in botanical character as well as in outward appearance of size and habit, the above Sikkim plant.—*Hooker Jour. page* 359.

(7164) RICINUS, an apetalous genus of plants belonging to the natural order *Euphorbiaceæ*. This word is derived from 'ricinus,' the Latin name for a species of insect which the fruit of this plant was supposed to resemble. (Pliny. 'Nat. Hist,' xv. 7.) The common name of *Ricinus* is Palma Christi, a name applied to these plants by Brunfels, Matthiolus, and other older botanists, on account of the form of its elegant lobate leaves. It was originally a native of Asia, but is now naturalised in Africa, America, and the south of Europe. The characters of this genus are:—Flowers monœcious; calyx 3- 5-parted, valvate; no petals; filaments numerous, polyadelphous: style short; stigmas 3, bipartite feathery; ovary globose, 3 celled with an ovule in each cell; fruit capsular, tricoccous; leaves alternate, stipulate, palmate, glands at apex of petiole; flowers in terminal panicles; trees, shrubs, or herbs, becoming arborescent.—*Eng. Cyc.*

(7165) RICINUS COMMUNIS, CASTOR OIL PLANT. Fructibus minoribus. Palma Christi Plant.

The Oil.

Sitti-amunakei yennai, TAM.	Chittamudialoo noo-na, TEL.
Barcek erundie ka tael. HIND.	Tangan-tangan, PHILIPPINE.
Jarak, MALAY. & JAV.	
Kaliki, SUNDA & MAD	

Ricinus Communis or common Palma Christi, is best known as producing castor-oil. It has peltate palmate leaves, with lanceolated serrated lobes; an herbaceous glaucous stem, of a purplish red-colour upwards, and flowers in long green and glaucous spikes springing from the divisions of the branches, the males from the lower part of the spike, the females from the upper; the capsules are prickly. It varies in size; in Britain it is seen seldom more than three or four feet in height, but in India it is a tree; and Clusius mentions it as measuring from two to four feet round its stem in Spain. Lindley refers several species distinguished by Willdenow to this form, namely, *R. viridis*, *R. Africanus*, *R. lividus*, and *R. inermis*. ('Flora Medica.') *R. communis*, will grow freel in Great Britain, and when sown in pots or hotbeds early in the season, and transplanted in spring, it forms a very handsome border annual.—*Eng. Cyc.* Two varieties of the Ricinus communis, one bearing small and the other large seeds, are produced all over India. The small seeded variety yields the best product, and is employed in preparing the oil exported for medicinal purposes

Mode of Preparation.—The fresh seeds after having been sifted and cleaned from dust stones, and all extraneous matters, and slightly crushed between two rollers, freed by hand from husk and coloured grains, are enclosed in clean gunny. They then receive a slight pressure in an oblong mould which gives a uniform shape and density to the packets of seed. The "Bricks" as they are technically called, are then placed alternately with plates of sheet iron in water in the ordinary screw or hydraulic press. The oil thus procured is received in clean tin pans, and water, in the proportion of a pint to a gallon of oil, being added, the whole is boiled until the water has evaporated, the mucilage will be found to have subsided and encrusted the bottom of the pan, whilst the albumen solidified by the heat, forms a white layer between the oil and the water. Great care must be taken in removing the pan from the fire, the instant the whole of the water has evaporated, which may be known by the bubbles having ceased, for if allowed to remain longer the oil which has hitherto been of the temperature of boiling water or 212° *sudden-*

ly rises to that of oil or nearly 600° thereby heightening the color and communicating an empyreumatic taste and odour. The oil is then filtered through blanket, flannel, or American drill, and put into cans for exportation. It is usually of a light straw colour, sometimes approaching to a greenish tinge. The cleaned seeds yield from 47 to 50 per cent of oil worth in England from 4*d.* to 5*d.* per lb. The following is the result of experiments made at Madras and Calcutta to ascertain the per-centage of oil in the Castor seed. (January 27th, 1853.)

Calcutta.—1400 lbs of seed yield kernels and raw oil as follows :—

	Kernels.	Oil.
1st Sort.....	632lbs.....	324 lbs.
2nd Sort.....	184lbs.....	87½lbs.
3rd Sort.....	164lbs.....	76½lbs.

Making a total of 980lbs. of kernels and 488lbs. of raw oil from 1,800lbs. of seed.

Madras.—1400 lbs. of seed yield raw oil as follows :—

1st Sort.....	...318 lbs.	of oil.
2nd Sort	88 lbs.	do.
3rd Sort.....	74 lbs.	do.

Making a total of 480 lbs. of oil from 1400 lbs. of seed.

The Cost of the Madras oil is as follows :

1400 lbs. of seed at Rs. 3 3 per bag of 164lbs.....	27	3	4
Husking and selecting kernels and cooly hire	3	11	9
Crushing, moulding, pressing and boiling	2	7	1
Filtering and sundries.....	2	8	0
Overseer's pay, Godown Rent, &c. &c.	1	6	2
300 empty Quart bottles, corks &c. 34	4	8	
Cleaning and Packing charges.....	4	8	0
	Rs. 76	1	0

Or an average of Annas $4\frac{17}{300}$ per quart of First, Second and Third sort oil=4d per. lb.

Uses.—This oil is chiefly used as a mild Purgative. Soap of good quality may be made of it, but the cost and disagreeable smell which it communicates, preclude its general use.

Exports.—Average for the last 4 years 1849-50 to 1852-53, 11,325 galls. per annum. At the Madras Exhibition of 1851, the samples of this oil exhibited by Mr. Gay, Madras, Mr. Kohlhoff, Tanjore, and Monsieur Godefroy of Pondicherry were particularly fine. Mr. Gay's specimen was the clearest, and most limpid, and devoid of any offensive smell. These qualities however do not arise from any superiority of the seed, or care in extraction, but from repeated decolorization with animal charcoal which in the opinion of many eminent Medical men, considerably detracts from its strength and efficacy. Appavoo Pillay of Tinnevelly, the Nellore Local Committee, and Lieut. Hawkes also exhibited excellent specimens. When manufactured in the ordinary Native mill, this oil is sometimes used by the richer classes in Lamps.

Castor oil (extracted hot). This differs from the preceding only in the mode of preparation—The seeds are boiled for two hours in water, dried for three days in the sun, freed from the shells, pounded and then boiled in fresh water, until the whole of the oil has risen to the surface. Five seers of the seeds or $3\frac{1}{8}$ lb. should by this process yield a quart of oil. This is the sort generally used in medicine by native practitioners, it is straw colored, and free from any unpleasant taste or smell.—*M. E. J. R.*

(7166) RICINUS COMMUNIS. Castor or Lamp oil plant, Fructibus majoribus.

Vullak ennai, TAM. | Chirach ka tael, HIND.
Ped amidum, TEL.

This oil which is obtained from the large seeded variety of the "Ricinus communis" is sometimes drawn cold, and a straw-colored specimen scarcely distinguishable in quality from the oil of the small seeded variety was shown by Lieut. Hawkes. It is however more usually extracted by heat, and forms the common "Lamp oil" of the bazar.

Mode of preparation—The seeds having been partially roasted over a charcoal fire, both to coagulate the albumen and to liquify the oil, are then pounded and boiled in water until the oil rises to the surface. The roasting process, however gives it a deeper red colour and an empyreumatic odour.

Price.—The price of this oil varies in different parts of the country from Rs. 1 10 0 to Rs. 3 13 6 per maund of 25lbs. The average of nineteen large stations, in all parts of the Madras Presidency for the Quarter ending 31st October 1854 was Rs. 2 3 6 per maund.

Uses.—Chiefly for lamps.

Exports.—Average of the last six years Galls. 27,561 per annum.—*M. E. J. R.* See CASTOR OIL.

(7167) RICINUS. A wild species from Canara. Is burnt in lamps.

(7168) RICINUS DIOCOCA.

Tawthedinbin, BURM.

Scarce and found only on the banks of streams in the Pegu and Tounghoo districts. Very tall large timber; wood, red, adapted to cabinet making.—*McClelland.*

(7169) RICINUS MAPPA, 816.

(7170) RIVEA. Of this genus, Wight gives Rivea cuneata, 890; cymosa, 839; hirsuta, 891; ornata, 1356; pomacea, 888; speciosa, 851; and tiliœfolia, 1358.

(7171) RIVEA FRAGRANS.

Boodthee-keeray, TAM.

A beautiful variety of the convolvulus tribe; flowers transparent white, opening at sunset and perfuming the air with a very pleasant odour; leaves used as greens; found in hedges, called the clove scented creeper by Europeans.—*Jaffrey.*

(7172) ROCCELLA, a genus of Plants belonging to the family of Lichens. The species are used in dyeing, and are popularly called Orchil, or Archil. This name is derived from the Oricello of the Italians or the Spanish Orchella. It is often corrupted in commerce into Rochilla-Weed. Several species of Lichens are employed for the same purpose, which are distinguished according to the country whence they are imported, and also by manufacturers into weed and moss, the former name being applied to the Filiform Lichens of botanists belonging to the genus *Roccella* to be treated of here, whilst the terms Moss and Rock-Moss are applied to the Crustaceous Lichens belonging to the genus *Lecanora*, which include the Cudbere and Parell of dyers. [PARELLA.] The character of the genus *Roccella* is as follows:—Thallus coriacco-cartillaginous rounded or plane, branched or lacineated; apothecia orbicular, adgate with the thallus; the disc coloured, plano-convex, with a border at length thickened and elevated, formed of the thallus, and covering a sublentiform black compact pulverulent powder, concealed from within the substance of the thallus.—*Eng. Cyc.*

Various lichens, and *Roccella tinctoria*, from Tenasserim and other parts of India, have been introduced into Britain by the East India Company. In the Admiralty instructions given to Capt. Sir James C. Ross, on his Antarctic voyage, a few years ago, his attention was specially called to the search and enquiry for substitutes for the *Roccella*, which is now becoming scarce. A prize medal was awarded, in 1851, to an exhibitor from the Elbe for specimens of the weed, and an extract of red and violet orchil. Specimens of varieties of the lichens used in the manufacture of cudbear orchil and litmus, and of the substance obtained, were also shown in the British department, for which were awarded prize medals.—*Simmonds.*

(7173) ROCCELLA FUCIFORMIS, the Flat-Leaved Orchil. Thallus flat, branched, nearly upright grayish-white, bearing powdery warts; apothecia horny, bordered. Both kinds are found on maritime rocks, or on dry stone walls exposed to the influence of the sea-breeze, as well on the coast of England as on the shores of the Mediterranean and the East Indies. The more arid the situation, the better is the quality of the lichens. The presence of the colouring matter is ascertained by steeping the weed broken up in small pieces in diluted solution of ammonia, in a bottle half filled with liquid, which should be kept corked, but frequently opened in a temperature not exceeding 150° Fahr.

(7174) ROCCELLA TINCTORIA. Dyer's Roccella, or Orchil. Thallus suffrutieose, rounded, branched, somewhat erect, grayish-brown, bearing powdery warts; apothecia flat and horny, with a scarcely prominent border. A practical writer describes "the good kind as having a mealy white powder on its surface towards the centre; the under surface is of a gray colour; and is not hairy; if wetted, it does not turn of an orange colour: its edges are flat and thin."

(7175) ROCK OIL. PETROLEUM. The following account of the collection of Petroleum in the Island of Cheduba is given by Captain Halstead. Petroleum is found on the Island and might be extensively produced. Two wells sufficiently near each other to afford the conclusion of their possessing one common source, exist in the Kraerore circle, yielding annually about 60 pots each. A third is found in the "Mromee" circle, but it has been destroyed by fire and yields nothing, being the property, at present, of no one in particular, the soil around it, is however, full of the oil. The fourth and most extensive is in the Frangroa circle and yields near 200 pots in the year. The method of collecting it is simple: the earth is turned up to a depth of two feet, and a bank of soil raised round a square of about 20 yards, is distributed so as to form it during the rains into a shallow pond of about the above depth. The surface of this pond is in a constant state of ebullition from the escape of gas with which comes up the Petroleum. It collects on the surface in three different forms; a geen fluid oil first spreads itself over the spot where the gas is bubbling up. As it extends, its edges exhibit a brown curdled substance resembling half congealed dripping, and amongst this, as it becomes thicker is seen gathering in spots a dark brown substance of the color and consistency of molasses. This latter is used to preserve wood, to saturate paper for umbrellas, and is sometimes burned. But the fluid of a green color, is that mostly used to supply lamps. The curdled substance is used with the dark in the coarser purposes to which it is applied. This is the least valuable and sells at 5 pots for a rupee. The other two at 3 pots for 2 rupees. A bamboo is used to skim the surface of the ponds, and bring the substance to the bank, it is scooped up with a cocoanut shell and put into the pot. It floats so lightly on the water that this process is quickly and effectually performed. The break of the day is the time chosen for the operation as from the cooler temperature, it is then of harder consistence on the water and easier and cleaner skimmed. In the heat of the day it becomes so fluid as to make it difficult to collect without a large proportion of the water. In the months of March and April the pond gradually dries up, and the oil can then be no longer collected from out the soil. The pond is then dug, and the whole soil in it as much disturbed as possible: on this operation depends the quantity to be yielded during the next season, and the deeper it is dug, the larger will be the produce; while on the other hand, if it be neglected, which is most commonly the case, the quantity of oil to be collected will be very materially diminished. A

sort of superstitious fear is attached to these ponds, and on no account would a native dip his foot in its water, though he will not hesitate to dig the soil when dry, nor to handle its produce, to which no sort of dileterious property is attributed. The state of ebullition without apparent heat may occasion this feeling among them. The ponds are surrounded by a rough hedge of stout sticks, to preserve them from the intrusion of buffaloe or deer. Insects were seen in them. I had no means of collecting any of the escaping gas, which I should otherwise have done, but no heat perceptable at the surface is employed for its extensive development, the thermometer where the greatest ebullition was going forward showing but two degrees more than the atmosphere viz 74. No doubt this mineral product might with case, and little expense, be increased to a very larg amount, and the oil has yet perhaps to be bette known and better appreciated than now whe its value will in all probability be much increased —*Rohde, M,S.S.* See ASPHALTE. NAPHTHA and PETROLEUM.

(7176) RODENTIA, an order of Animal belonging to the class *Mammalia*, embracing th Rats and Mice, Hares, Rabbits, Guinea-Pigs and other well-known animals. The following i Mr. Waterhouse's arrangement of these ani mals :—

		Europe and North Asia.	North America.	Africa	India and Islands	South America and West India Islands
MURINA	SCIURIDÆ	5. Sciurus. 1. Pteromys. 1. Tamias. 3. Spermophilus. 2. Arctomys.	20. Sciurus. 3. Pteromys. 5. Tamias. 10. Spermophilus 8. Arctomys. 1. Aplodontia.	5. Sciurus. 3. Xerus. 2. Graphiurus.	25. Sciurus. 9. Pteromys.	6. Sciurus.
	MURIDÆ	3. Myoxus. 8. Dipus. 1. Mus. 6. Cricetus.	2. Meriones. 6 {Mus. Hesperomys 1 Sigmodon. 2. Neotoma.	3. Myoxus. 4 Dipus. 10. Mus 2. Dendromys. 6. Gerbillus. 1 Psammomys. 3. Euryotis.	12. Mus 2 Gerbillus 1 Phleomys. 2. Rhizomys.	30 {Mus. Hesperomys 3. Reithrodon.

These animals have two great incisor teeth in each jaw, separated from the molars by a wide space, with which they could hardly seize a living prey, or rend flesh; they could not even cut aliments, but they might serve for reducing them by continued labour into fine molecules—in word, for gnawing them; whence the term Rodents, or Gnawers, applied to this or

der. With these weapons they attack the hardest vegetable productions, and frequently feed on wood and bark.

The form of the body of the Rodents is in general such that their hinder parts exceed their anterior ones, so that they leap rather than walk; this disposition in some of them is as excessive as in the Kangaroos.—*Eng. Cyc.*

(7177) ROE: *Fish roes*, *Red Fish*, and *Sardines*, are Malay condiments and the species used in the preparation, are *Alausa toli*, (*Ikan truboh*,) *Engraulis Brownii*, (*Bunga ayer or badah*,) *Dussumieria acuta* (*Tamban-bulat*) and *Clupeonia perforata*,(*Tamban-nepes or batuh*)--*Cantor.*

(7178) ROHEPITTA, the gall of fishes.

(7179) ROHUN BARK. ROHUN-KE-CHILKEE. Rohunæ Cortex. Bark of Soymida febrifuga, is not spotted with rusty patches, and the inside is dark reddish brown, nitric acid does not stain it of a bright scarlet. These tests distinguish it from the poisonous bark of the nux vomica tree (Kuchila,) which is commonly sold for it in the bazars of Bengal.—*Beng. Phar.*

(7180) RONDELETIA, a genus of Plants belonging to the natural order *Rubiaceæ*, named after Rondelet, a French botanist of the 16th century. It is characterised by having a calyx with a subglobular tube. Corolla superior, funnel-shaped, ventricose at the throat; segments 4-5, ovate-obtuse, spreading; anthers 4-5, sessile within the corolla; ovary-2-celled; style filiform; stigma bifid; capsule round, crowned with the limb of the calyx. Seeds minute, numerous, or few when abortive. The genus, as formerly constituted, included many shrubby trees which occur in India (Roxb., 'Fl. Indica'), but these have been referred by modern botanists to *Adenosacme*, *Greenia*, and *Wendlandia*. The present genus *Rondeletia* occurs chiefly in America and the West Indies.—*Eng. Cyc.*

(7181) RONDELETIA TINCTORIA.

Tomayoke, BURM.; Tooralodh, HIND.

Small timber, adapted, from the fineness of the grain and elegance of colour, for ornamental work: wood dark-brown.—*McClelland.* The tree grows also in the Kotah and Mewar jungles the bark is used in dyeing red.—*Genl. Med. Top. p.* 182.

(7182) ROOSA OIL: GRASS OIL, ANDROPOGON CALAMUS AROMATICUS.

Roosa Teil, GUZ. HIND.

A valuable oil, obtained from a grass a native of the low hills at the base of the Himalayas; also found at Asseerghur, Malwa, and Guzerat. It is chiefly imported into Bombay from Surat, and is re-exported in considerable quantities to England, China, and the Arabian and Persian Gulfs. It is highly esteemed by the natives of India as a cure for rheumatism, colds, and as an internal stimulant. *Faulkner.* This oil differs but little either in appearance or quality from the Lemon Grass Oil and is used for the same purposes. Roosa grass oil, the produce of "*Andropogon Calamus aromaticus*" was exhibited from the Nizam's territories by Dr. Riddell at the Madras Exhibition of 1855, but is found to be a good substitute for the more expensive Cajeput oil, and is a useful rubefacient. —*M. E. J. R.*

(7183) ROPE.

Doodah, GUZ.; Russee, HIND.

Consists of hemp, coir, cotton, straw, and other fibrous materials, spun into thick yarn, of which several strings are twisted together by means of a wheel. All the different kinds of this manufacture, from a fishing line or whip-cord, to a cable, go by the general name of cordage.—*Faulkner.* There is not in Southern Asia any large Rope walk, but for the materials for Rope making we refer to the articles FIBRES: CORDAGE.

(7184) ROSE ATTAR AND ROSE WATER. In India the perfumed oils are obtained in the following manner: The layers of the jasmine, or other flowers, four inches thick and two inches square, are laid on the ground and covered with layers of sesamum or any other oil yielding seed. These are laid about the same thickness as the flowers, over which a second layer of flowers like the first is placed. The seed is wetted with water, and the whole mass covered with a sheet, held down at the end and sides by weights, and allowed to remain for eighteen hours in this form. It is now fit for the mill, unless the perfume is desired to be very strong, when the faded flowers are removed and fresh ones put in their place. The seed thus impregnated is ground in the usual way in the mill and the oil expressed, having the scent of the flower. At Ghazipoor the jasmine and bela are chiefly employed; the oil is kept in the dubbers, and sold for about 4s. a seer. The newest oils afford the finest perfume. In Europe a fixed oil, usually that of the bean or moringa nut, is employed. Cotton is soaked in this, and laid over layers of flowers, the oil being squeezed out so soon as impregnated with perfume. Dr. Jackson thus describes the culture and manufacture:—

(7185) *Roses, Cultivation of,*—Around the station of Ghazipoor, there are about 300 biggahs (or about 150 acres) of ground laid out in small detached fields as rose gardens, most carefully protected on all sides by high mud walls and prickly pear fences, to keep out the cattle. These lands, which belong to Zemindars, are planted with rose trees, and are annually let out at so much per biggah for the ground, and so much additional for the rose plants—generally five rupees per biggah and twenty-five rupees for the rose trees, of which there are 1,000 in each biggah. The additional expense for cultivation would be about eight Rupees eight annas; so that for thirty-eight

rupees eight annas you have for the season one biggah of 1,000 rose trees. If the season be good, this biggah of 1,000 rose trees should yield one lac of roses. Purchases for roses are always made at so much per lac. The price of course varies according to the year, and will average from 40 to 70 rupees.

Manufacture of rose-water.—The rose trees come into flower at the beginning of March, and continue so through April. Early in the morning the flowers are plucked by numbers of men, women, and children, and are conveyed in large bags to the several contracting parties for distillation. The cultivators themselves very rarely manufacture. The native apparatus for distilling the rose-water is of the simplest construction; it consists of a large copper or iron boiler well tinned, capable of holding from eight to twelve gallons, having a large body with a rather narrow neck, and a mouth about eight inches in diameter; on the top of this is fixed an old degh-chee, or cooking vessel, with a hole in the centre to receive the tube or worm. This tube is composed of two pieces of bamboo, fastened at an acute angle, and it is covered the whole length with a strong binding of corded string, over which is a luting of earth to prevent the vapour from escaping. The small end, about two feet long, is fixed into the hole in the centre of the head, where it is well luted with flower and water. The lower arm or end of the tube is carried down into a long-necked vessel or receiver, called a bhulka. This is placed in a pot of water, which, as it gets hot, is changed The head of the still is luted on to the body, and the long arm of the tube in the bhulka is also well provided with a cushion of cloth, so as to keep in all vapour. The boiler is let into an earthen furnace, and the whole is ready for operation. There is such a variety of rose water manufactured in the bazar, and so much that bears the name, which is nothing more than a mixture of sandal oil, that it is impossible to lay down the plan which is adopted. The best rose-water, however, in the bazar, may be computed as bearing the proportion of one thousand roses to a seer of water; this, perhaps, may be considered as the best procurable. From one thousand roses most generally a seer and a half of rose-water is distilled, and perhaps from this even the attar has been removed. The boiler of the still will hold from eight to twelve or sixteen thousand roses. On eight thousand roses from ten to eleven seers of water will be placed, and eight seers of rose-water will be distilled. This after distillation is placed in a carboy of glass, and is exposed to the sun for several days to become pucka (ripe); it is then stopped with cotton, and has a covering of moist clay put over it: this becoming hard, effectually prevents the scent from escaping. The price of this will be from

twelve to sixteen rupees. This is the best that can be procured.

(7186) *Roses, Attar of.*—To procure the attar, the roses are put into the still, and the water passes over gradually, as in the case of the rose-water process; after the whole has come over, the rose-water is placed in a large metal basin, which is covered with wetted muslin, tied over to prevent insects or dust getting into it; this vessel is let into the ground about two feet, which has been previously wetted with water, and it is allowed to remain quiet during the whole night. The attar is always made at the beginning of the season, when the nights are cool; in the morning the little film of attar which is formed upon the surface of the rose-water during the night is removed by means of a feather, and it is then carefully placed in a small phial; and, day after day, as the collection is made, it is placed for a short period in the sun, and after a sufficient quantity has been procured, it is poured off clear, and of the color of amber, into small phials. Pure attar, when it has been removed only three or four days, has a pale greenish hue; by keeping it loses this, and in a few weeks' time it becomes of a pale yellow. The first few days distillation does not produce such fine attar as comes off afterwards, in consequence of the dust or little particles of dirt in the still and the tube being mixed with it. This is readily separated, from its sinking to the bottom of the attar, which melts at a temperature of 84 degrees. From one lac of roses it is generally calculated that 180 grains, or one tolah, of attar can be procured; more than this can be obtained if the roses are full sized, and the nights cold to allow of the congelation. The attar purchased in the bazar is generally adulterated, mixed with sandal oil or sweet oil; not even the richest native will give the price at which the purest attar alone can be obtained, and the purest attar that is made is sold only to Europeans. During the past year it has been selling from 80 to 90 rupees the tolah; the year before it might have been purchased for 50 rupees.

(7187) *General Remarks.* Native stills are let out at so much per day or week, and it frequently occurs that the residents prepare some rose-water for their own use as a present to their friends, to secure their being provided with that which is the best. The natives never remove the calices of the rose-flowers, but place the whole into the still as it comes from the garden. The best plan appears to be to have these removed, as by this means the rose-water may be preserved a longer time, and is not spoiled by the acid smell occasionally met with in the native rose-water. It is usual to calculate 100 bottles to one lac of roses. The rose-water should always be twice distilled; over ten thousand roses water may be put to allow of sixteen or twenty bottles coming out; the following day these twenty bottles are placed over eight thou-

sand more roses; and about eighteen bottles of rose-water are distilled. This may be considered the best to be met with. The attar is so much lighter than the rose-water, that, previous to use, it is better to expose the rose-water to the sun for a few days, to allow of its being well mixed; and rose-water that has been kept six months is always better than that which has recently been made. At the commencement of the rose season, people from all parts come to make their purchases, and very large quantities are prepared and sold. There are about thirty-six places in the city of Ghazeepore where rose-water is distilled. These people generally put a large quantity of sandal oil into the receiver, the oil is afterwards carefully removed and sold as sandal attar, and the water put into carboys and disposed of as rose-water. At the time of sale a few drops of sandal oil are placed on the neck of the carboy to give it fresh scent, and to many of the natives it appears perfectly immaterial whether the scent arises solely from the sandal oil or from the roses. Large quantities of sandal oil are every year brought up from the south and expended in this way.

The chief use the natives appear to make of the rose water, or the sandal attar as they term it, is at the period of their festivals and weddings. It is then distributed largely to the guests as they arrive, and sprinkled with profusion in the apartments. A large quantity of rose water is sold at Benares, and many of the native Rajahs send over to Ghazipoor for its purchase. Most of the rose water, as soon as distilled, is taken away, and after six months from the termination of the manufacture there are not more than four or five places where it is to be met with. I should consider that the value of the roses sold for the manufacture of rose water may be estimated at 15,000 to 20,000 rupees a year; and from the usual price asked for the rose water, and for which it is sold, I should consider there is a profit of 40,000 rupees. The natives are very fond of using the rose water as medicine, or as a vehicle for other mixtures, and they consume a good deal of the petals for the conserve of roses, or goolcond as they call it.—*O'Shaughnessy, p.* 326. In addition to the above, we observe the following in Simmonds. The roses of Ghazipoor on the river Ganges, are cultivated in enormous fields of hundreds of acres. The delightful odor from these fields can be scented at seven miles distance on the river. The valuable article of commerce known as attar of roses is made here in the following manner:—On 40 pounds of roses are poured 60 pounds of water, and they are then distilled over a slow fire, and 30 pounds of rose water obtained. This rose water is then poured over 40 pounds of fresh roses, and from that is distilled at most 20 pounds of rose water; this is then exposed to the cold night air, and in the morning a small quantity of oil is found on the surface. From 80 pounds of roses, about 200,000, at the utmost an ounce and a-half of oil is obtained; and even at Ghazipoor it costs 40 rupees (4*l.*) an ounce. Five guineas have been often paid for one ounce of attar of roses. The most approved mode of ascertaining its quality is to drop it on a piece of paper; its strength is ascertained by the quickness with which it evaporates, and its worth by its leaving no stains on the paper. The best otto is manufactured at Constantinople.—*Simmonds.*

(7188) ROSA: *Species.* CHINA YELLOW ROSE. On this and another rose, Fortune says, the gardens of the mandarins were extremely gay, particularly during the early months of the year, and, what was of more importance to me, contained a number of new plants of great beauty and interest. On entering one of the gardens on a fine morning in May, I was struck with a mass of yellow flowers which completely covered a distant part of the wall. The colour was not a common yellow, but had something of buff in it which gave the flowers a striking and uncommon appearance. I immediately ran up to the place and, to my surprise and delight, found that it was a most beautiful new double yellow climbing rose. I have no doubt, from what I afterwards learned, that this rose is from the more northern districts of the empire, and will prove perfectly hardy in Europe. Another rose, which the Chinese call the "five coloured" was also found in one of these gardens at this time. It belongs to the section commonly called China roses in Great Britain, but grows in a very strange and beautiful manner. Sometimes it produces self colored blooms being either red or French white and frequently having flowers of both on one plant at the same time while at other times the flowers are striped with the two colours. This will also be as hardy as our common China Rose. Glycine sinensis is often grown on a flat trellis in front of the summer house or forms a kind of portico, which affords a pleasing shade. Entwined with one of these trees, I found another variety, having very long racemes of pure white flowers, which contrasted well with the light blue of the other. I obtained permission from the old Chinese gentleman to whom it belonged (my old friend Dr. Chang) to make some layers of this fine plant, and I am happy to say that one of these is now alive in the garden at Chiswick.—*Fortune's Wanderings, page* 311.

(7189) ROSE. Rosa.

Wurd, Arab.	Gul, Guz.
Gul, Beng.	Gul, Gul-ab-ka-phool, H.
Hoa-houng-tan, Coch-chin.	Rosa, It.
Mei-kwe hwa, Chin.	Mawar, Mal.
Rose a cent feuilles, Fr.	Gul, Pers.
Blassen-rose, Ger.	Gulaba-poo, Tam.

Rosa (from the Latin *Rosa*, through the medium of the French Rose; the Latin *Rosa* and the Greek *Ῥόδον* are evidently the same)

the name of the most universally admired and cultivated genus of plants, forming the type of the natural order *Rosaceæ*. The Rose was known in early times, and was as great a favourite among the nations of antiquity as it is in modern times. The Rose is found generally in almost every country of the northern hemisphere, both in the Old and New World; from Sweden to the north of Africa; from Kamtchatka to Bengal, and from Hudson's Bay to the mountains of Mexico. It is not found in South America or in Australia. All the species are included between 70° & 19° N. lat. It is found more generally on dry and free soils than on those which are wet and tenacious. In the north of Europe it occurs with single flowers, but in Italy, Greece, and Spain more frequently double. The characters of the genus *Rosa* are—calyx 5-parted, tube fleshy, urceolate; petals five; stamens numerous, attached to the calyx and corolla; ovaries attached to the inner surface of the tube of the calyx; style long, stigma projecting beyond the mouth of the calyx; achenia numerous, hard. The species are mostly shrubs with alternate pinnate leaves and beautiful odoriferous flowers. There are few better marked genera amongst plants than this, but as of all plants it has been the greatest favourite, and thus surrounded by the greatest variety of external influences, its species and varieties are the most difficult to distinguish.—*Eng. Cyc.* Regarding the cultivation, in India, of this favorite plant, bearing such a variety of coloured flowers, —from the deep red to the pale yellow and white, with all their intermediate shades—we may point out that the easiest mode of propagation is by layers at almost all seasons, or by cuttings at the commencement of the rains. The Persian varieties, red and white, require to have their roots opened, and the plants cut during the early part of the cold season, after which they must be watered well every second or third day. The roots must then be covered up with manure, when they will throw out flowers, which are generally used for rose water. The Rose Edward, which blossoms great part of the year, requires pruning about a month after it ceases to blossom, and should be allowed to rest a short time without watering, when a fresh supply of water and manure round the roots will cause it to bear flowering shoots immediately. This rose, and the Egyptian, are amongst the few that give seed-hips being perfectly formed on both.—*Riddell.*

Dr. Lindley, in his 'Rosarum Monographia,' arranges the species under eleven divisions, the first of which, including but one species, has since been made into the genus *Lowea*. We shall here give the remaining divisions, and point out the species which, on account of their ornamental flowers or uses, are most frequently cultivated.

1. *Feroces*, with branches permanently tomentose and naked fruit. They are generally low shrubs, remarkable for thick hoary branches clothed with numerous prickles, and hence their name. There are only three species belonging to this division, of which *Rosa ferox*, the Hedgehog-Rose, is most common.

2. *Bracteatæ*.—The species of this division have not only their branches, but also their fruit clothed with a persistent tomentum. They have mostly bright-green leaves, and their organs of fructification are in the highest state of development of any of the genus. They belong to the class of evergreen roses. *R. bracteata*, the Macartney Rose, is a native of China, and was introduced into Great Britain by Lord Macartney. It has upright branches, 5-9-leaflets, stout prickles, with large white terminal solitary flowers, and large globose orange red fruit. It is a handsome plant, flowering abundantly late in the season. *R. microphylla*. Small-Leaved Rose, resembles *R. bracteata*, but differs in being smaller, and having prickly fruit and ovate-obtuse leaves.

3. *Cinnamomeæ*, distinguished by their long lanceolate leaflets, without glands, bracteated flowers, and delicate but little thickened. The shoots are either with or without setæ. There are several species in this division, but comparatively few are known out of the herbarium. *R. lucida*, the Right-Leaved Rose; *R. laxa*, Loose or Spreading Carolina Rose; and *R. Carolina*, the True Carolina Rose, belong to this division.

4. *Pimpinellifoliæ*.—Branches either crowded with nearly equal prickles or unarmed; leaflets ovate or oblong: bracts absent; sepals connivent and persistent. Although this division approaches the last in artificial characters; it is essentially different in habit. *R. spinosissima*, the Scotch Rose, is a dwarf, compact, green bush, with creeping roots; it has unequal prickles, flat, glabrous, simple serrated leaflets, and small, solitary, white, or bluish-coloured flowers. It is found native in the mountainous districts and sea-coasts of all Europe, and also in the Caucasus. It was the only rose found by Sir W. Hooker in Iceland. A great number of varieties are found in the gardens of Britain, produced from the wild plant found in the North of England and Scotland, *R. sulphurea*, the Double-Yellow Rose, and *R. alpina*, the Boursalt Rose, are also examples.

5. *Centifoliæ*, clothed with bristles and prickles; flowers bracteate; leaflets oblong or ovate, rugous, disc thickened, closing the throat; sepals compound. This division comprehends those species which have ever been most interesting to the florist, as also probably those that were earliest known. Although the garden varieties of this division would probably amount to several hundred, there are only three species.—*Eng. Cyc.*

(7190) ROSA CANINA, the Dog-Rose, is one of the most common species of the division in this country, and from its varying characters

has given origin to a great number of names supposed to represent species. This is the species used for making conserve of roses.

9. *Systylæ.*—Styles cohering in an elongated column; stipules adnate. The habit of the plants of this division is nearly the same as that of the last. *R. arvensis*, the Field or White Dog-Rose, belongs to this group. It is a very common plant in many parts of England, adorning the hedges with its elegant snowy blossoms. It has cord-like shoots, unequal falcated prickles, leaflets glaucous beneath; diverging stipules, and ovate crimson fruit. The varieties of this and allied species, as *R. multiflora* and *R. sempervirens*, produce the climbing roses of the garden, of which there a great number now to be had.

(7191) ROSA CENTIFOLIA. (HUNDRED-LEAVED ROSE.

Goolab Sudburg. PERS. | Wurd, ARAB.

A native of Syria, cultivated in Europe. The odour of this species is but partially destroyed by desiccation, and according to M. Chereau is remarkably augmented by iodine. It is less astringent than the Provence rose, and more laxative. It furnishes essential oil in small quantities, and is much employed for distillation of rose water, and in the preparation of the essential oil, or *Utr.* The petals of this as well as of the R. gallica are preserved with salt by the European apothecaries for the preparation of the distilled water.—*O'Shaughnessy.* *R. centifolia*, the Hundred-Leaved Cabbage, or Provence Rose, is known by its large unequal prickles, glandulous leaflets, pendulous flowers, and oblong fruit. This rose has been said to be a native of France, but this is doubtful. It has been found wild in thickets on the eastern side of the Caucasus. It is the same plant as the *R. provincialis* of Miller. A botanical variety of this species, the *R. centifolia muscosa*, is the parent of the beautiful family of moss-roses.—*Eng. Cyc.*

(7192) ROSA DAMASCENA, the Damask Rose, has unequal prickles; the larger ones falcate, sepals reflexed, fruit elongated. This plant is supposed to have been originally brought from Damascus, and to be a native of Syria. It is much cultivated in gardens, and has not fewer varieties than the two last.

6. *Villosæ.*—Root-shoots erect; prickles nearly straight; leaflets ovate or oblong, with diverging serratures, sepals persistent, connivent; disc thickened, closing the fauces. The best known species of this division is the *R. alba*, White Rose; it has rugose glaucous leaves, with simple serratures and acicular unequal prickles, by which it may be distinguished from both R. *tomentosa* and *R. canina*, with which it is liable to be confounded. It is a native of Piedmont, Cochin-China, Denmark, France, and Saxony. Its flowers are very large, exhaling a delicious fragrance. *R. Hibernica*, the Irish Rose, belongs to this division, and is interesting to the botanists as being entirely confined to Ireland.

7. *Rubiginosæ.*—Unequal and sometimes bristly prickles, ovate or oblong leaflets, with glands and diverging serratures, persistent sepals, thickened disc, and arched root shoots. To this division belongs the *R. rubiginosæ*, Eglantine, or Sweet Briar. It is common in Britain in bushy places on a dry gravelly soil. *R. lutea*, the Austrian Briar, is nearly allied to the latter.

8. *Caninæ.*—With equal hooked prickles; oval eglandulose leaflets, with connivent serratures, deciduous sepals, and thickened disc closing the throat. To this division belong many of the varieties called Autumnal or Perpetual Roses, on account of their blooming late in the season and continuing in flower a long time. Of the roses in this group that have afforded varieties for the garden, the *R. Indica*, Chinese Rose, stands first. There is a hybrid variety between this species and the *R. odorata*, which is well known in gardens under the name of *R. Indica odorata*, Tea-Scented China Rose. This rose is the parent of a great number of sorts in gardens. The Bourbon Rose (*R. Bourboniana*) is a natural hybrid between *R. Indica* and a variety called Red Four-Seasons. This hybrid was found amongst a number of the latter plants in a hedge in the Isle of Bourbon. It was brought to Paris, and has since produced many beautiful varieties. The Noisette Rose was grown from seeds produced from *R. moschata* impregnated with *R. Indica*. It was first reared in America.

(7193) ROSA GALLICA (FRENCH, OR PROVENCE RED ROSE.)

Gul. HIND.

This is a native of Persia, the petals contain tannic and gallic acid, essential oil, oxide of iron, and other unimportant principles. The petals are gathered before becoming quite ripe, they are deprived of the calyx and central attachments, and dried before the sun or in a stove. When dried they are sifted in order to separate the stamina and pistil. They are then gently compressed and kept in a dry place. From a variety of this species, the cabbage rose, a very fragrant distilled water is prepared in England. —*O'Shaughnessy, page* 326. *R. Gallica*, the French Rose, has equal small prickles, erect flowers, ovate sepals, and globose fruit. It is found wild about Montalbanum, Walzenberg, and Geneva, also in Austria, Piedmont, and the Caucasus. This is supposed to be the species to which Pliny refers ('Hist. Nat.,' xxi. 18, 25, 72. 73). *R. pumila* of Jacquin is a variety of this species. Hundreds of varieties of this rose are found cultivated in gardens. A great number of varieties of roses found in gardens are hybrids between *R. Gallica* and *R. centifolia.* They mostly combine the long graceful shoots of the last with the rich crimson hues of the first. Hybrids are also produced

between *R. Gallica* and *R. Indica*, but differ from the last in not being perpetual. They have a pleasing glossy sub-evergreen foliage.—*Eng. Cyc.*

(7194) ROSA LAWRANCEANA, the Minature or Lawrance Rose, named after Miss Lawrance, who published a collection of drawings of roses, belongs to this division. It was first brought from China, and is probably only a dwarf variety of *R. Indica* or *R. semperflorens*. which it closely resembles in structure.—*Eng. Cyc.*

(7195) ROSA MACROPHYLLA. The great red rose is one of the most beautiful Himalayan plants, whose single flowers are as large as the palm of the hand.—*Hooker Him. Jour. Vol.* II, *p.* 43.

(7196) ROSA MOSCHATA, the Musk-Rose, is one of the oldest inhabitants of our gardens. It is found native in the North of Africa, and in the temperate and warm provinces of Spain.

10. *Banksianæ*.—Nearly free subulate stipules, usually deciduous; ternate shining leaflets and climbing stems. This is the last division of the species of roses. The most remarkable species in this group is the *R. Banksiæ*, Banksian Rose, named after Lady Banks. It is a native of China, and has very numerous double sweet-scented nodding flowers, which are arranged in umbel-like corymbs. The roses are used in the arts for obtaining their delicious perfume, which is called Attar of Roses. The petals are also used in medicine.—*Eng. Cyc.*

(7197) ROSA RUBIGINOSA. SWEET-BRIAR. Native name, gul nusreen. This species of rose which was once scarce in the Deccan is now to be met with in many gardens—it sometimes blossoms, if budded on the Persian rose stock. The general mode of propagation is by layers, but a much quicker and easier method is to bud it on the stock of a rose.—*Riddell.* Tenasserim residences are often filled with sweet odours from the grateful eglantine, or sweet briar, but the plant is kept alive with difficulty when exposed to the southwest monsoon.—*Mason.*

(7198) ROSA SERICEA. Is an erect white flowered rose, and the only species occurring in Southern Sikkim. It is very abundant: its numerous inodorous flowers are pendent, apparent as a protection from the rain, and it is remarkable as being the only species having four petals, instead of five.—*Hooker, Him. Jour. Vol.* I, *p.* 168.

(7199) ROSACEÆ, a natural order of Polypetalous Exogenous Plants, with 4-5-lobed calyx; 4 or 5 regular petals; indefinite perigynous stamens; exalbuminous seed; and alternate stipulate leaves. The plants of this order are allied to *Chrysobalanaceæ*, from which they may be distinguished by their styles proceeding from the side of the ovarium near the apex, and not from the base, and by their regular petals and stamens. They are distinguished from *Fabacea* (*Leguminosæ*) by their regular petals and stamens, and especially by the odd segment of the calyx being posterior, and not anterior, and in that order. The genera of this order may be arranged under four groups or sub-orders, the principal distinctions of which will be seen in the following analysis:—

Carpels numerous.	
Ovaries superior.	*Rosaceæ* (proper).
Ovaries inferior.	*Pomeæ*.
Carpels solitary.	
Fruit a drupe.	*Amygdaleæ*.
Fruit a nut.	*Sanguisorbeæ*.

Rosaceæ proper, include the true Roses (*Roseæ*), the Cinquefoils (*Potentilleæ*), the Spiræas (*Spirææ*), and the Neuradas (*Neuradeæ*). They are herbaceous plants or shrubs. This family includes about 570 species and 20 genera, principally inhabitants of the temperate and cold zones of the northern hemisphere of the New and Old World; a very few are found on high land within the tropics, and a small number in the southern hemisphere. None of the plants of this section of the order are unwholesome; they are characterised by the presence of an astringent principle, which has led to the use of many of them in medicine, viz; ROSA; POTENTILLA; SPIRÆA; FRAGARIA; GEUM: DRYAS.—*Eng. Cyc.*

Pomeæ are known by the adhesion of their ovaries to the sides of the calyx, forming the fruit called a Pome. Their ovula are always in pairs. The tendency of the flowers of this family to revert to their normal state frequently affords instructive examples of morphological changes. The fruit of many of the species contains a considerable quantity of malic acid, which gives to the fruit its peculiar flavour. The Apple, Pear, Medlar, Quince, Service-Tree, and Mountain-Ash belong to this family. They are inhabitants of Europe, Northern Asia, the mountains of India, and North America. The genera are PYRUS; CYDONIA; AMELANCHIER; CRATÆGUS; COTONEASTER; MESPILUS.—*Eng. Cyc.*

Amygdaleæ have but a single carpel, which when ripe is a drupe, but they are also distinguished amongst *Rosaceæ* by their leaves containing hydrocyanic acid, and their bark yielding gum. They are natives exclusively of the northern hemisphere, where they are found in cold or temperate climates. Many of the species are poisonous, on account of the hydrocyanic acid they contain. They yield, however, some of our most valued fruits, as the Peach, Nectarine, Plum, Apricot, Cherry, and Almond, which last is the seed of the *Amygdalus communis*. The genera are AMYGDALEÆ; AMYGDALUS: PRUNUS.—*Eng. Cyc.*

Sanguisorbeæ are not only known by their solitary carpels but they are destitute of petals and have a hard thickened calyx. They are found wild in heaths, hedges, and exposed places in Europe, North and South America beyond the

tropics, and the Cape of Good Hope. Their principal property is astringency, and some of the species may be used as fodder. The genera are Sanguisorba; Poterium; Agrimonia.—*Eng. Cyc.*

(7200) ROSCOEA, a genus of Plants belonging to the natural order *Scitamineæ* or *Zingiberaceæ*, which was named by Sir J. E. Smith, in honour of the historian of the Medici, who elucidated the plants and remodelled the genera of the *Scitamineæ* in his beautiful work on that family. The species have been figured by Smith, Wallich, and Royle. The genus consists of only a few species, which are confined to the Himalaya Mountains, and is characterised by having spathaceous flowers, a single-leafed tubular calyx, corolla ringent, limb double, the outer tripartite, with the upper segment erect and arched. Inner limb two-lipped, ovary inferior, style inclosed in the furrow of the anther, which is two-lobed, incurved, surrounding the style with an appendage split at the base. The species of *Roscoea*, belonging to so tropical a family as the *Scitamineæ*, are generally accounted showy stove plants; but they are found only on the slopes of the Himalayas during the rainy seasons, when there is moisture with uniformity of temperature. *R. alpina* is found at as great an elevation as 9000 feet above the level of the sea, and on places whence the snow had just melted, like the snowdrop in early spring in European countries. —*Eng. Cyc.* Wight gives Roscoea alpina, 2013; lutea, 2013.2.

(7201) ROSELLE. Hibiscus Sabdariffa.

Yerra googoo. Tel.	Poolchay keeray, Tam.
Kaserica, Hind.	

The roselle plant, the red sorrel of the West Indies, is very widely diffused and its red sour calyx makes a fine flavored jelly, and preserve, which is a good substitute for cranberries.—*Faulkner.* This plant grows readily all over India, and is cultivated in most gardens, because its ripe, fleshy calyxes, have a pleasantly acid taste, and make excellent tarts and jelly: and in the West Indies, refreshing drinks. The stems cut when in flower, and the bark stripped off, and steeped immediately, a mass of fibres is displayed, the minute fibres of which are of a fine silky nature.

(7202) ROSE MALOES: Rosa Mallos: Liquid Storax. Liquidamber Altingaa? This is a thick scented gummous oil of the consistence of tar; it is brought from Persia via India to China; and when good has a pearly appearance. The price has declined much of late years; it used to sell for $ 30 per pecul.—*Morrison.* It is used for medicinal purposes.—*Williams' Middle Kingdom, Vol.* II. *page* 406.

(7203) ROSE WATER.

Gul-ab-ka-panee, Guz Hind,	Ab-i-gul. Pers.

The water distilled from roses, and put into carboys (large glass bottles of about three Imperial gallons capacity each) for sale. A large quantity is annually exported from the Persian Gulf to Bombay; that sold in Benares is obtained from Gazeepore, where it is largely distilled. Rose water is much esteemed on account of its great fragrance, and is chiefly used by the natives at the periods of their festivals and weddings.

(7204) ROSE WOOD.

Bois du rose, Fr.	Leno de rosa, Sp.
Rosen-holz, Ger.	Yerra goodda-chava curra, Tel.
Legno rodie, It.	
Pao de rosada, Por.	

Like to Iron-wood; Blackwood &c., this is a term given to the timber of several trees. One is a beautiful fancy wood, produced by a large tree found in Brazil, the Canary Islands; in Siam, whence it is largely exported by the Chinese; and other places. It is of a reddish colour, has an agreeable odour, and is esteemed according to the degree in which the darker parts are distinct from the purple red, which forms the ground. It is used for cabinet work, either whole or cut into veneer.—*Faulkner.*

Another Rose-wood is the *Lignum Rhodium*, or *Aspalathus*, (whence the Oleum Rhodii is obtained). It is heavy, oleaginous, somewhat sharp and bitter to the taste of a strong smell, and purple colour.

The *Chinese Rose-wood*, called by the natives Tze-tau, is odorous, of a reddish black colour, streaked, and full of fine veins, which appear to be painted. The manufactures of this wood are more valued in China than the varnished or japanned. There are baser kinds of Rose-wood of inferior value.—*Morrison.*

East Indian Blackwood or Rosewood, is an excellent heavy wood, suited for the best furniture. It can be procured in large quantities, and of considerable size; the wood contains much oil, which was exhibited in Cl. IV (by the Ganjam Local Committee). In large panels it is liable to split.—*M. E. J. R.*

Rosewood, used in Britain, is produced in the Brazils, the Canary Isles, the East Indies, and Africa. It is imported in very large slabs, or the halves of trees that average 18 inches wide. The best is from Rio de Janeiro, the second quality from Bahia, and the commonest from the East Indies: the latter is called East India Black-wood, although it happens to be the lightest and most red of the three; it is devoid of the powerful smell of the true rose-wood, which latter Dr. Lindley considers to be a species of Mimosa. The pores of the East India Rose-wood appear to contain less or none of the resinous matter, in which the odour like that of the flower Acacia armata, arises. Rose-wood contains so much gum and oil, that small splinters make excellent matches. The colours of rose-wood are from light hazel to deep purple, or nearly black: the tints are sometimes abruptly contrasted at other times striped or nearly uniform. The wood is very heavy; some specimens are close and fine

in the grain, whereas others are as open as coarse mahogany, or rather are more abundant in veins: the black streaks are sometimes particularly hard, and very destructive to the tools.

Next to mahogany, it is the most abundant of the furniture woods; a large quantity is cut into veneers for upholstery and cabinet work, and solid pieces are used for the same purposes, and for a great variety of turned articles of ordinary consumption.—*Tredgold.*

(7205) ROSES, OTTO OF.

Uttur, Guz. | Uttur-i-Gul, Pers.
Gulab-ka-Uttur. Hind.

This far-famed, highly valuable, and delightful perfume, is prepared in Persia, Upper Egypt, Tunis, Cashmere, and Ghazipore in Bengal. It is estimated that one hundred thousand roses, yield 180 grains or one tola of the Uttur. The otto of roses purchased in the bazars is generally adulterated with sandalwood and sweet oil; the genuine article being only procurable at a high price.—*Faulkner.* See Rose Attar.

(7206) ROSETTA-WOOD, is a good sized, East India wood, imported in logs 9 to 14 in diameter; it is handsomely veined; the general colour is a lively red-orange, (like the skin of the Malta orange,) with darker marks, which are sometimes nearly black; the wood is close, hard, and very beautiful when first cut, but soon gets darker.—*Holtz.*

(7207) ROSIN.

Rall, Guz. Hind.

A commercial name for the residium of the distillation of turpentine: it is light, hard, brittle, inflammable, transparent, dark, coloured substance. Several kinds are distinguished, as black or common, amber rosin, &c. It is used in the manufacture of soap, varnishes, and for other purposes.—*Faulkner.* See Resin and Dammer.

(7208) ROSMARINUS, a genus of Plants belonging to the natural order *Lamiaceæ*. The genera belonging to this order are perennial and possess the character of shrubs.—*Eng. Cyc.*

(7209) ROSMARINUS OFFICINALIS.

Rosemary, Europe, Asia Minor.
Ukleel ul jibbal, Hind. | Hasalban achsir, Arab.

Rosmarinus officinalis, the Common Rosemary, is an inhabitant of the southern parts of France, Spain, and Italy, the basin of the Mediterranean, and some parts of Asia Minor.—*Eng. Cyc.* The essential ingredient in the well known *Eau de la reine d' Hongrie* is the essential oil of this plant. It is a shrub three to four feet high, densely leafy. The oil is stated most positively to possess the power of encouraging the growth of hair and of curing baldness. It is the colouring ingredient of green pomatums.—*O'Shaughnessy, page* 488.

(7210) ROTHIA TRIFOLIATA.

Nurrey-pithen-keeray, Tam.

A small procumbent weed, with trifoliate leaves, used by the natives as greens, abundant every where.—*Jaffrey.*

(7211) ROTIFERA, Wheel-Animalcules, a class of animals placed by Ehrenberg among the *Infusoria*, under the name of *Rotatoria*. They have acquired these names on account of the apparent rotation of the disc-like organs which surround their mouths and which are covered by cilia. These creatures are very minute, and although some of the larger forms may be detected by the naked eye, their organisation can only be seen by the aid of the microscope. We are indebted to Leeuwenhoek for the discovery of their existence and the first account of their structure and habits. In the 'Philosophical Transactions' for 1702, he gave an account of the discovery of what is now called *Rotifer vulgaris*, one of the most common forms of these animals. He afterwards described another form, *Melicerta ringens*. The *Rotifera* are very widely diffused on the surface of the earth. They inhabit both fresh-waters and the ocean, and are found in the cold, temperate, and tropical parts of the earth. Although capable of swimming freely they are generally found near or attached to the leaves of plants. They are found constantly present in ponds and streams in which *Ceratophyllum*, *Callitriche*, *Valisneria*, and other fresh-water plants abound.

(7212) ROTTEN-STONE, a Mineral, occurring massive. Fracture uneven. Colour grayish, reddish, or blackish brown. Dull earthy and opaque. Soft, soils the fingers, and is fetid when rubbed or scraped. It is found near Bakewell, Derbyshire; and at Albany, in the state of New York. It is employed in polishing metals, &c. The analysis by R. Phillips gives—

Alumina	86
Silica	4
Carbonaceous matter . . .	10
Eng. Cyc.	—100

(7213) ROTTLERA, a genus of Plants named in honour of Dr. Rottler, belonging to the natural family *Euphorbiaceæ*. It is characterised by having male and female flowers upon different plants. Male: Calyx 3-5-partite; corolla none; stamens 30 to 40 [illegible] to the convex receptacle; fila[illegible] *rosaceæ* by their [illegible] at the base. Female: Ovary 2-[illegible]cid, and their [illegible]; style deeply 2-3-4-partite, [illegible]natives exclusively of the [illegible]cous, each 1-seeded. [illegible]where they are found [illegible] in the tropical parts [illegible]es. Many of the species [illegible] India, contains handsom[illegible] of the hydrocyanic [illegible] trees. *R. tetracocca* grows in Si[illegible]however, [illegible]s a hard and valuable timber. The [illegible] Pears of *R. tinctoria*, a native of the Coromandel coast, and extending to the forests of Northern India, are covered with short stiff hairs, which when rubbed off have the appearance of a powder of a fine red colour, which is employed in India in dyeing silk of a scarlet colour, and therefore forms an article of commerce in this country. Dr. Royle states that this strigose pubescence is also employed in India as an anthelmintic in the same

way that cowage is and, like it, probably acts mechanically in expelling intestinal worms.—*Eng. Cyc.* Dr. Wight in Icones, gives Rottlera dicocca, 1915; Indica, 1870-71; peltata, 1878-86; and tinctoria, 1915.

(7214) ROTTLERA TINCTORIA.

Cupela, also Poonag, also Tukla, HIND.	Shendree or Toong, DUK.
Sarnakassary mara, CAN.	Corunga Munje-mara, CAN.
Chendurapa chettoo, TEL.	
Capilapodie, TAM.	

Monkey faced tree, from these animals rubbing their faces with the fruit. A large tree with alternate, ovate oblong leaves, of a ferruginous colour beneath; flowers in the cold weather. Fruit size of a pea, covered with a red mealy powder, used as a dye.—*Riddell.* The tree is common in the Deccan and the Northern Circars,—*M. E. J. R.* also in the Kotah jungles and in Mewar.—*Gen. Med. Top. page* 211. It grows also in the Sikkim Himalaya, and yields a brown-dye.—*Hooker, Vol.* I. *page* 14. The red mealy powder which covers the capsules is used in Mysore to dye silk. Wood soft and inferior. Mysore. 16; 26.—*M. E. J. R.* These somewhat varied statements, are all, perhaps, reconciled in the following remarks, by Dr. Cleghorn, one of India's most accurate writers. He says "the stellate pubescence covering the 3-coccous capsule of this large tree, is collected for sale in Mysore, where it is used for dyeing silk an orange colour. In the Edinburgh Philosophical Journal, April 1855, Professor Anderson of Glasgow gives a very satisfactory report on the colouring matter of this dye, and the trials which he has made with it are sufficient "to show that it really merits the attention of silk dyers." The tree is widely spread over the Madras Presidency, and large supplies of the dye might be easily obtained. The colouring matter does not require a mordant, all that is necessary being to mix it, with water containing about half its weight of carbonate of soda. "On silk, the colour is a rich flame or orange tint of great beauty and extreme stability;" and "the fact that the material supplied by commerce, contains between 70 and 80 per cent. of real colouring matter, ought to induce the silk dyers of this country to turn their attention to it."—*M. E. J. R.* Ainslie describes it as a fine, reddish brown, light powder, which the Natives employ for dyeing a beautiful pale orange colour: he was for some time, a good deal at a loss to know from what exact plant it was obtained, till he discovered, in Dr. Buchanan's Journey through the countries of Mysore, Canara and Malabar, "that it is the red dust shaken from the dry fruit of the Rottlera tinctoria, and is an export from Malabar, where the tree is called Corunga Munje-marum. —*Ains. Mat. Med. p.* 146. Dr. Honigberger mentions that the *Kamila* or *Kamud* of the Lahore bazaars what Dr. Royle, in the Illustrated Catalogue of the Great Exhibition, nominates *Rerov.* It is taken to Lahore from the hills, in the form of coarse red powder; is reported to be the hairs of a pod from a tree, and is chiefly used as a purple dye. The Indian name of this article, *Kamila*, is probably a derivation from the Sanscrit "Kamila," signifying Jaundice, as the color of it is a yellowish-red.—*Thirty five years in the East by Dr. Honigberger, p.* 337. Dr. Irvine tells us that the kupila, the dust from the capsule of the fruit, is used to dye silk yellow, alum being used as the mordant: also that it is considered in medicine as of a warm nature, also anthelmintic; and given to children in "dai." Three or four massee are a dose: also used in ointments for herpetic eruptions, price two and a half seers for one rupee.—*Gen. Med. Top. p.* 142. Simmonds merely remarks that, a coloring matter is prepared from the dried fruit of the *Rottlera tinctoria*, by the natives of the East, to dye orange, which is a brilliant and tolerably permanent dye: and adds, it is apparently of a resinous nature.

(7215) ROUGE, a pigment of a beautiful rose colour, procured from the red colouring matter of safflower. It is brought from China spread on small papers, or in pots. See CARMINE.

(7216) ROUREA SOOKURTHOONTEE. CNESTIS MONADELPHA. The rourea abounds in the environs of Tavoy, where the air is often filled with fragrance from its thick snow-white flowers.—*Mason.*

(7217) ROXBURGHIACEÆ, *Roxburgh-Worts*, a natural order of Plants belonging to the class Dictyogens. The species are twining shrubs with tuberous roots; reticulated leaves, coriaceous, and with parallel secondary veins connecting several primary ribs; flowers large and showy, solitary, fœtid; perianth of four large petaloid divisions; stamens 4, hypogynous; anthers adnate, opening inwards, pointed, with connectives projecting far beyond the cells, which separate from the latter as far as their bases; pericarp 1-celled, 2-valved, with two clusters of seeds at the base. Seeds attached to long cords covered with loose hairs just below the seeds; embryo taper, in the axis of fleshy albumen, with the plumule lying within a slit. The plants of this small order are natives of the hot parts of India. There is but one genus—*Roxburghia*, the roots of a species of which are prepared with lime water, candied with sugar, and taken with tea. The flavour is insipid. (Lindley, *Vegetable Kingdom.*) *Eng Cyc.* Dr Wight gives Roxburghia gloriosoides, 2061.

(7218) ROYDSIA, an Indian genus of Plants allied to the natural order *Capparidaceæ*, named by Dr. Roxburgh in compliment to Sir. J. Royds. The genus consists of a single species indigenous in the forests of Silhet, where, with a stout stem and numerous branches, it climbs over the trees to a great extent, and flowers in the month of

March, diffusing a strong but pleasant odour from its numerous blossoms arranged in axillary racemes or terminal panicles. The leaves are alternate, oblong, coriaceous, smooth on both sides, and without stipules. The calyx is 6-partite and of a pale-yellow colour; corolla none; stamens numerous, with the filaments inserted on the apex of a short column; ovary pedicelled 3-celled, with two rows of ovules in each, attached to the axis; drupe berried, of the size of a large olive, orange-coloured; pulp abundant and yellow; nut oblong, single-celled and 3-valved; seed solitary, conformable to the nut. The plant is figured in Roxburgh's 'Coromandel Plants,' p. 289, and is well-suited to the hothouses of England.—*Eng. Cyc.*

(7219) ROYLEA, a Himalayan genus of Plants belonging to the natural order *Lamiaceæ* and tribe *Ballotæ*, named by Dr. Wallich in compliment to Dr. Royle, author of the 'Illustrations of the Botany of the Himalayan Mountains and of Cashmere,' who first found it on the Sirmore Mountains. The plant forms a handsome shrub, with many branches and an abundance of pale-green glaucous leaves. It is characterised by having the calyx ovate, tubular, 10 nerved, and semi-quinquefid; corolla shorter than the calyx, 2-lipped, lips unequal; stamens 4, didynamous, ascending under the upper lip; anthers biloculer; style bifid.—*Eng. Cyc.*

(7220) ROYLEA ELEGANS.
Patkuroo, Hind.

The only species known, is called Putkuroo by the natives of the mountains where it is indigenous. It is suited to the shrubberies of England.—*Eng. Cyc.* Is deemed a febrifuge, by the people at the Himalayas, like some species of Teucrium in Europe.—*O'Shaughnessy, p.* 492.

(7221) RUBIA, a genus of Plants belonging to the natural order *Galiaceæ*, containing about 40 species, found both in Europe and Asia. This genus is characterised by flowers monopetalous, superior; tube of the calyx ovate-globose limb scarcely any; corolla sub-campanulate, rotate, 5-partite; stamens 4-5, styles 2, short; berries 3, 1-seeded.—*Eng. Cyc.*

(7222) RUBIA CORDIFOLIA. DeCandolle. Manjith. Bengal Madder. Roxb. Rubia Manjista. Roxb. Indian Madder.

Manjista, Sans.	Manjistha; Munjeet
Manjtittie vayr, Tam.	Cho. munjeet, Hind.

The Munjeet of India, a native of Nepaul, &c., possesses very similar properties, to *R. Tinctorum* and is imported into England from Calcutta. The root is used as a substitute for that of *R. tinctorum*: it is known in commerce under the name of East Indian Madder, and is also employed in medicine. Like Madder, Munjeet was probably known from very early times, as Rodeen is given as the Greek name in Persian works on Materia Medica. R. *Chilensis* and *R. Relbun*, both natives of South America, are also esteemed there as dyes. Lindley, *Vegetable Kingdom*).—*Eng. Cyc.* Rubia cordifolia. Indian madder, though not seen in the Tenasserim Provinces, is found in Burmah.—*Mason.* It is much cultivated in Boondee, Kotah, and Mewar, in black loam, the root is largely exported. A beautiful crimson lake colour is dyed with it in Rajpootanah.—*Irvine.* The Hakeems are in the habit of prescribing an infusion of it, as a grateful and strengthening drink, to weakly women after lying in. Manjeittie is also called in Tamools Sawil codie.—*Ains. Mat. Med. p.* 82. *Rubia Munjista* is substituted in Lahore and Hindostan for the Rubia tinctorum used in Europe. I believe this article (important in a commercial view at Lahore) is now also cultivated in Europe. Camel loads of madder are brought from Banu and Tonk (on the west side of the Indus) to Lahore. On the Cashmerean mountains this plant is met with growing wild, but is not used.—*Thirty-five years in the East, by Dr. Honig. p.* 337. See Madder.

(7223) RUBIA TINCTORUM. Madder.
Menjithe. Hind.

R. tinctorum, Madder, has been long known, and was employed in medicine even in the time of Hippocrates, but is valued chiefly as a dye. It has a diffuse brittle-branched stem, angular, very rough, with sharp hooks; leaves 4 or 6 in a whorl, lanceolate or oblong-lanceolate, mucronate, somewhat membranous with pinnated veins; flowers small and white; lobes of the corolla ovate-lanceolate, apiculate; anthers ovate-oblong; stigmas conical. It is a native of Europe and Asia Minor, but is now extensively cultivated in Holland and France; the culture has likewise been attempted, and successfully, in Great Britain but the English madder could not be sold so cheap as the foreign; it is therefore still largely imported, chiefly from Holland, France, Italy, and Turkey, though since cochineal has become cheaper, it is much used for the same purposes. It is employed by dyers and calico-printers as a red and scarlet dye. It has also the singular property of turning red the bones and secretions of fowls and other animals fed on it. The two species, R. tinctorum and R. manjista, are natives of the south of Europe, the Levant, and Asia Minor, cultivated in India, and in many parts of Europe. The roots are creeping, the thickness of the little finger, very long and branching, provided with numerous articulations, and tough fibrils, epidermis thin, pale brown, bark and meditullium intensely red. The odour is weak and peculiar, taste bitter and styptic. According to Kuhlman's analysis the roots contain red colouring matter, (*Alizarin*, Robiquet,) yellow do, (*Xanthine*, Kuhl.) woody fibre, mucilage, gum, sugar, bitter matter, resin, salts albumen, &c; *Alizarin* occurs in orange red crystals, tasteless, inodorous, little soluble in cold, but soluble in boiling water also in alcohol, ether,

the fixed oils, and alkalies. The alcoholic solution is rose coloured, the etherial golden, the alkaline violet or blue. A solution of alum added to a solution of alizarin, and precipitated by potash, gives a rose lake of the most charming tint. *Xanthine* is yellow, very soluble in water and alcohol, slightly in ether; the solution passes to orange-red by contact with alkalies, to lemon-yellow by acids. It is devoid of odour, but has a sweetish bitter taste. The red colouring matter of madder tinges the bones, milk, and urine of animals if fed on the roots. The great consumption of madder is as a dye stuff for giving a red colour to wool, silk and cotton. In pharmacy the roots are sometimes used for colouring ointments.—*O'Shaughnessy, page* 378.

(7224) RUBUS (the Latin *Rubus*, a Bramble) a genus of Plants belonging to the natural order *Rosaceæ*, and to the section *Potentilleæ* of the sub order *Rosaceæ* proper. This genus, like that of *Rosa*, has proved a source of difficulty and difference amongst botanists. Some writers on the British Flora have described upwards of twenty-five species, whilst others have reduced them to four or five, or even two.—*Eng. Cyc.* Dr. Wight gives Rubus Gowreephul, 230; lasiocarpus, 232; rugosus, 225; Wallichianus, 231.

(7225) RUBUS CONCOLOR is found in the Himalayas, as also in Cashmere.—*Honig, p.* 337.

(7226) RUBUS FRUTICOSUS, Shrubby Bramble, or Common Blackberry, is one of the most common species of the genus. It has a 4-angled erect stem, rather tomentose, bearing recurved prickles, 3-5 leaflets, each on a secondary petiole; rose coloured or white flowers arranged on a panicle; reflexed sepals, almost without prickles; purplish black fruit. It is a native of almost all Europe, in hedges, thickets, and woods. There are no less than ten generally admitted varieties of this species and some botanists make many more. The fruit of this species and its varieties are well known as blackberries, or bumblekites, and also scald-berries, from their supposed power of giving scald-head to children.—*Eng. Cyc.*

(7227) RUBUS GOWREEPHUL, WILD RASPBERRY. Griffith says there is a species of rubus in the Tenasserim Provinces, and Wallich found one on the Irrawaddy; but whether either produces an edible fruit or not, I am unable to say. The existence of an indigenous species, though worthless itself, is however, interesting; as it indicates that the true raspberry might be propagated with success.—*Mason.*

(7228) RUBUS IDÆUS. Common Raspberry, or Mount Ida Bramble. The whole plant is villose, stem round, with slender recurved prickles; leaves pinnate, with 3 or 5 ovate serrated leaflets, tomentose beneath; flowers drooping; petals obovate, wedge-shaped, entire conniving, shorter than the calyx; carpels numerous, tomentose. It is a native of woods in Europe from Norway and Sweden to Spain and Greece. It is found also in Asia on the Himalayas, in the north Africa, and in America from Canada to Pennsylvania. It is found abundantly in almost every part of Great Britain and Ireland.—*Eng. Cyc. Rubus Idæus*, does not grow in Hindostan: a nearly allied species viz.

(7229) RUBUS INDICUS, ROTTL. BRAMBLE BERRY (Spec. of).

Gowry pull, HIND.

Gowry pull is the Hindoostanee name of a species of Bramble berry common amongst the woods betwixt Hurdwar and Sirinagar: it also grows plentifully in Mysore and Wynaad, but I know not the Canarese name of it.—*Ainslie, page* 225.

(7230) RUBUS LASIOCARPUS. ROSACEÆ. Blackberry.

Gowreephul. DUCK.

Now cultivated generally in the Deccan, and believed to have been first brought from the Mysore Hills. It grows easily from seed; a few of the ripe fruit rubbed on a sheet of paper, and dried in the sun, will enable you to forward the seed to friends at any distance. (The same with the strawberry.) The plants should never be nearer than four or five feet, and may be cut down at the commencement of the rains, when they will throw out fresh shoots, and bear fruit in abundance. As it requires little care, and only an occasional supply of water, this bramble forms a very perfect and secure hedge to a kitchen garden. The finest fruit is very inferior to a common raspberry.—*Riddell.*

(7231) RUBUS MICRANTHUS, Small-Flowered Bramble, has an upright, round, branched stem, pinnate leaves, with 5-7 oblong, ovate, doubly serrate, tomentose beneath, and green above leaflets, with small reddish-purple flowers arranged in corymbs, and black fruit. It is a native of Nepaul, and one of the most gigantic of the genus, attaining a height of 8 or 9 feet. It is easily distinguished by its nearly erect, smooth, dark mahogany-coloured shoots, and very long pinnate leaves. The shoots sometimes attain a length of 20 feet. There are two other species, *R. distans* and *R. asper*, found with this in Nepaul, which have been grown in England.—*Eng. Cyc.*

(7232) RUBUS RUGOSUS. The Raspberry. This plant never grows in the Deccan; a wild species is described by Graham as found in Mahabaleshwar.—*Riddell.*

(7233) RUBUS VULGARIS. RUBUS FRUTICOSUS like *R. Idæus*, grows at Cashmere.—*Thirty-five years in the East by Dr. Honig. p.* 337.

(7234) RUBY.

Kemboo also Segapoo kulloo, TAM.	Yacout, ARAB.
Lal, HIND.	Lankaratti, CYNG.
	Manekam, MALAY.

Colour blood-red or rose-red, sometimes a

tinge of violet; primary form as above, and generally occurs in 6-sided prisms. It is not so hard as the Sapphire, and is more readily cleaved. Like the Sapphire, it consists of pure alumina. "The largest oriental ruby known was brought from China to Prince Gargarin, vernor of Siberia; it afterwards came into the possession of Prince Menzikoff and now constitutes a jewel in the Imperial Crown of Russia." (Dana)—*Eng. Cyc. page* 151. This beautiful gem can be procured in Ceylon, but Rubies are still more abundant and of a much finer kind in the Dominions of Ava, whence they are brought to India.—*Ains. Mat. Med p.* 166.

(7235) *Spinelle Ruby.* Mr. Mason says, "By far the larger proportion of the rubies offered for sale, are, it is believed, spinelle rubies. I have a small a specimen which every native, who has seen it, regards as one of the best kind of rubies, or red sapphire, but its natural crystalline form is easily recognised, as a regular octahedron; while that of the oriental ruby is a six sided figure, or some of its modifications. They are seen of all shades. Blood red, the proper spinelle ruby; rose red, the balas ruby; orange red or rubicelle; and violet colored or almandine ruby. It is not an easy task to distinguish, accurately, the true character of the different stones offered for sale as rubies. Both Europeans and natives often make great mistakes. An English officer bought a "ruby" in Maulmain a few years ago for fifteen rupees, his friend bought one for five rupees: and the rubies were thought to be of nearly equal value; but on walking into a jeweler's shop in Calcutta, a year or two afterwards, the jeweler offered *four hundred* and *fifty* rupees for the one, but refused to give two rupees for the other, characterizing it as "a worthless garnet."—*Mason.*

(7236) *Rubies.* Captain Newbold mentions that fine rubies have from time to time been discovered in many of the corundum localities he enumerated, associated with this gem, particularly in the gneiss at Viralimodos and Sholasirasmany, and the natives informed him that it occurs in the Trichingode talook and at Mallapollaye, though comparatively speaking rare.—*M. J. L. & S.*

(7237) RUDBECKIA FULGIDA. This is a showy genus of plants, and will grow in any common soil, they attain a large size, and are therefore more adapted for a shrubbery; the colours chiefly yellow, and orange; propagated by seed or by dividing the roots.—*Riddell.* The name was given by Linnæus, to honor the memory of his predecessors the Rudbecks, father and son, in the botanical chair at Upsal. It belongs to the natural order *Compositæ*, and possesses many species. Some of these are well known in gardens. They are herbaceous, biennial and perennial.—*Eng. Cyc.*

(7238) RUDRA KUDAPA.

Rudra cuddapah, Tel. | Roodra kurpah, Hind.

(7239) RUE. In *India*, this name is given to the herb of *Ruta angustifolia*; of *R. Graveolens*; and of *R. Indica.*

Arooda, Tam. | Sadsah, Malay.
Suddap, Arab. & Duck. | Ruta Graveolens.
Saturee, Hinder.

Ruta graveolens. An evergreen shrub, grows freely in any good soil, used for fowls in the Roup, propagated by cuttings in damp weather.—*Jaffrey.* The leaves of Rue dried and burnt are much used in Southern India for the purpose of fumagating young children suffering from catarrh. They also used fresh bruised and mixed with Arrack as an external remedy in the first stages of paralytic affections. When dried in the shade and powdered the vytians prescribe this article in conjunction with certain aromatics in cases of Dyspepsia they likewise entertain the same notion regarding it that Dioscorides did of old, viz. that it is inimical to the fœtus in utero when given together with camphor and the sugar of the palmyra toddy.—*Ains. Materia Med: p.* 38. In making confection of Rue, the herb of dried rue the sudab of the bazars of N. W. India, may be substituted.—*Beng. Phar. p.* 273

(7240) RUELLIA, a genus of Plants belonging to the natural order *Acanthaceæ*, which was so named by Linnæus in compliment to J. Ruelle, physician of Francis I., who wrote commentaries on Dioscorides, as well as some other botanical works. The genus, as formerly constituted, embraced a great many Indian species, which are now distributed among some other genera. The species are distributed through the tropical and subtropical parts of Australia. It includes many highly ornamental plants, as are also those which have now been excluded from it: all are easily cultivated, and often to be seen in English hot-houses. Some of the species which have now been removed to other genera are found at considerable elevations on the sides of the Himalaya Mountains; of these the most remarkable is *Æchmanthera* formerly *Ruellia gossypina*, Which has its stems covered with a thick coating of white tomentum, which probably enables it to withstand a greater degree of cold than most others of the family. The leaves of *R. strepens* are subacid. A valuable dye, called Room, is obtained in Assam from a species of *Ruellia*. Wight gives Ruellia *litoralis*, 447; and punctata, 1563. Voigt and Roxburgh name and describe the following species viz.; balsamica; bracteata; cernua; comosa; dependens; fasciculata; flagelliformis; flava; hirsuta; hirta; imbricata; infundibuliformis; latebrosa; longifolia; maculata; obovata; patula; Pavala; racemosa; ringens; salicifolia; Sarmentosa; suffruticosa; triflora; uliginosa, and zeylanica.—*Voigt: Roxburgh.*

(7241) RUELLIA. *Species.* A species of Ruellia, under the name of "roum," is employed

in its raw state by the Khamptis and Lingphos to dye their clothes of a deep blue. It is described by the late Dr. Griffiths as "a valuable dye and highly worthy of attention." It might perhaps be usefully employed as the ground for black dye. —*Hooker.*

(7242) RUELLIA INDIGOFERA The Burmese cultivate a low Ruellia plant as a substitute for indigo which is the *room* of Assam, from which country it has probably been introduced. It forms a blue dye not inferior to that produced by the true indigo plant.—*Mason.*

(7243) RUELLIA INDIGOTICA. In China, says Fortune, in one part of the Chekiang province, and also amongst the Fung hwa mountains to the westward of Ningpo, there are large quantities of a blue dye produced, which is in fact the indigo of that part of the country. Those who have read my 'Wanderings in China,' published in 1846, may remember the account given there of a valuable kind of Indigo, made from a species of woad (Isatis indigotica) which is cultivated extensively in the level country a few miles to the westward of Shanghæ. The kind which attracted Mr. Fortune's attention in Chekiang is equally valuable, if not more so. It is made from a species of Ruellia, which until it gets a better name, may be called Ruellia indigotica. It is a curious circumstance that the same plant, apparently, has lately been discovered in the Assam country in India, where it is also cultivated for the blue dye it affords. I had an opportunity of examining it in the garden of the Agricultural and Horticultural Society at Calcutta, where it was standing alongside of the Chinese kind, to which it certainly bears a most striking resemblance: the point of identity will easily be determined when the plants come into flower. Strange it will be if it is ultimately found that this species, which produces a dye unknown to commerce, is in cultivation all the way across from the eastern shores of China to the borders of Bengal, and this is far from being improbable. This Ruellia seem to be easily cultivated, it grows most luxuriantly, and is no doubt very productive. Having evidently been found indigenous a little further to the south, in a warmer latitude, it is not hardy in the province of Chekiang any more than cotton is about Shanghae; but nevertheless it succeeds admirably as a summer crop. It is planted in the end of April or beginning of May, after the spring frosts are over, and is cleared from the ground in October before those of autumn make their appearance. During this period it attains a height of a foot or a foot and a half, becomes very bushy, and is densely covered with large green leaves. The Chinese method of preserving plants for next year's crop is most ingenious and well worth notice. Being somewhat tender, as I have already remarked, the roots which are left in the ground after the gathering season are all destroyed by the first frosts of winter. But the Chinese cultivator does not depend upon these for the crop of the following year, nor does he take them up or cover them in any way. They have done their duty for one year, and are now left to their fate. Cuttings are found to be much more vigorous and preductive than the old roots and to the formation and preservation of these cuttings the Chinese cultivator directs his attention. When the stems are cut down for the manufacture of indigo, a sufficient quantity have their leaves stripped off, and are afterwards taken into a house or shed to be properly prepared. The leaves thus stripped from the cuttings are thrown into the tanks with the other stems and leaves so that nothing is lost except what is actually required for the purposes of propagation. The stems are now tied up firmly in large bundles, each containing upwards of 100, and the ends of each bundle are cut across, so as to leave them perfectly neat and even both at top and bottom. These bundles are each about a foot long, and, of course, nearly round. Having been thus prepared they are carried to a dry shed or outhouse, where, in some snug corner, they are packed closely and firmly together, and banked round with very dry loam. A portion of the dry soil is also shaken in between the bundles, and this being done the operation is complete. Should the winter prove unusally severe, a little dry straw or litter is thrown over the surface of the cuttings, but nothing else is required. During the winter months the cuttings remain green and plump; and although no leaves are produced, a few roots are generally found formed, or in the act of forming, when the winter has passed and the season for planting has come round. In this state they are taken to the fields and planted The weather during the planting season is generally showery, as this happens about the change of the monsoon, when the air is charged with moisture. A few days of this warm showery weather is sufficient to establish the new crop, which now goes on growing with luxuriance, and requires little attention during the summer; indeed none, except keeping the land free from weeds. In the country where this dye is grown, there are numerous pits or tanks on the edges of the fields. These are usually circular in form; and one which I measured was eleven feet in diameter, and two feet in depth. About 400 catties of stems and leaves are thrown into a tank of this size, which is then filled to the brim with clear water. In five days the plants are partially decomposed, and the water has become lightish-green in colour. At this period the whole of the stems and leaves are removed from the tank with a flat-headed broom made of bamboo twigs, and an admirable instrument for the purpose. When every particle has been removed, the workmen employed give the water a circular and rapid motion with the brooms just noticed, which is continued for some time. Dur-

ing this part of the operation another man has employed himself in mixing about thirty catties of lime with water, which water has been taken out of the tank for the purpose. This is now thrown into the tank, and the rapid circular motion of the water is kept up for a few minutes longer. When the lime and water have been well mixed in this way the circular motion is allowed to cease. Four men now station themselves round the tank and commence beating the water with bamboo rakes made for this purpose. The beating process is a very gentle one; as it goes on the water gradually changes from a greenish hue to a dingy yellow, while the froth becomes of a beautiful bright blue. During the process the head workman takes a paleful of the liquid out of the tank and beats rapidly with his hand. Under this operation it changes colour at once, and its value is judged of by the hue it presents. The beating process generally lasts for about half an hour. At the end of this time the whole of the surface of the tank is covered with a thick coating of froth of the most brilliant colours, in which blue predominates, particularly near the edges. At this stage it being desirable to incorporate the froth with the liquid below it, I witnessed a most beautiful chemical operation which took me completely by surprise, and showed how universally must be the knowledge of the effect of throwing "oil upon the waters." A very small portion of cabbage oil—only a few drops—was thrown on the surface of the froth, the workmen then stirred and beat it gently with their flat brooms for a second or two, and the whole disappeared as if by some enchanter's wand. And so small a quantity of oil was necessary for this purpose that even when the cup had been emptied, and had only the oil that was necessarily adhering to its edges, it was thrown into another tank, and produced the desired effect. The liquid, which is now darker in colour is allowed to stand quiet for some hours, until the coloring matter has sunk to the lower stratum, when about two-thirds of the surface is drawn off and thrown away. The remaining third part is then drawn into a small square tank on a lower level, which is thatched over with straw and here it remains for three or four days. By this time the colouring matter has separated itself from the water, which is now entirely drained off—the dye occupying three or four inches of the bottom in the form of a thick paste, and of a beautiful blue colour. In this state it is packed in baskets, and exposed for sale in all the country towns in this part of China. What its intrinsic value may be when compared with the indigo of commerce, I have no means of ascertaining but it is largely used in this part of the world, where blue is the most fashionable colour, judging from the dresses of the people, and it is possible that with our knowledge of chemistry a colour of this kind might be greatly improved. After being grown and manufactured, as I have described, it is sold at rates varying from 50 to 100 cash a catty, say from 2*d* to 4*d* per lb. Some is sold as low as 30 cash, but this is very inferior, the greater part produced is sold at from 60 to 80 cash a catty, and it must be of a very superior quality if 100 cash is paid. Like the Shanghae indigo made from Isatis indigotica, it is called "Tien-ching" by the Chinese.—*Fortune.* Amongst other productions of the highland valleys, the ruellia, formerly noticed, is cultivated extensively for the blue dye which it affords. During the season of its preparation every mountain stream is colored and polluted with the refuse liquid drawn off from the tanks and the stench which fills the air is almost unendurable.—*A Res. among the Chi. page* 189.

(7244) RUELLIA RINGENS. Lin.

Upu-dala, Hort: Mal.

The juice of the leaves of this plant, boiled with a little salt, Rheede says, is supposed, on the Malabar coast, to correct a depraved state of the humours. See Hortus Malabaricus. Part 9th *p.* 125.

(7245) RUELLIA STREPENS. Whorl Flowered Ruellia.

Kirendinyagum, Tam. | Grendie Tagarum Sans.

The small purple coloured leaves and berries of this low growing plant are sub-acrid and bitterish to the taste. When bruised and mixed with castor oil they form a valuable application in cases of children's carpangs.—*Ains. Mat. Med. p.* 83.

(7246) RUFFICKEE, a plant from the fibres of the bark of which the Lepchas near Darjeling make remarkably light and strong fishing nets.

(7247) RUGS, Woollen. The principal site of the manufacture of these rugs was long the town of Ellore, in the Northern Circars of the Madras Presidency, but they are now made in Mysore and although of any size, to order, they are usually three feet broad and six feet long, and are much employed as sleeping rugs, and rugs for the drawing room. They have latterly been exported largely to England where they are employed as hearth rugs: they are of various colours, prettily arranged, sell for four Rupees there, to rupees fourteen, according to size.

(7248) RUM.

Rum, Guz. Hind.

A spirit procured by distilling a fermented fluid prepared from the refuse in the operation for making sugar the peculiar flavour being derived from an essential oil existing in the juice of the cane. The best is made from molasses, and it is preferred when well kept, of good age, considerable body, smooth oily taste, and a brownish transparent colour. Bengal, the West India Islands, and Guiana, are the countries chiefly distinguished for the produce of rum.—*Faulkner.*

(7249) RUMEX ACETOSA. SORREL.

Chuka ke Bing. Hind.

The seed is considered cooling and astringent: It is cultivated in Ajmeer.—*Gen. Med. Top. p.* 130.

(7250) RUMEX ALPINUS, or Monk's rhubarb, is found on the European Alps, the Crimea, and Mount Caucasus. The roots are large and purgative like rhubarb, and the whole plant so resembles the Rheum that Linnæus himself mistook one for the other.—*O'Shaughnessy, p.* 522.

(7251) RUMEX OBTUSIFOLIUS vegetates in Cashmere, and is eaten by the natives. Its root, under the name of Radix Spathiacuti, was formerly used as a purifier of the blood in chronic cutaneous diseases, but is now obsolete, both in India and in Europe, its active principle, Lapatin, must, however, have peculiar properties. From the decoctions of the dried roots of various sorts of sorrel, by the addition of alum, can be obtained a fine red color, at a low price and valuable to painters. Rumex undulatus (Royle) is *Hímaz* or *Pulkee.—Thirty five years in the East, by Dr. Honig. p.* 338.

(7252) RUMEX VESICARIUS. Lin. Country Sorrel.

Sookan keeray, Tam. | Chuckka ke baujee, Duk.

Cultivated for greens, &c., grows plentifully about Madras in the field during the rains. This plant has obtained the name of Sorrel from the English in India, owing to its great resemblance to the Rumex acetosa in taste and other natural qualities. It is an article of diet and is considered by the Natives as cooling and aperient.—*Ains. Mat. Med. p.* 257. This is of common native growth, and where water is abundant may be had for eight months in the year; it is sown in drills or on the edges around other beds; the leaves are sold in bundles from one to two pice a seer. There is also another species called the Indian Red Sorrel. —*Riddell.*

(7253) RUMINANTIA, Cuvier's name for his eighth order of Mammiferes. They constitute the *pecora* of Linnæus. Cuvier remarks that this is perhaps the most natural and the best defined of the class; for these animals have the air of being nearly all constructed on the same model; and the camels alone present some small exceptions to the common character. Cuvier makes the Ruminants consist of two divisions;—first, those without horns; secondly, those with horns. The first division embraces the Camels (*Camelus* Linn.), or the Camels properly so called, and the Llamas; and the Chevrotains (*Moschus*, Linn.). Secondly, all the rest of the Ruminants, of the male sex at least, have two horns or prominences, more or less long, projecting from the frontal bones, which is not found in any other family of mammals. In some, these prominences are covered with a case of elastic substance composed, as it were, of agglutinated hairs, which grows in layers, and during the whole life of the animal. The name horn (corne) is particularly applied. The bony prominence or core which this case envelops, grows, like it, during the whole life of the animal, and is never shed. Such are the horns of oxen, sheep, goats, and antelopes. In others the prominences are invested only with a hairy skin, which is continued from that of the head, and is never destroyed during life. These prominences are never shed. Finally, in the great genus *Cervus*, Linn., the prominences covered during a certain period with a hairy or velvety skin resembling that of the rest of the head, have at their base a ring of bony tubercles, which, as it increases, compresses and obliterates the nutrient vessels of that skin, which, when the horn is complete, dries and is removed. The naked bony prominence separates in due time from the skull, to which it grew, falls, and the animal becomes defenceless. But new horns soon begin to bud, ordinarily, and while the animal is in the vigour of life, larger than the preceding ones, and destined to fall in their turn. These horns, purely osseous and subjected to periodical changes, are termed by the French Bois, and are known in England by the name of Antlers. Mr. Swainson divides the *Ungulata* into the following five tribes—*Ruminantes*, *Pachydermes*, *Anoplotheres*, *Edentates*, and *Solipedes*. The *Ruminantes*, are thus arranged:—

1. Sub-typical group.—Horns sheathing; form gracile, slender.

Family *Antilopidæ*. ANTILOPEÆ. (Sw.——*Capridæ*, Smith).

Genera.- *Dicranocerus*, Sm.; *Aigocerus*, Sm.; *Oryx*, Sm.; *Gazella* Sm.; *Antilope*, Sm.; *Redunca*, Sm.; *Tragulus*, Sm.; *Raphicerus*, Sm.; *Tetraceros*, Leach; *Cephalophus*, Sm.; *Neotragus*, Sm.; *Tragelaphus*, Sm.; *Nemorhædus*, Sm., *Rupicapra*, *Ant*, Sm.; *Aplocerus*, Sm.; *Capra*, Auct. *Ovis*, Auct; *Damalis*, Sm.; *Aeronotus*, Sm.; *Boselaphus*, Sm.; *Strepsiceros*, Sm.; *Portax*, Sm.

2. Typical.—Horns sheathing; form heavy, robust. Family *Bovidæ*, Sm. [BOVIDÆ.]

		Genera and Subgenera
		1. *Alce*, Sm (Subgenera *Rangifer* Sm., *Dama*, Sm.)
		2. *Cervus*, Linn., Sw. (Subgenera *Rusa*, Sm; *Axis*, Sm.)
		3. *Capreolus*, Sm (Subgenus, *Mazama*, Sm.)
		4. *Subulo*, Sm.
		5. *Stylocerus*, Sm.
3. Aberrant. Horns solid, deciduous. (*Cervida*, Sm; *Cervus*, Linn.) [CERVIDÆ]	Horns wanting, fore legs shorter than the hinder. (*Moschidæ*, Sw.) [MOSCHIDÆ]	1. *Moschus*, Linn
	Horns very short, covered with a skin. (*Camelopardæ* Sw.) [GIRAFFA]	1. *Camelopardalis*, Antiq.

The tribe *Solipedes*, which immediately follows

the Camelopards, consists of the genera *Camelus*, *Auchenia*, and *Equus*. Thus the Camels and Llamas, with which Colonel Smith, following Cuvier, commences the Ruminants, are placed by Mr. Swainson at the conclusion. With the exception of this and a few other modifications, the two arrangements are similar.—*Eng. Cyc.*

(7254) RUMPHIA, a genus of Plants named by Linnæus in honour of George Eberhard Rumph, is only known from a figure of Rheede published in his 'Hortus Malabaricus,' vol., iv., t. 11. who describes it as being found in Parabaroo and other provinces of Malabar. It has not been seen by any modern botanist. It is usually referred to the natural family of *Terebinthaceæ*, and to the sub-order *Burseræe*. It has a tubular trifid calyx, 3 oblong petals of the corolla ; stamens 3, equal to the petals, and exserted. The ovary is single, 3-cornered ; style one ; drupe coriaceous, turbinate, 3-furrowed, with the nut 3-celled, 3-seeded. But Messrs. Wight and Arnott remark, that as each apparent stamen may be composed of several filaments, this doubtful genus would be brought near *Byttneriaceæ*.

(7255) RUNGPORE, produces silk corahs. Megilli cloths made of pat (Corchorus olitorius), ginger (the best in Bengal), and tobacco of an excellent quality : and from the neighbouring country of Bhotan, specimens of the beautful long glossy hair of the tail of the Yak of which chowrees are made.—*M. C. C.*

(7256) RUPICOLINÆ, a sub-family of Insessorial Birds allied to the Manakins and generally arranged under the family *Pipridæ*.

(7257) *Calyptomena* (Raffles ; *Rupicola* (Temminck).—This very singular and beautiful bird is about 6½ inches in length. Its colour is a brilliant green, like that of the parrots, It is the Tampo Pinang of the Malays. It is a native of Singapore and the interior of Sumatra. Sir Stamford Raffles states that this species is found in the retired parts of forests, and as it is of the colour of the leaves, and perches high, it is not easily procured. He further tells us that the stomach contained nothing but vegetable substances, chiefly wild grains. Dr. Horsfield observes that the bill greatly resembles that of the genera *Rupicola*, *Pipra*, *Phibalura*, *Pardalotus*, *Platyrhynchus*, and *Procnias*.—*Eng. Cyc.*

(7258) RUPPELLIA (Milns-Edward), a genus of *Crustacea* belonging to the family *Cancerida* (Canceriens Arques), established on the *Cancer tenax* of the German zoologist and traveller Ruppell, and considered by M. Milne-Edwards as the type of the small group which leads to the genera *Ozius* and *Eriphia*. The form of the carapace approximates closely to that of *Xantho* and *Ozius* ; dorsal buckler slightly curved, and about one and a half as wide as it is long : the orbits are nearly circular, and are directed upwards and forwards. The interal antennæ bend back directly outwards, as in *Xantho*, &c.

(7259) RUPPELLIA TENAX, Cancer Tenax, Ruppell, has the upper border of the orbit marked by two fissures separated by a smal tooth ; there is a fissure at its external angle and two teeth at its lower borders. Lengtl about two inches. It is a native of the Red Sea.

(7260) RUSHES, GRASSES AND SEDGES. Although these substances are extensively used in India for the manufacture of mats ropes, baskets, and thatching, there was but a poo display of them in the Exhibition. The Travancore Local Committee and the Canara Local Committee exhibit the *Cyperus textilis*, and a finer kind of grass called kooray or koaray both used for making mats. The celebrated mats o Paulghaut and Cochin are noticed in anothe class. Several species of Typha, Juncus, and Saccharum are known to abound in this Presidency, and to be applied to useful purposes. The *Phrynium dichotomum* of Bengal is used fo making the sital patee mat.—*M. E. J. R.*

(7261) RUSOT. Extract of Barberry.—Berberidis Extractum.—Extract of bark and wood of the Barberry, (Berberis) several species ; deep yellow colour, totally soluble in water —*Beng. Phar.*

(7262) RUSSELIA. *Scrophulariaceæ*. This plant with rush like branches bears a deep scarlet trumpet-shaped flower, hanging in long axillary peduncles down the stalk : it blossoms during the greater part of the year, and is highly ornamental, growing luxuriantly in a rich soil It is propagated by layers or cuttings.

(7263) RUSSIA LEATHER.

Cuir de Russie, Fr.	Jachta, Por.
Juften, Ger.	Juft, Rus.
Cuojo di Russia, It.	Moscovia, Sp.

The tanned hides of oxen, manufactured in manner peculiar to that country. The leather i soft, has a strongly prominent grain, a grea deal of lustre, and a powerful and peculiar odour The colours are principally red or black ; th former is much esteemed for binding books, an making articles where a fine durable leather i required the latter is chiefly in demand in Rus sia for shoe and boot making.—*Faulkner.*

(7264) RUST, RED RAG, Red Robin, Red Gum. Uredo rubigo and U. linearis are fung which attack wheat in England.—*Hassell.*

(7265) RUTA, a genus of plants belongin to the natural order *Rutaceæ*. The following is description of this genus :—Calyx 4-partite, deciduous, shorter than the petals, which are fou and unguiculate, with the limb vaulted. Stamens eight, longer than the petals, filament subulate, glabrous ; anthers ovate, obtuse. Receptacle broader than the ovary, marked roun with eight nectariferous pores, bearing the peta and stamens at the base. Carpels 4, partly con bined by means of the central axis (gynobas

into one 4-lobed ovary, ovules 6-12 in each cell. Styles 4, distinct at the base, united upwards into a single pistil which is attenuated towards the apex. Stigmas 4. Capsules 4, partly united dehiscing internally at the apex. Seeds dotted. The species of this genus are suffrutescent, herbaceous, or perennial plants, with alternate exstipulate pinnated or decompound leaves covered with pellucid dots. The flowers are yellow rarely white, and disposed in terminal corymbs or racemes. De Candolle enumerates 24 species of *Ruta*, of which comparatively few are generally known or cultivated.—*Eng. Cyc.*

(7266) RUTA ALBIFLORA, (white-flowered rue) is common on the Himalayas, at an elevation of 5000 to 8000 feet.

(7267) RUTA ANGUSTIFOLIA, (narrow-leaved rue.) (Sudab) is met with in gardens in India, and used medicinally,—*O'Sh. page* 260.

(7268) RUTA GRAVEOLENS. RUE

The herb.

Ruta graveolens, Common Rue, is a glaucous hairless erect herb or half-shrubby plant, with a strong heavy unpleasant smell, growing to the height of about two feet. The leaves are supradecompound, alternate, their lateral lobes linear or nearly so; the terminal ones obovate; they and all other parts of the plant are covered with transparent dots. Carpels terminal, leafless, trichotomous cymose; petals four, wavy concave, a little irregularly toothed. Fruit roundish, warted, four-lobed, each lobe opening into two valves. Rue is sometimes called Herb-Grace, or the Herb of Grace and in some parts of England Ave-Grace. This name is said to have been given to it on account of its use in exorcisms. In company with rosemary it has been used from time immemorial as an emblem of remembrance and grace on account of its evergreen foliage. The stamens are remarkable for their presenting an instance of vegetable irritability. When the time is come for the pollen to be introduced into the stigma, and thus presented to the ovules, the stamens, which are hard and rigid, and almost at right angles with the style, approach the stigma one by one, and after remaining in contact with it long enough to discharge their pollen, they return back to their original position parallel with the petals.—*Eng. Cyc.*

(7269) RUTACEÆ, a natural order of Polypetalous Exogenous Plants, characterised by the possession of hypogynous stamens, two or three times as many as the petals cohering carpels with from 3 to 5 valves, an entire ovarium with several cells, imbricate calyx with four or five divisions, symmetrical hermaphrodite flowers with petals either wanting or as many as the lobes of the calyx, mostly twisted in æstivation. Fruit capsular, the sarcocarp mostly separating from the endocarp. Leaves without stipules, opposite or alternate, simple, deeply lobed or pinnate, and covered commonly with pellucid resinous dots. They are trees, small shrubs, or herbaceous plants.—*Eng. Cyc.*

This order embraces the *Rutæ* and *Diosmeæ* of A. de Jussieu, which are now made the principal sections of *Rutaceæ*. *Rutæ* are known by their seeds containing albumen, and by the sarcocarp of the fruit not being separable from the endocarp. In *Diosmeæ* the seeds have no albumen, and the sarcocarp and endocarp are separable into distinct bodies when the fruit is ripe. A. St. Hilare says that the observation of the adhesion of the sarcocarp and endocarp in *Rutæ* has been made on unripe specimens of the plants, and that when ripe they are as separable as in *Diosmeæ*. Whatever may be the real state of the case, the two sections are too obviously related in structure and general properties to permit of so slight differences elevating them into the importance of distinct natural orders. *Rutaceæ* agree with *Aurantiaceæ* in their dotted leaves, definite stamens, and fleshy disc. With *Xanthoxylaceæ*, *Simarubaceæ*, and *Humiriaceæ* they have also many points of analogy. They are closely allied to *Zygophyllaceæ* through *Peganum*, which Jussieu and other writers place amongst *Rutaceæ*. They are found in the south of Europe, and in our hemisphere extend as far as the limits of the Old World. *Diosma* and allied genera are found at the Cape of Good Hope. Australia possesses Boronias, Phebaliums, Correas, &c.; and great numbers are found in the equinoctial regions of America. Many of the plants of this order emit a powerful and usually offensive odour from the glands that cover their whole surface. These glands are sometimes so full of a volatile oil, that in hot weather the atmosphere surrounding the plant becomes charged with it, so that a lighted taper brought near the plant will cause the air to inflame. This is especially the case with *Dictamnus*. The Diosmas, or Bucku Plants, are used in medicine as antispasmodics. The celebrated Angostura Bark is produced by a plant (*Galipea officinalis*) belonging to this order.—*Royle.*

(7270) RYE.

Rug, Dan.	Secale Lat.
Rog, Dut.	Rosch, Sd, Jar, Rus.
Seigle, Fr.	Centeno, Sp.
Roken; Ger.	

A species of grain (*Secale Cereale*), coming nearer in its properties to wheat, than any other grain. It is the bread corn of Germany and Russia; and being of less value to the English farmer than barley, oats, or pease, is, in consequence, very little cultivated in Great Britain.—*Faulkner.*

(7271) RYE FLOUR, is obtained from the Secale cereale, and the seeds are met with in the market, derived of husk. Rye flower is said to be somewhat laxative. The roasted grains are not unfrequently employed in the adulteration of coffee.—*Hassell. Rye Flour*, or meal does not form a paste like wheat flower.—*Hassell.*

S.

(7272) SABADILLA. Fruit of Veratrum Sabadilla, and several other Melanthaceæ.—*Ben. Phar.*

(7273) SABLE.

Zibelline, Fr.	Zibellino, It.
Zobel, Ger.	Sohol, Rus.

A species of weasel (*Mustela Zibellina*), celebrated for the fine quality of its fur, the hairs of which turn with equal ease in very direction. Its colour is generally of a deep glossy brown or black, and sometimes, though very rarely, yellow and white. This animal is a native of Northern Europe and Siberia.—*Faulkner.*

(7274) SABLE FISH : Clupea, Spec.

Willum, Meen, Tam. | Willum mutchie, Duk.

(7275) SACCHARUM, a genus of Indian grasses, and species of which in addition to the *Moonja* and *Shur*, q : v. are used for thatching and for screens, and some for making writing pens and for arrows.— *Royle.* This genus of Plants belongs to the natural order *Graminaceæ.* One of the species yields the well-known product sugar, and is called the Sugar-Cane. The Sugar-Cane was introduced by the Saracens into the south of Europe, but the period is not well ascertained. Gibbon says they introduced it into Sicily soon after they got possession of the island. About the year 1420 sugar was much cultivated by the Portugese in Madeira. In 1503 we read of sugar being imported from the Canaries, and in 1506 sugar-canes were carried thence to Hispaniola in the West Indies. But, besides the Indian cane, another, and a much more prolific kind, that of Otaheite, was introduced into the West Indies about 1794, and about the same time, or in 1796, the China sugar-cane was introduced into India. The Chinese and Indian seem both therefore to have had independent means, that is, distinct plants from which they could extract sugar ; and, as history shews, they did so at very early periods. The genus *Saccharum* contains numerous species, which are usually easily distinguished by their highly ornamental nature,by the light or feathery or rather silk like inflorescence. The species are widely distributed through the tropical parts of the world. The genus is distinguished by the spikelets being all fertile and in pairs, one sessile, the other stalked, articulated at the base, 2-flowered, the lower floret neuter with one palea, the upper hermaphrodite with two paleæ. Glumes 2, membranous. Paleæ transparent, awnless ; those of the hermaphrodite flowers minute, unequal. Stamens 3. Ovary smooth ; styles 2, long; stigmas feathered with simple hairs. Scales 2, distinct, obscurely 2 or 3-lobed at the point. Caryopsis smooth. Some of the species of *Saccharum*, owing to the silex in their cuticle, are so durable that they are employed in India for thatching. such as *S. canaliculatum* and *S. cylindricum.* This is the case with *S. spontaneum*, which also makes good mats. The natives of Bengal make their pens of the narrow stems of *S. semidecumbens* and of *S. fuscum.* The latter, as well as the culms of *S. procerum*, are also used for screens and other economical purposes.—*Eng. Cyc.*

(7276) SACCHARUM CYLINDRICUM. *Syn.* Saguerus Cylindrica. Horses tail grass. Oola, Hind.

Grows on the Ajmere plains and flowers early in the rains.—*Genl. Med. Top. p.* 174.

(7277) SACCHARUM MOONJA. Surpar. Surpata, Hind.—*Gen. Med. Top. page* 174.

The Moonja is indigenous to India, it is collected after the rainy season. It is possessed of great tenacity it is used as rigging in all the vessels above Sukkur. It would form an ample supply of half-stuff for paper makers.—*Royle.* It is common at Ajmeer, in the valleys, and very abundant, along with the saccharum procerum, near Jaepoor. The best moonj is made from the floral leaves of this plant, and the best sirkee from the culms. The plant is distinguished from saccharum procerum by the height, which is inferior, the fineness of the culm and narrowness of the leaves.—*Irvine, p.* 175. The Saccharum Munja is used in Bengal for making strong ropes for tying up cattle and drawing water.—*M. E. J. R.* This, the *Moonja* of the natives (*Saccharum Munja*), is collected after the rainy season and kept for use, as it is employed in tying up their cattle at night and for ropes for their Persian wheels. It is said also to be one of the grasses employed for making tow ropes by the boatmen about Benares.—*Royle.* Mr. Burns, of the Indus Flotilla, has mentioned that the boatmen of the Indus universally employed the Moonj (probably the above *Saccharum Munja*) as a towing rope and for the rigging of their vessels, in all places above Sukkur. But below that place coir rope is very generally employed, being better able, it is believed, to stand the action of salt water. The Moonja, however, is possessed of great tenacity, as is evident from two-inch ropes, often fifty fathoms in length, made of its fibres, being sufficient for dragging their largest or 1200-maund boats up the Indus, and consequently against the full force of the

stream, even round projecting points. The rope is also possessed of lightness, so advantageous for rigging, and is capable, also, of bearing, without injury, alternate exposure to wet and to subsequent drying. Both qualities being essential for a tow-rope. Mr. Burns has also informed him that plants growing beyond the range of the overflowings of the river, or of the influence of the tides -that is, in the interior of the country, where, indeed, it grows in vast abundance -are possessed of the greatest strength. The upper leaves, about a foot or so in length, are preferred and collected. Having been made up into bundles, they are kept for use. When required for twisting into rope, they are first moistened in water, two men then, sitting opposite on each other, take one of these moist bundles and beat it alternately with mallets, until the loose cellular are separated from the fibrous parts. These are then ready for twisting into the ropes which are so extensively employed on the Indus. It is evident that a continuation of the same process, or the employment of the *Dhenkee* of India, would afford a very ample supply of half-stuff for paper makers, and at a cheap rate. -*Royle, Ind. Fibres, page* 30. Griffith collected nearly one hundred different grasses in the Tenasserim provinces,but Mr Mason was not aware that the description of a single species has ever been published. —*Mason.*

(7278) SACCHARUM OFFICINARUM. SUGAR CANE. Lin.

Karumboo, TAM.	Tebu, MALAY.
Gunna, DUCK.	Itchootunda, SANS
Cherooka, TEL.	*Ains. Mat. Med. p.* 264.

Saccharum officinarum, the best known species, or that yielding sugar in India, is cultivated in all parts of that country, and several varieties are known. It was introduced into the south of Europe and the Canaries, and thence into the West Indies. Another species introduced from China, was named *S. Sinense* by Dr. Roxburgh. It was extensively distributed throughout India, and still is so to some extent, as the canes are large, rich in juice, and hard enough to resist the attacks of the white ants. Within the last few years, the Otaheite sugar-cane has been introduced from the Mauritius into India, and rapidly spread through the country. It is no doubt the same species that was many years since introduced into the West Indies. It is probably the Canne de Haite of Tussac, or *S. violaceum.—Eng. Cyc.* See SUGAR.

(7279) SACCHARUM PROCERUM. Lofty Saccharum, Sirkunda; Sarkara. HIND, Very abundant every where on the sandy ridges and plains,of Ajmere where water is not very far from the surface. The lower parts of the culms, called "*sirkunda,*" are made into outside checks for door ways, &c.; the upper parts of the culms, called "*sirkee,*" are made into excellent neat and cheap mats, much used in thatching, &c. the floral leaves are made into "*moonj,*" by separating the fibres, by beating the leaves; this is very much used to make string and rope. -*Gen. Med. Top. p.* 175.

(7280) SACCHARUM SARA.

Shura Goondra, SUR. HIND.

Common in the plains of India. The culms are finer and stronger than surkunda, and are used to make arrows of, in preference to the other species when obtainable. The species of saccharum are often confounded by the natives — *Gen. Med. Top. page* 175. Saccharum Sara, yields the common "kulm" or *Reed Pen* with which in India, the Arabic and Persian characters are written. The *Shar* or *Sara* of Bengal (*Saccharum Sara*), or the Pen reed grass, Mr. Henly informs Dr. Royle is employed by the boatmen about Allahabad and Mirzapore, and esteemed as a tow-line for its strength and durability even when exposed to the action of water. It is said to be beaten into a rude fibre and then twisted into a rope. -*Royle.*

(7281) SACCHARUM SPONTANEUM: THATCHING GRASS.

Kus; Kush; Kagara, HIND.

Very abundant in the plains, of Ajmere where the blossom in the rains has a beautiful silvery appearance. Brooms are made of the culms,string of the leaves, and the whole is used to thatch with.—*Genl. Med. Top. page* 175. The Karens in Amherst Province cover their houses with the tall grasses which are so abundant on the Coast, and a few Europeans prefer this thatch to that made from the nipa. Two different species of grass Imperata cylindrica, SYN. Saccharum cylindricum, and Saccharum spontaneum,are used for this purpose,both of which were formerly referred to the genus which produces sugar cane. But the sugar grass seen in Maulmain, which flowers two or three feet high, has been removed since Roxburgh wrote, into the genus Imperata. This is one of the grasses used for thatch, and is often mistaken for *Saccharum spontaneum*, which is the other.—*Mason.*

(7282) SACCOLABIUM, a genus of Plants belonging to the tribe *Vandeæ* and the natural order *Orchidaceæ*, now extensively cultivated in hot-houses especially dedicated to their cultivation. This Asiatic genus, is found in the Indian Archipelago, the Malay Peninsula, and thence extending north along the Himalayan Mountains to 30° 4 N. lat., where *S. guttatum* is found on trees, as well as in more southern latitudes. The genus consists of caulescent epiphytes, with 2-rowed coriaceous leaves, which are often oblique at the apex. The flowers are axillary, and either racemose or solitary.—*Eng. Cyc.* Dr. Wight gives Saccolabium guttatum, 1745-6; niveum, 1676; paniculatum, 1676; papillosum, 1672; Rheedii, 1745-6; rubrum,1673; speciosum,1674-75; and Wightianum, 917.

(7283) SACCOLABIUM RETUSUM AND S. GUTTATUM: SPOTTED SACCOLABIUM.

Syn. Acrides guttatum.

One of the noblest orchids in the Tenasserim Provinces belongs to the saccolabium, or bag-lip-genus; the lip forming a bag or spur. The flowers are numerous, white, spotted with rose-violet, and stand on little pedicels all around the stalk so as to form an elegant plume sometimes a foot long, which give the trees on which they grow a most princely appearance. They are profusely multiplied in the neighborhood of Maulmain, and are highly valued in England.—*Mason.*

(7284) SADACHOO OR MADASOO WOOD.

Sadaichee marum, Tam.

(7285) SADDLES.

Selles. Fr.	Selle, It.
Sattel. Ger.	Sadla, Rus.
Zeen, Guz. Hind.	Selles, Sp.

Are seats adapted to the horse's back, formed of wooden frames, covered with leather, cloth, &c. English saddles are reckoned the best. Sherborne and Lynn, are particularly remarkable for this manufacture.—*Faulkner.* Though not coming exactly under the head of embroidery we may yet mention here from the articles at the Exhibition of 1851, the saddle-cloths and matchlock accoutrements from the Rajah of Kotah, a pattern was produced with gold headed nails, fixed into green velvet. The effect of this was so good as to be greatly admired by some of the best judges.—*Royle Arts &c. of India, p.* 508.

(7286) SAFFLOWER, Bastard Saffron. Carthamus tinctorius.

Usfar, Arab.	Kussumba, Guz. Hind.
Koosum, Kajeerah, Beng.	Zaffrone, It.
Cossumba, Can.	Kussumba, Mal.
Safflocr Bastered Saffran. Dut.	Polerroi, Prostoi schafran, Rus.
Kurtin, Egypt.	Kussumba Kum, lottora Sans.
Cartame Saffran batard, Fr.	Azafron bastardo, Sp.
Safflor, Ger.	Sendorkum, Tam.
	Kussumba chetto, Tel.

This annual plant grows in India Egypt, America, and some of the warmer parts of Europe. It is chiefly used for dyeing, producing different tints of red and orange, according to the alterative employed in combination. It also forms the basis of rouge. Safflower is produced in some parts of the Concans, and is extensively cultivated in Guzerat; that obtained from Bengal is considered superior to all the other Indian varieties.—*Faulkner.* Safflower was shown in the Great Exhibition from Celebes, Assam, the vicinity of Calcutta, Dacca, the states of Rajpootana and other places. There are two species: *Carthamus tinctorius*, which has small leaves and an orange flower; and *C. oxyacantha*, with larger leaves and a yellow flower, a native of Caucasus. The former is cultivated in Egypt, the Levant, &c., where it forms a considerable article of commerce. 6,633 cwts. of safflower were imported into the United Kingdom in 1835, of which about one-half was retained for home consumption. Of 5,352 cwts. imported in 1840, nearly the whole came from British possessions in the East. In 1847, about 4 '5 tons were imported; in 1848, 506 tons; in 1849, 407 tons; in 1850, 522 tons. The price of safflower varies from £1 to £8 per cwt., according to quality. That from Bombay is least esteemed, fetching only 20s. to 30s. The annual quantity of safflower, according to Dr. Taylor, exported from the district of Dacca for eight years ending with 1839, amounted to 4,000 maunds, or about 149 tons. The exports through the Calcutta Custom House are occasionally large: in 1824-25 there were about 316 tons; 8,500 Indian maunds were shipped from Calcutta in each of the years 1841 and 1842. The prices in the Liverpool market, in January 1853, were for Bengal, good and fine, £6 to £7 10s. per cwt.; middling, £4 to £4 10s.; inferior and ordinary, £2 10s. to £3.—*Simmonds.*

At the Madras Exhibition of 1855, four specimens of the powder were exhibited from Cuddapah, Chittledroog and Madura, and several packets of the seeds were sent from other districts. The dried florets of "*Carthamus tinctorius*" yield a very beautiful colouring matter, which attaches itself without a mordant. In Madras it is chiefly used for colouring cotton, and produces various shades of pink, rose, crimson, scarlet, &c. In Bangalore, silk is dyed with it, but the dye is very fugitive, and will not bear washing. An alkaline extract precipitated by an acid (Lime juice is commonly used) will give a fine rose colour either to silk or cotton. The colouring matter is not suitable to wool. The coosum is cultivated extensively throughout the Ceded Districts, &c, the seed yielding an oil, and the flower a dye. The flower is gathered and rubbed down into a powder, and sold in this state. When used for dyeing it is put in a cloth and washed in cold water for a long time, to remove a yellow colouring matter; it is then boiled and yields the Pink dyeing liquid. The Chinese safflower is worth four times the amount of the Indian article (Professor Solly), and the loss from careless drying and preparation has too often been set down to the "nature of the article."—*M. E. J. R.* According to Tomlinson, *Safflower* is the dried flowers of *Carthamus tinctorius*, the chemical principles of which are given under Carthamus. It is an annual composite plant, cultivated in India, Egypt, Spain, and the Levant, &c. on account of its dyeing properties. The flowers are the only parts used in dyeing: these yield two sorts of colouring matter; the first yellow, and of little value; the second, a pink of great delicacy and

beauty, but not very permanent. The yellow colour of safflower is soluble in water, the pink is resinous in its nature, and is best dissolved by the fixed alkalies. The flowers of the carthamus are gathered, placed in a bag, and trodden under water to get rid of the yellow colour. They are then placed in a trough with soda, in the proportion of 6 lbs. to 120 lbs. of carthamus. After soaking for a time, the contents of the trough are transferred to another, having a perforated bottom, but lined with a finely-woven cloth. This perforated trough is placed over an unperforated empty one, and water is poured through the upper one. This carries with it a large amount of the colouring matter released by the alkali. When the lower trough is full the bath is placed over another trough. A little more alkali is added and fresh water, until the latter runs through without carrying any more colouring matter. Lemon juice is added to the dye stuff in the troughs, and raises the colour to a bright cherry-red. silk, in hanks, is then immersed and turned round skein-sticks in the bath as long as it will take up any colour. It is then dried, and if the colour be not deep enough, it is passed through another bath of similar strength A final brightening is given by turning the silk round the skein-sticks 7 or 8 times in warm water with lemon-juice, in the proportion of half a pint to each pailful of water. This colour will not bear the action of soap, nor will it long withstand exposure to the sun and air; it is chiefly employed on silk for imitating the fine dye of the French called *ponceau*. For *ponceau*, or flame-colour, the silk is first boiled, and then receives a slight foundation of annotto; but it must not be alumed. Safflower is a costly dye: it is chosen in flakes of a bright pink colour; that in powder, dark-coloured, or oily, is of inferior quality. The beauty of the colour, in its purest form, has caused it to be employed in the manufacture of *rouge*. The preparation of rouge from cochineal is described under CARMINE. The delicate and beautful rouge, known as *rouge vegetale*, is nothing more than the colour of safflower which has been extracted by means of crystallized soda, precipitated by citric acid, then slowly dried, and ground up with the purest talc. Dr. Ure's account of the process of rouge-making from safflower is as follows: "The flowers, after being washed with pure water till it comes off colourless, are dried, pulverized, and digested with a weak solution of crystals of soda, which assumes thereby a yellow colour. Into this liquor a quantity of finely carded white cotton wool is plunged, and then so much lemon-juice or pure vinegar is added as to supersaturate the soda. The colouring matter is disengaged, and falls down in an impalpable powder upon the cotton filaments. The cotton, after being washed in cold water, to remove some yellow colouring particles, is to be treated with a fresh solution of carbonate of soda, which takes up the red colouring matter in a state of purity. Before precipitating this pigment a second time by the acid of lemons, some soft powdered talc should be laid in the bottom of the vessel for the purpose of absorbing the fine rouge, in proportion as it is separated from the carbonate of soda, which now holds it dissolved. The coloured mixture must be finally triturated with a few drops of olive-oil in order to make it smooth and marrowy. Upon the fineness of the talc, and the proportion of the safflower precipitate which it contains, depends the beauty and value of the cosmetic. The rouge of the above second precipitation is received sometimes upon bits of fine-twisted woollen stuff, called *crepons*, which ladies rub upon their cheeks"—*Tomlinson*. See CARTHAMUS.

(7287) SAFFLOWER OIL. CARTHAMUS TINCTORIUS.

Chendoorookoo yennai, TAM.	Kurrur or Coosum ka tael, HIND.
Koosumba, noonay, TEL.	

A light yellow clear oil is obtained from the seeds of the plant, yielding the well known dye. It grows plentifully in Mysore and Tinnevelly. In Mysore and Bellary, it costs about Rs 2-8-0 per maund, and is used for lamps, culinary and other purposes.—*M. E. J. R.*

(7288) SAFFLOWER SEED.

Kurdeh, GUZ. and HIND.

The seed of the *Carthamus tinctorius* is triangular shaped, of a whitish yellow colour, and affords an oil used by the natives of India for culinary purposes. Kurdeh has of late been exported from Bombay to England and France as an "oil seed."—*Faulkner*.

(7289) SAFFRON. CROCUS SATIVUS.

Zaifran, ARAB.	Abeer, Kurkam, Kurkoom, Zaifran, PERS.

Safaron, MAL.	

Crocus sativus, saffron, is a native of Asia Minor, naturalized in England, France, and many other parts of Europe, and cultivated in Persia and Cashmere. The saffron of commerce consists of the dried stigmata of the flower. These are picked out, dried on paper either in a kiln or by the sun. If compressed into cakes it is accordingly called *cake* saffron; *hay* saffron is what is usually met with. The *hay* saffron consists of the stigmas, each

about an inch and a half long, brown-red, the upper part flattened, widened, and cleft; the lower, hair-like and yellowish. The odour is fragrant, taste bitter but agreeable. Saffron tinges the saliva yellow. Mr. Pereira informs us that one grain of good saffron contains the stigmata and styles of nine flowers, so that one ounce of saffron, is equal to 4,320 flowers. *Cake* saffron as now met with, contains none of the real article, being prepared from the florets of the safflower (see CARTHAMUS) made into a paste with gum water.—*O'Shaughnessy, p.* 654. Dr. Honigberger, p. 263, mentions that Crocus sativus is monopolized by the Cashmerean government and that the Hakims of the Punjab use saffron in melancholy, typhus fever, enlargement of the liver, and retention of urine. It is now imported into India both from Persia and Cashmere, but into the North western parts of India from the latter only. Dr. Falconer, who visited Cashmere is of opinion that Saffron could be successfully cultivated in the Himalayas, at heights varying from six thousand to six thousand five hundred feet above the sea, and that if it were once brought into the market, the demand for it would be almost unlimited.—*Rhode M.S.S.* Saffron consists of the pistils of the *Crocus sativus*, a bulbous plant, found in various parts of the South of Europe and Asia, and cultivated to a small extent in Cambridgeshire. The pistils are generally dried, and compressed into firm cakes or masses, termed in India *Rootla saffron*; but the finest called *Hay saffron*, consists of the pistils merely dried. When good, saffron has a sweetish, penetrating, diffusive odour; a warm, pungent, bitterish taste; and a rich deep orange colour. It is used in medicine, as a colouring substance, and in domestic cookery. Saffron is brought to India from England, the sea ports of the Red Sea, Persia, and Cashmere.—*Faulkner*. Ainslie tells us that the vytians prescribe this article in nervous affections attended with vertigo, and where there appears to be an approach to apoplexy, by accumulation of blood in the head. They also believe it to possess considerable virtue in Melancholia, Hysteric depressions, and Kistnah Dashum (Typhus Fever), in which last they suppose it to act as a cordial and restorative. To women, soon after the pains of childbirth are over, an infusion of saffron is frequently administered by the Tamool midwives to prevent fever, to support the animal spirits; and gently to assist in carrying off the lochia. This medicine is besides used by the Indian Practitioners as an external application in Ophthalmia when mixed with a small quantity of ponnded Kadukai (Chebulic Myrobolan) and lime juice and applied round the eye, but close to it. The Arabians class it amongst their Mosebetal (Hypnotica) Mokewyatdit (Cardiaca) and Mufettehat (Deobstruentia).—*Ainslies' Mat. Med. page* 38. According to Tomlinson, *Saffron* consists of the stigmata of the flowers of a perennial bulbous plant (*Crocus sativus.*),once extensively cultivated at Saffron Walden in Essex, and still fostered in some parts of Cambridgeshire. From this small portion of the flower is obtained a rich yellow-red colour, which, when dried and pure, is of a scarlet hue. Saffron is imported into Britain, from Sicily, France, and Spain, but the foreign product is not so much esteemed as the English. The use of saffron is, however, diminishing. It is employed as a seasoning in cookery: also to colour confectionary, liqueurs, varnishes, and sometimes cheese and butter. It is used to a small extent by painters and dyers. It was formerly much used in medicine as a carminative, antispasmodic and emmenagogue, and it is still occasionally employed to promote the eruption of certain diseases of the skin. On the same principle it is given to birds to assist their moulting. Dr. Lindley describes the colouring ingredient of this plant as "a peculiar principle to which the name of Polychroite has been given; it possesses the properties of being totally destroyed by the action of the solar rays, colouring in small quantity a large body of water, and of forming blue or green tints when treated with sulphuric and nitric acid, or with sulphate of iron. In moderate doses, this substance stimulates the stomach, and in large quantities, excites the vascular system. Moreover it seems to have a specific influence on the cerebro-spinal system, as it affects, it is said, the mental faculties, a result which De Candolle considers analogous to that produced by the petals of certain odorous flowers." Saffron is known in commerce as a kind of fibrous cake. This should be moderately moist, close, tough, and compact, the smell sweet and penetrating, the taste warm, pungent, and somewhat bitter.—*Tomlinson.*

(7290) SAGAPENUM.

Sukbennj, ARAB.	Sagapeno, IT.
Sagapenum, FR.	Sagafioon, PERS.
Sagapenummi, GER.	Kundel, SANS.
Sugbennj, GUZ. HIND.	

A concrete gum resin, supposed to be a kind of assafœtida (*Ferula Persica*). It is found in masses formed of soft, adhesive fragments, the size of the thumb or more, somewhat transparent, reddish yellow exterually, pale within, of a waxy or brittle consistence, often mixed with impurities and seeds. Its odour resembles that of garlic and assafœtida, its taste is hot, nauseous, and rather bitter. It is sometimes adulterated with B'dellium (*Vern*,Googul), and other similar gums. Its medicinal uses are the same as those of assafœtida, but it is considered less energetic, and is but little employed. It is obtained from Smyrna, Alexandria, &c.—*O'Shaughnessy.*

(7291) SAGE. A perennial, native of the South of Europe; it grows in all the gardens,

and is propagated by seeds, layers, and slips, without any difficulty. It is used for seasoning.

(7292) SAGE, BENGAL.

Murtoo, BENG.

Leaves and herb of Meriandra Bengalensis.—*Ben. p.* 223.

(7293) SAGERETIA, a genus of Plants belonging to the natural order of *Rhamnaceæ*, formed, by M. A. Brongniart, of old species of *Zizyphus* and of *Rhamnus*, and named after M. Sageret, a French vegetable physiologist. The species are found in both South and North America, Java, China, and in India along the foot of the Himalayas. The only species which requires particular notice is *S. ageretia thee'sans* which is remarkable as being employed as a substitute for tea, even in China, where the poor are described by Osbeck as making use of the leaves in the same manner as those of the true tea, and for which it makes a good substitute from its astringency and fragrance.—*Eng. Cyc.*

(7294) SAGIG. The name given by the Bisayas, to a variety of the Manilla Hemp.—*Royle, Fib. Plants.*

(7295) SAGITTARIA SAGITTIFOLIA. The arrowhead, is one of the handsomest of British aquatic plants, whether as regards the elegant spear leaved canes of glossiest green, or the flower spikes rising in pyramidal form from the surface of the water. This plant is extensively cultivated among the Chinese not for its beauty but for the sake of its bulb, which fixes itself in the solid earth below the mud and constitutes an article of food.—*Art Jour. page* 108, *April* 1857.

(7296) SAGO.

Sagu, BALI.	Sagu, JAV.
Sagoodana, BENG.	Sagu, MAL.
Sekuhme, CHIN.	Showarisee, TAM.
Sagoo, Sagoo-chawl, GUZ. HIND.	Zowbeeum. TEL.

General Remarks—Sago, and starchy matter allied to it, is obtained from many palms. It is contained in the cellular tissue of the stem, and is separated by bruising and elutriation. From the soft stem of *Cycas circinalis*, a kind of sago is produced in the East and West Indies. The finest is, however, procured from the stems of *Sagus laevis* (*S inermis*, of Roxburgh), a native of Borneo and Sumatra; and *Arenga saccharifera*, or *Gomutus saccharifera*, of Rumphius. The *Saguerus Rumphii*, or *Metroxylon sagus*, which is found in the Eastern Islands of the Indian Ocean, yields a feculent matter. After the starchy substance is washed out of the stems of these palms, it is then granulated so as to form sago. The last-mentioned palm also furnishes a large supply of sugar. Sago as well as sugar, and a kind of palm wine, are procured from *Caryota urens*. In China, sago is obtained from *Raphis flabelliformis*, a dwarfish palm; and some sago is made from it for native use in Travancore, Mysore, and Wynaad, in the East Indies.

The trunk of the sago palm, *Metroxylon sagus*. is five or six feet round, and it grows to the height of about 20 feet. It can only be propagated by seed It flourishes best in bogs and swampy marshes; a good plantation being often a bog, knee deep. The pith producing the sago is seldom of use till the tree is fourteen or fifteen years old; and the tree does not live longer than thirty years. Mr. Crawfurd says there are four varieties of this palm; the cultivated, the wild, one distinguished by long spines on the branches, and a fourth destitute of these spines, and called by the natives female sago. This and the cultivated species afford the best farina; the spiny variety, which has a slender trunk, and the wild tree, yield but an inferior quality of sago.

The farinaceous matter afforded by each plant is very considerable, 500 lbs being a frequent quantity, while 300 lbs. may be taken as the common average produce of each tree. Supposing the plants set at a distance of ten feet apart, an acre would contain 435 trees, which, on coming to maturity in fifteen years, would yield at the before-mentioned rate 120,500 lbs. annually of farinaceous matter. The sago meal, in its raw state, will keep good about a month. The Malays and natives of the Eastern Islands, with whom it forms the chief article of sustenance, partially bake it in earthenware moulds into small hard cakes, which will keep for a considerable time. In Java the word "saga" signifies bread.

The sago palm (*Metroxylon sagus*) is one of the smallest of its tribe, seldom reaching to more than 30 feet in height, and grows only in a region extending west to Celebes and Borneo, north to Mindanao, south to Timor, and east to Papua. Ceram is its chief seat, and there large forests of it are found. The edible farina is the central pith, which varies considerably in different trees, and as to the time required for its attaining proper maturity. It is eaten by the natives in the form of porridge. A farina of an inferior kind is supplied by the Gomuti palm, another tree peculiar to the Eastern Archipelago growing in the valleys of hilly tracts. Perhaps all of these trees contribute to produce the ordinary sagos of commerce, for there are several kinds. Planche, in an excellent memoir on the sagos, has described six species, which he distinguishes by the names of the places from which they come. Preferring to classify them according to their characters, M. Mayet distinguishes only three species. The *first* he denominates.

Uncut sago, which comes from different parts, and varies much in color. It comprehends—1*st*, *Maldivian sago* of Planche, in sphe-

rical globules, of two or three millimetres in diameter, translucid, of an unequal pinkish white color, very hard and insipid. *2nd. New Guinea* sago, of Planche, in rather smaller globules, of a bright red color on one side, and white on the other. *3rd. Grey sago of* the Moluccas or brown sago of the English, of unequal globules, from one to three millimetres in diameter, opaque, of a dull grey color on one side, and whitish on the other. This grey color probably raises from long keeping and humidity. *4th. Large grey sago* of the Moluccas, exactly resembling No. 3, only that the globules are from four to eight millimetres in diameter. *5th. Fine white sago* of the Moluccas; entirely resembling No. 3, only that it is purely white, owing to the complete edulcoration of the fecula of which it is made. Whatever may be the places of origin of these sagos, they all possess the following characters—Rounded globules, generally spherical, all isolated, very hard, elastic, and difficult to break or powder. The globules put into water, generally swell to twice their original size, but do not adhere together.

Second sago.—This species corresponds with the pinkish sago of the Moluccas of Planche. It is in very small globules, less regular than those of the "first sago," and sometimes stuck together to the number of two or three. Soaked in water, it swells to double its volume.

Third Sago.—Tapioca sago.—This name has been applied to a species of sago now abundant in commerce, because it bears the same relation to the ancient or first sago, and even to the preceding sago, that tapioca bears to "Moussache," which is the fecula of the manioc, *Janipha manihot* (*Manihot utilissima*). Whilst the two preceding species of sago, whatever may have been stated to the contrary, have been neither baked nor submitted to any heating process, as is proved by the perfect state of nearly all their grains of fecula, their species has been subjected to the action of heat while in a state of a moist paste. This sago is not in spherical globules, like the two preceding species, or at least there are but few of the globules of that form; it is rather in the form of very small irregular tubercular masses, formed by the adherence of different numbers of primary globules. The facility with which this sago swells and is divided by water, has occasioned it to be preferred as an article of food to the ancient sago. It has been described by Planche under the name of the white sago of the Moluccas, and by Dr. Pereira under the name of pearl sago.

Bennet, in his work on "Ceylon and its Capabilities," (1843), states that sago is procured from the granulated pith of the talipot palm, *Corypha umbraculifera.*

The *Sagus Rumphii*, Wildenow, and *S. farinifera*, Gaertner.—Before maturity, and previous to the formation of the fruit, the stem consists of a thin hard wall, about two inches thick, and of an enormous volume of tissue (commonly termed the *medulla* or *pith*), from which the farina or sago is obtained. As the fruit forms, the farinaceous medulla disappears, and when the tree attains full maturity, the stem is no more than a hollow shell. Sago occurs in commerce in two states, pulverulent and granulated. 1. The meal or flour is imported in the form of a fine amylaceous powder. It is whitish, with a buffy or reddish tint. Its odor is faint, but somewhat unpleasant and musty. 2. Granulated sago is of two kinds, pearl and common brown. The former occurs in small hard grains, not exceeding in size that of a pin's head, inodorous, and having little taste. They have a brownish or pinkish yellow tint, and are somewhat translucent. By the aid of a solution of chloride of lime they can be bleached, and rendered perfectly white. The dealers, it is said, pay £7 per ton for bleaching it. Common sago occurs in larger grains, about the size of pearl barley, which are brownish white.

Sago is an article of exportation to Europe, and is also shipped to India, principally Bengal, and to China. It is in its granulated form that it is usually sent abroad. The best sago is the produce of Siak, on the north coast of Sumatra. This is of a light brown color, the grains large, and not easily broken. The sago of Borneo is the next in value; it is whiter, but more friable. The produce of the Moluccas, though greatest in quantity, is of the smallest estimation. The cost of granulated sago, from the hands of the grower or producer, was, according to Mr. Crawfurd, only a dollar a picul. It fetches in the London market—common pearl, 20s. to 26s. the cwt., sago flour, 20s. the cwt. The Chinese of Malacca and Singapore have invented a process by which they refine sago, so as to give it a fine pearly lustre, and it is from thence we now principally derive our supplies of this article. The exports from Singapore in 1847 exceeded 6½ million pounds, but are now much larger.

Manufacture.—The following is a description of the manufacture of this important article of commerce—The tree being cut down, the exterior bark is removed, and the heart, or pith of the palm, a soft, white, spongy and mealy substance is gathered; and for the purposes of distant transportation, it is put into conical bags, made of plantain leaves, and neatly tied up. In that state it is called by the Malays *Saugoo tampin*, or bundles of sago; each bundle weighs about 30 lbs. On its arrival at Singapore it is purchased by the Chinese manufacturers of sago, and is thus treated:—Upon being carried to the manufactory, the plantain-leaf covering is removed, and the raw sago, imparting a strong acid odour, is bruised, and is put into large tubs of cold spring water, where

it undergoes a process of purification by being stirred, suffered to repose, and again re-stirred in newly-introduced water. When well purified thus, it is taken out of the tubs by means of small vessels; and being mixed with a great deal of water, the liquid is gently poured upon a large and slightly inclined trough, about ten inches in height and width; and in the descent towards the depressed end, the sago is deposited in the bottom of the trough, whilst the water flows into another large tub, where what may remain of sago is finally deposited. As the strata of deposited sago increases in the trough, small pieces of slates are adjusted to its lower end to prevent the escape of the substance. When by this pouring process the trough becomes quite full of sago, it is then removed to make room for a fresh one, whilst the former one is put out into the air, under cover, for a short time; and on its being well dried, the sago within is cut into square pieces and taken out to be thoroughly dried, under cover, to protect it from the sun. It has then lost the acid smell already noticed, and has become quite white. After one day's drying thus, it is taken into what may be called the manufactory, a long shed, open in front and on one side, and closed at the other and in the rear. Here the lumps of sago are broken up, and are reduced into an impalpable flour, which is passed through a sieve. The lumps which are retained by the sieve are put back to be re-bruised, whilst that portion which has passed is collected, and is placed in a long cloth bag, the gathered ends of which, like those of a hammock, are attached to a pole, which pole being suspended to a beam of the building by a rope, one end of it is sharply thrown forward with a particular jerk, by means of which the sago within is shortly granulated very fine, and becomes what is technically termed "pearled." It is then taken out and put into iron vessels, called *quallies*, for the purpose of being dried. These quallies are small elliptical pans, and resemble in form the sugar coppers of the West Indies, and would each hold about five gallons of fluid. They are set a little inclining, and in a range, over a line of furnaces, each one having its own fire. Before putting in the sago to be dried, a cloth, which contains a small quantity of hog's-lard, or some oily substance, is hastily passed into the qually, and the sago is equally quickly put into it, and a Chinese laborer who attends it, commences stirring it with a *pallit*, and thus continues his labour during the few minutes necessary to expel the moisture contained in the substance. Thus each qually, containing about ten pounds of sago, requires the attendance of a man. The sago, on being taken off the fire, is spread out to cool on large tables, after which it is fit to be packed in boxes, or put into bags for shipment; and is known in commerce under the name of "pearl sago." Thus the labor of fifteen or twenty men is required to do that which, with the aid of simple machinery, might be done much better by three or four laborers. A water-wheel would both work a stirring machine and cause an inclined cylinder to revolve over a fire, for the purpose of drying the sago, in the manner used for corn, meal, and flour in America, or for roasting coffee and chicory in England. But the Chinese have no idea of substituting artificial means, when manual ones are obtainable.

Singapore.—A considerable quantity of sago is exported from Singapore in the state of flour. The whole quantity made and exported there exceeds, on the average, 2,500 tons annually. The quantity shipped from this entrepot is shown by the annexed returns, nearly all of which was grown and manufactured in the settlement. The estimated value for export is set down at 14s. per picul of 1¼ cwt.

—*Simmonds.*

From the above, it will be observed that sago, and the allied starches which receive its name, is now an extensive article of diet, contributing largely to the food of the nursery, the diets of the invalid and the delicacies of the tables of the rich. It is contained in the cellular tissue of the stem of many trees, principally palms, from which it is separated by bruising and washing. In the language of the Papua Islands, Sago signifies bread, and in many countries, this vegetable product consti-

tutes a large part of the food of the people. And the extent to which it has latterly been brought into general use, may be judged of by mentioning that the imports into England have increased from 9,644 cwts. in 1826 to 100,000 cwts. on the average of the four years ending 1852. In commerce, sago is met with in the form of sago meal, and as pearl sago, the latter being the usual form it is seen in Europe from the meal not keeping. In the process of manufacture, the wood is split into billets, the soft interior extracted pounded and thrown into water, the water is then drained off the pulpy mass, when the starch comes away with it, and being allowed to settle, is afterwards prepared and purified by successive washings. This is the "crude" or "raw" "sago," or "sago meal," of commerce. The *Process* employed in manufacturing the pearl Sago, is supposed to have been invented by the Chinese. When the raw Sago has been several times washed and strained through cloth, the masses which collect at the bottom of the vessels are collected, broken into pieces, and placed upon platforms in the sun to dry, being broken into still smaller pieces as the drying proceeds. When sufficiently dry, they are powdered and sifted through sieves made of the midrib of the cocoa nut palm, it is then put into a bag suspended from the roof and granulated by frequent shaking. After this it is dried in iron pans over the fire.

Sources of Sago.—The time for collecting the Sago, is just before the tree flowers, which it generally does when seven or eight years old. The best sago of commerce is obtained from two species of Metroxylon, viz. M. Rumphii, Mart: and M. læve, Mart: which inhabit the islands of the Indian Archipelago, and form extensive forests almost exclusively composed of their own kind, these two trees both grow in marshy spots. This is known as the true sago palm. A sago is also produced abundantly from one of the date species, the *Phœnix farinifera*, q. v. The Calamusagus laciniosus, of Griffiths, is supposed also to yield it, but that known as "Mergui sago" is manufactured from the *Tacca pennatifida*. A sago was also exhibited in the Madras Exhibition of 1855, made from the Cycas circinalis. The pith of Caryota urens is much used as *Sago meal*, in Canara when fresh, and deserves attention.—*M. E. J. R.* Sago is obtained in Cochin from a palm called koota pana, and sells there for 2 annas a pound, and in Cochin, the date palm flour and seed is called Eenthalkurroo. Assistant Surgeon J. Pringle, M. D., Civil Surgeon, Cochin, in a letter to the Editor, Cochin, 19th October 1850, sent specimens of Sago manufactured in the immediate neighbourhood of Cochin, the shipping port, as also throughout the country in the vicinity of the backwater, on which there is excellent water carriage to the sea coast. The best sago is made, there, from October to June, as in its preparation bright sunshine is required to mature the operation. The 1st sort may be delivered on the sea coast at Rs. 4½ per maund (25 lbs.), the 2d sort at Rs. 2¼ per maund.—*M. C. C.* Sago is made in Malabar from the pith of the Taliput palm. As with the true Sago palm, a farina is prepared from the medullary matter of the Gomuti, *the Arctenga saccharifera*: in Java, indeed, this palm is the only source of Sago, which is used in considerable quantity in the western and poorer districts of the island and is offered for sale in all the markets. It is smaller in quantity than in the pith of the true Sago-tree, more difficult to extract and inferior in quality: possessing a certain peculiar flavour from which the farina of the true Sago is free. Some trees will produce five or six female spadices, before yielding a single male one, such trees are considered unprofitable by the toddy collectors, but in this case, it is said that they yield Sago equal in quality, though not in quantity, to the Cycas circinalis, from which, both in the East and West Indies a kind of Sago is procured. One tree yielded about 150 lbs. of good Sago meal. The pith or farinaceous part of the trunk of old trees, of the Caryota urens or kittul palm is manufactured into Sago, equal to the best farina, being highly nutritious: It is said, indeed, to be equal to that of the true Sago palm. In China, Sago is obtained from Raphis flabelliformis, one of dwarfish genus of palms, a native of the island of Liu-kiu and Southern China, and, also, on the authority of Simmonds p. 314, in Travancore, Mysore, and the Wynaad. A farina is prepared in Brazil from the inside of the trunk of the "Carnauba," *Copernica cerifera*, of the Brazilians. The pithy portion of the trunk of the Gebang palm, *Corypha Gebanga*, Blume, yields a sort of Sago, as also that of the Sabal Adansonii, and the Sago palm of New Ireland.

The Cycas circinalis before alluded to, belongs to the *Cycadaceæ*, a tribe of plants possessing nearly equal affinity with palms and tree ferns. Its genera are natives of the tropics and the temperate parts of America and Asia, all of them contain a starch and it is separated from the pith of many and employed as an article of diet. *The Encephalartos* is called "Caffir Bread." The seeds of *Dion edule*, in Mexico, yield starch and in the Bahamas and other West Indian Islands, a Sago is obtained from a species of Zamia. In the Moluccas, from *Cycas Circinalis*, and in Japan from C. revoluta.—*Seeman.*

"*Ipuruma*," is the Guiana name given to a Sago like flour formed from the medullary portion of the trunk of the *Mauritia flexuosa*. It was tried by Humboldt, who described it as very agreeable to the taste, resembling rather Cassava Bread, than the sago of India. It is said to yield its sago in most abundance if the male

tree be cut down just before the flowers appear. The "red" or netted hammock of the native tribes of the Amazon, are made from string manufactured from the dried leaves of this plant.

The "Papunha," *Guilielma* species, of Brazil produces a farinaceous fruit. In various countries of Europe, millet, *Panicum muliaceum* and *P. frumentaceum* is used as a substitute for sago and is considered excellent.—*Seeman. Simmonds.*

Sago of Mergui, Sago may be seen in every bazar in the Tenasserim Provinces, but it is not generally known what plant produces it, many having the erroneous impression that it is made from manihot. It is the produce of an indigenous plant abounding along the sea shores, the islands, and especially at Mergui—a species of tacea, the same plant that is common in the South Sea Islands, whose tubers there supply to the inhabitants the place of bread. Considerable quantities of sago are made at Mergui, yet Lindley in his Medical Botany, makes no reference to tacca as yielding sago.—*Mason.*

Archipelago.—Crawfurd tells us that in the *Eastern Archipelago*, there are supposed to be five palms producing this article, of which the most frequently cultivated are the *Metroxylon sago*, Syn. *Sagus konigii*, *Rambaya* Malay: and the *Sagus lævis*, *Bamban*, Malay. Sago trees are found in every part of the Malayan Archipelago and Philippines, as far as Mindano, wherever there is a genial soil for them, and this soil consists of a marsh or bog, composed of decayed land and vegetables, near the sea but excluding tidal action. They are most abundant in the eastern parts of the Malay Archipelago at the Moluccas and neighbouring islands, with New Guinea and Borneo, and, in the Philippines, Mindano. All these palms yield an immense quantity of farina, the wood being a mere shell containing a mass of medulla, and the Sago from them is more or less the food of the inhabitants of the Archipelago. The Sagos propagate by lateral shoots, as well as by seeds, and only produce fruit once, after which they die. From the first of their properties, a sago plantation once formed is perpetual. The trees are cultivated in small patches, and a man and his family can manage a plantation of about 400 trees, in a space of 100 square fathoms. The trees are cut down immediately before bearing fruit, which is usual about the age of 15 years. When a plantation has once arrived at maturity there will be a constant harvest. The sago tree when cut down and the top severed from it, is a cylinder about 20 inches in diameter and from 15 to 20 feet in height. Assuming this to be the average, the contents will be nearly 26 bushels, and allowing one half for woody fibre, there will remain 13 bushels of starch, which will give about 700 pounds for each tree, or 12½ bushels. It may give some idea of the enormous rate of this produce, if it be considered that three trees yield more nutritive matter than an acre of wheat and six trees yield more than an acre of potatoes. An acre of sago, if cut down at one harvest, will yield 5220 bushels, or as much as 163 acres of wheat, so that according as we allow 7 or 15 years for the growth of a tree, an acre of sago is equal in annual produce to 23 or to 10 acres of wheat. Up till 1814 the Archipelago used to export small quantities of the granulated form of Sago, of a dirty brown colour, but about the time when the trade with Europe was first thrown open, the Chinese of Malacca began to prepare a much superior article known in commerce under the name of pearl sago. Of this and sago flour, or the ungranulated starch, Singapore is at present the chief place of manufacture and principal mart, the Chinese being the sole manufacturers, and the raw material being brought from various neighbouring countries, but chiefly from the north-western coast of Borneo and the north Eastern of Sumatra, with its adjacent islands from Siak to Jurdagiri In the year 1847-48, the quantity of Sago exported from Singapore was about 80,000 cwt, worth on the spot about £45,000.—*Crawfurd, p.* 372.

China.—Sago is brought to China to some extent in native vessels and is said to be the produce of the *Metroxylon sagus*, a species of palm, about 30 feet high and 18 inches in diameter. But it is not fit to make sago from until it has attained maturity, at which time the trunk is hollow. This tree grows in Sumatra and on the western side of Borneo. When cut down, the medullary part of the trunk is scraped out and reduced to powder, and the filaments separated by washing. The meal is cooked by baking. It is made ready for sale by the natives by sewing the leaves of the tree into a sort of bag, seven of which are about equal to a pecul; all the sago tamping, as these bags are called, is brought to Singapore, where the Chinese have manufactories for refining and granulating it. This is done by mixing it with pure water, and rubbing the paste into little grains. When well cured, it has a pearly lustre, is slightly reddish and dissolves in hot water into a fine jelly. There are numerous manufactories in Singapore for making sago, from whence many thousands of peculs are annually exported, principally to England. Its price in China is $ 3 to $ 4 per pecul —*Morrison.*

(7297) SAGUS, OR SAGUERUS, a genus of Plants belonging to the family of Palms. The leaves are pinnated; the flowers monœcious; the spadix branched, without any common spathe, but with numerous partial ones; the fruit hard, shining, its surface divided into numerous rhomboidal spaces. The species are natives of the islands of the Indian Archipelago, and yield sago.—*Eng. Cyc.*

(7298) SAGUS LÆVIS. Sago Tree.
Rambiya, Malay.

This is a native of Sumatra and the Moluccas. The stem is as thick as that of the cocoa-nut tree, which is from 15 to 20 years in attaining maturity.—*O'Shaughnessy, page* 640. Sagus, lævis, the True Sago-Palm, has the petioles and spathes unarmed. This palm furnishes most of the sago sent to Europe.—*Eng. Cyc.*

(7299) SAGUS RUMPHII. Sagus Rumphii, *Willd.* E. the *Sagus spinosus* of Rumph. Herb. Amb. i. p. 75, has the petioles and spathes guarded by strong prickles. According to Martin, the sago yielded by this plant is used principally in India, and seldom exported.—*Eng. Cyc.* It is made officinal in the London Pharmacopœia as the plant yielding Sago, which is described as *Medullæ Fœcula*; but Endogens have no proper pith. In that of Edinburgh it is said to be the Farina from the interior of the trunk of various Palms and species of Cycas. The Malays are said to prefer the Sago of this tree(*Sagus Rumphii*). Dr. Roxburgh states that the granulated Sago is made from sagus (*inermis* Roxb.) *lævis*, Jack. Blume states it to be produced by *Sagus lævis* and *S. genuina*. The *Saguerus saccharifer* also, (called likewise *S. Rumphii* and *Arenga saccharifera*,) when exhausted of its saccharine sap, yields Sago of good quality. *Caryotaurens* and *Phœnix farinifera* also yield a Sagolike farina in India. It is, therefore, difficult to select one as the sole officinal species. Sago is also said to be produced by species of Cycas, but the statement has never been properly confirmed. Some *Zamias* are said to yield one kind of Arrowroot in the West Indies. M. Planche has arranged the Sagos of commerce under six different heads, according to the places whence they are procured. M. Guibourt arranges them all under three heads. 1. Uncut Sago. 2. Seed Sago. 3. Tapioca Sago, which is the same as Pearl Sago. The unbroken grains of Sago, are more or less of an ovoid form, but most appear as if truncated or muller-shaped. An imitation of Sago is made with Potato-Starch near Paris. *Royle.* Sago is insoluble in cold water, but by long boiling becomes soft. *Saguerus* saccharifer, (Syn. Arenga saccharifera), is scarce, and only found in some of the gardens in Bombay, where it has been introduced from the Sumatra Islands. It is only grown as an exotic, and is a very beautiful species of palm, from its pinnate leaves. It is propagated by suckers from the roots of the old tree.—*Riddell.*

(7300) SAHCOTTAY OIL. From Canara, used for cutaneous diseases.—*M. E. J. R.* 1857.

(7301) SAILING FISH. Inquiries were made about two remarkable inhabitants of the waters about Malacca and Sumatra, described by Raffles; the sailing fish, called by the natives ikan layer, and the dugong, mentioned by Valentien, and so long talked of as the mermaid, but the Commodore was told by the inhabitants of Singapore that these fish had become very scarce, if not entirely extinct.—*American Expedition to Japan, p.* 155.

(7302) SAIL-LEAF. Pandanus.—On many of the Burmese boats, sails are seen made of large narrow leaves, sewed together. They are the leaves of a species of screw pine, that has a trunk like a palm, which usually grows near the sea, and is very abundant. The fruit is used by the Karens, to hackle their thread.—*Mason.*

(7303) SAKI. A pair of chop sticks was placed at each corner of every table, in the centre was an earthern pot filled with *saki* (the intoxicating drink made by the Lew Chewans) surrounded with four acorn cups, four large-coarse China cups with clumsy spoons of the same material and four tea cups of tea. Cups of tea were first handed round, these were followed by very small cups of saki, which had the taste of French liqueur.—*American Expedition to Japan, p.* 218.

(7304) SAL, or SAUL, an East Indian timber-tree, the Shorea robusta; (See 377, Dr. Wallich's Catalogue): this wood is in very general use in India for beams, rafters, and various building purposes; Saul is close-grained and heavy, of a light brown colour, not so durable but stronger and tougher than teak, and is one of the best timber-trees of India. Captain Baker considers saul to resist strains, howsoever applied, better than any other Indian timber: he says the Morung Saul is the best. The Sissoo appears to be the next in esteem, and then the teak, in respect to strength.—*Tred.*

(7305) SAL AMMONIAC, Muriate of Ammonia, Hydrochlorate of Ammonia.

Urmena, Arab.	Sale Ammoniaco. It.
Vayvagarra loonoo, Cyng.	Sal Ammoniac, Lat.
Sel Ammoniac, Fr.	Nowshadur, Pers.
Salmaik, Ger.	Naschatur, Rus.
Nowsagur Nowsadur, Guz. Hind.	Nowsadur, Sans.
	Navacharum, Tam.

Is prepared by the decomposition of the ammoniacal fluid given off during the preparation of coal gas; also, by a complicated process from bones, camel's dung, and other refuse of animal substances containing its ingredients. It is likewise found native at Etna and Vesuvius, in some of the Tuscan lakes, and in Persia, Bokhara, &c. It is met with in large cakes of a semicircular form, translucent, and colourless, with a sharp, saline, cool taste, but no smell. It is extensively employed in the arts, in the preparation of aqua-regia, in soldering some of the metals, in tinning iron and copper, in the preparation of dyes, liquid ammonia, and in various chemical manufactures. It is brought to Bombay from Calcutta, and is re-exported to the Persian and Arabian Gulfs.—*Faulkner.* Sal ammoniac, is collected in Mongolia and Ile from lakes and the vicinity of extinct volcanoes, and

blue and white vitriol, which are obtained by roasting pyrites.—*Williams' Mid. King. p.* 248. *Sal Ammoniac* is a compound of ammonia and hydrochloric acid, NH_3, H. $C._1$, now called *hydrochlora te of ammonia*, although the older term, *muriate of ammonia*, is also used. The substance from which this salt was first obtained, was the soot of camel's dung; and it was formerly produced therefrom by sublimation in large quantities, in Egypt, near the temple of Jupiter Ammon, whence the name *sal ammoniac*. It is now manufactured largely in Europe. by combining hydrochloric acid either directly or indirectly with ammonia obtained from the decomposition of animal matter. In France, bones and other animal matters are distilled in large iron retorts, for the manufacture both of animal charcoal and of sal ammoniac. Coal soot was formerly used in Great Britain as a source of this salt; but since the establishment of gas works, it has been chiefly derived from the liquor obtained during the preparation of coal gas. (See GAS.) The impure carbonate of ammonia contained in this liquor is either at once saturated with hydrochloric acid, or it is first converted into sulphate of ammonia and afterwards by decomposing it with common salt into hydrochlorate; the products being sulphate of soda and hydrochlorate of ammonia; the latter is separated by crystallization and sublimation. This salt, as obtained by sublimation. is amorphous, somewhat elastic, translucent, and colourless; and of the sp. gr. 7·45 to 1·50, but when obtained by crystalization, its form is octohedral and cubic. Its taste is sharp and saline: it has no smell; it dissolved readily in water; it does not change in dry air,and volatilizes by heat, without undergoing decomposition. It is decomposed by lime, and the fixed alkalies, with the evolution of ammoniacal gas: sulphuric acid expels hydrochloric acid gas from it. Sal ammoniac is used in the arts for a variety of purposes; as in pharmacy for making ammoniacal preparations: in tinning, to prevent the oxidation of the surface of the copper: when dissolved in nitric acid it forms the *aqua regia* of commerce, used for dissolving gold instead of nitro-hydrochloric acid. It is also used in small quantities in steam boilers, to prevent the formation of calcareous deposits.—*Tomlinson.*

(7306) SAL PRUNELLA, a term applied to nitrate of potash, fused and cast into balls resembling prunes or plums, and sometimes coloured to resemble them.—*Tomlinson.*

(7307) SALACIA, a genus of Plants belonging to the natural order *Hippocrateaceæ*, which has been so differently defined by different botanists, that it sometimes includes species found in Asia, Africa, and America. At other times, American species are referred to the genus *Tonsella*, and the African species to the genus *Calypso*, and those of India to the genus *Johnia*, the last named in compliment to Dr. John, a Danish missionary, who was one of the founders of the Botanic Garden at Tranquebar, and sent many new plants to Dr. Roxburgh. The whole are formed of species which have little beauty, but the fruit of both the species of *Johnia* is eatable.—*Eng. Cyc.* Wight gives Salacia macrosperma, 962; multiflora, 962; oblonga.; pomifera, 55; prinoides, 321; and verrucosa, 662.

(7308) SALEP. ORCHIS MASCULA. Lin.

Salib misri, ARAB & DUK.	Salamisrie, TAM.
Salep, FR.	Salep Misree, GUZ.
Salem Misree, TAM.	HIND. PERS.

The tubers of the *Orchis mascula* receive this name in works on pharmacy. They are compressed, ovoid, rather transparent, and composed chiefly of bassorine, soluble gum, and starch. Royle states that one drachm of the powdered root requires 60 drachms of boiling water to affect its solution; two drachms afford a sufficient meal for an invalid; good salep carefully prepared is in truth one of the best articles of diet a convalescent can use. In India the salep of Cashmere is reckoned the best, and is obtained chiefly at the Hurdwar fair from the Cashmere merchants. Lindley and Royle consider the plant which produces this salep to be an *Eulophia* not an *Orchis*. This substance, from the peculiar shape of the tubera, has gained immense, but most unmerited celebrity as an aphrodisiac remedy. The same circumstance has given the plant its name both in the Greek and Arabic language.—*O'Shaughnessy, page* 653. At the Madras Exhibition of 1855, there were three samples of "Salep misree" contributed by Dr. Riddell—"one" and "two", labelled "Salep misree" from the Kunner Hills near Aurungabad—sold when green, and fresh dug up, at 2 pice per seer: "three" was from Booldanah Hills in Berar—when fresh dug is sold by the bheels at 12 seers for the Rupee. These small dried tubers of terrestrial orchids were hard, and had a horny appearance, the two first were dirty green and the third of a yellowish white color. The Salep contains a gummy principle (Bassorine) beside the large proportion of amylaceous matter, which renders it highly nutritious as a diet for invalids. Dr. Riddell's price is considerably lower than that in the bazar of Madras.—*M. E. J. R.* Although that imported from the Persian Gulf is also much esteemed, and is the sort generally met with, salep is indigenous in some parts of the Western Presidency, but for want of cultivation, the tubers are scarcely worth the trouble of procuring.—*Faulkner.* Native practitioners consider Salep as a powerful strengthener of the body, and prescribe it in conjunction with mastich and some other ingredients, in such cases as require tonics.—*Ains. Mat. Med. p.* 40. This nutritive mucilagin-

ous substance is obtained from the subterraneous succulent roots of several species of orchis, especially *Orchis mascula*, thus forming one of the few exceptions to the general rule, that orchidaceous plants, which charm and astonish by their elegant, varied, or grotesque forms are without known utility to man. Salep is a powder prepared from their dried roots ; in some cases, as in that imported from India, it is in hard clear pellucid inodorous pieces. There is not much demand for this substance, although it is considered a bland and nutritious article of diet, taken with milk, in the same way as arrowroot. The orchis which yields it thrives well in England, but is not cultivated to any extent.—*Tomlinson.*

(7309) SALICINE, a peculiar, crystallizable, bitter principle, obtained from the leaves and young bark of the poplar, willow, aspen, &c. It forms small white silky needles, and in some respects, resembles the vegeta-alkalis, cinchona, and quina, having febrifuge properties ; but it differs from them in containing no nitrogen, and not forming salts with acids. Its formula is said to be $C_{26}H_{18}O_{14}$.—*Tomlinson.*

(7310) SALICORNIA. Of this genus, Wight gives, in Icones, Salicornia brachiata, 738; *fruticosa*, 738 ; *herbacea*, 738 ; and Indica, 737.

(7311) SALICORNIA INDICA.

Jidoo Paluug, Beng.

A plant very common on such salt grounds as are inundated by the spring tides. It is especially plentiful on the coast of Coromandel, and would doubtless yield a fine and cheap carbonate of soda. But the probable value of this article as an Indian export has been much depreciated by the progress of chemical science in Europe. The purest alkali is now manufactured in England by decomposing common salt by sulphuric acid, and at the low rate of 10*l.* the ton of 30 maunds.—*Eng. Cyc.*

(7312) SALISBURIA, a genus of Plants belonging to the natural order *Taxaceæ*, named in honour of R. A. Salisbury, a modern botanist of distinction. The tree, which is the only one of the genus, has long been known by the Japanese name Gingko. The genus is characterised by having monœcious flowers. The male flowers disposed in a filiform naked catkin, without calyx or corolla ; stamens numerous ; the anthers composed of 2 cells, which are pendulous, and united only at the apex. Female flowers solitary and terminal; calyx 4-fid, or rather a cup-shaped disc, from the thickened apex of the peduncle, surrounds the base of the solitary ovule ; fruit forming a drupe, which has its base supported by a fleshy cup, with a juicy white pulp ; seed nut-like, with an osseous shell ; kernel white ; embryo axillary, dicotyledonous, radicle above.—*Eng. Cyc.*

(7313) SALISBURIA ADIANTIFOLIA, the Gingko, grows naturally in Japan, is much cultivated in China, and is found in many gardens in Europe. Fine old specimens may be seen at Kew and in the Apothecaries' Garden at Chelsea. In congenial climates it attains the size of the walnut. It is remarkable for the form of its leaves, which are wedge or fan-shaped, deeply cut in the centre or bilobed, and finely striated with veins, having some resemblance to the leaves of some species of *Adiantum*, whence it is commonly called Maiden-Hair Tree in England. The pulp of the fruit is austere tasted, but the kernel is sweet, with some degree of bitterness when raw, but agreeable as a dessert when roasted like chestnuts. They are much eaten in China. Dr. Abel says he saw the fruit exposed in the markets in China, but could not find out to what purpose it was applied.—*Eng. Cyc.* In one of his journey's, here and there, on his way Mr. Fortune met with large trees of the *Salisburia adiantifolia*, which are the largest and most striking trees in some parts of the country, —*Fortune's Wanderings, page* 248 ; In the following page, he says that the only tree which he met with of very large size in this district is the Salisburia adiantifolia, commonly called the Maiden-hair tree from the resemblance its leaves bear to a fern of that name. This is one of the plants which the Chinese are fond of dwarfing, and it is, consequently, often seen in that state in their gardens. Its fruit is sold in the markets in all Chinese towns by the name of "Pa-Hwo", and is not unlike dried almonds, only whiter, fuller, and more round. The natives seem very fond of it, although it is rarely eaten by Europeans. The weeping willow, apparently the same species as we possess in England, is also common on the sides of all the rivers and canals, as well as in the gardens of the Chinese ; and there is also a species of elm but it never attains any great size and can therefore be of little value.—*Fortune's Wandering, page* 129.

(7314) SALIX. Of this genus, Wight, in Icones, gives Salix ichnostachya, 1963; and tetrasperma, 1954. Dr. O'Shaughnessy carefully examined Salix Tetrasperma, the only willow found in lower Bengal, but could not detect in it any trace of salicine. *Salix babylonica* and *Ægyptiaca*, (Khilaf bhulkee, *Arab.* Bed mooshk, *Pers.*) occur in gardens in Upper India. Salix Lindleyana, or dwarf willow, occurs at 12,000 to 13,000 feet on the Himalayas—S. chita and rotundifolia in Kunawur ; a kind of manna, *bed-kisht*, is said to be collected from the willows in Khorasan.—(*Royle.*)—*O'Shaughnessy, page* 606.

(7315) SALIX ÆGYPTIACA.

Bed-e-mnsk. Pers.

Is cultivated at Lahore for the distillation of an aromatic water, prepared from the palms of this kind of willow, which is much used in

the hot season.—*Thirty-five years in the East by Dr. Honig. See. Vol.* I. *p.* 165. *p.* 339.

(7316) SALIX BABYLONICA. WEEPING WILLOW.

Bet Mujnee Khilaf bhulkee, Seilee Mujnoo, HIND.

Mujnoo is cultivated in gardens at Ajmeer.—*Genl. Med. Top. p.* 210.

(7317) SALIX TETRASPERMA. A peculiar species of willow is common at Rangamally in the Terai which is a singular fact, as the genus is characteristic of cold and arctic latitudes, and no species is found below 8000 feet elevation on the Sikkim mountains, where it grows on the inner Himalaya only, some kinds ascending to 16,000 feet.—*Hooker. Him. Jour. Vol.* I. *page* 400.

(7318) SALMALIA MALABARICA. SYN. BOMBAX MALABARICUM: also SALMALIA INSIGNIS. Red Cotton tree.

Poola marum, TAM. | Booraga, TEL.
Moollelavoo, CAN. |

A large common tree, flowers of a beautiful red colour, the wood light, and spongy used by Moochees in their work, but very inferior.—*M. E, J. R.* Salmalia Malabarica is common about Nelambore where it is used for building.—*McIvor.* In Tenasserim, the red cotton tree is one of the most abundant forest trees, and the silky down that envelopes the seed is used to stuff mattresses and pillows and has occasionally been made into cloth. There appear to be two species, but I can refer to the description of one only.—*Mason.*

(7319) SALPIGLOSSIS. SCROPULARINEÆ. This genus of showy plants require much care in their cultivation, the situation in which they are grown should be sheltered and partially shaded, for if exposed to the sun they become withered and die suddenly, the colours are purple, red, white, and variegated. When grown in pots, it should be frequently shifted into pots, only a little larger than the previous ones, so as to make the plants bushy, the soil should be loam mixed with sand.—*Riddell*

(7320) SAL PRUNELLA. A term applied to cakes or balls composed of fused saltpetre.

(7321) SALSOLA, a genus of plants belonging to the natural order *Chenopdiaceæ*, so named from 'salsus,' salt, in consequence of many of the species yielding kelp and barilla. The species are chiefly found on the sea-shore in temperate parts of the world, and also in hot parts of the world where the soil is saline, or where there is salt water in the vicinity. The genus is characterised by having perfect flowers; the perianth 5-cleft, persistent, enveloping the fruit with its base, and crowning it with its enlarged scariose limb; stamens 5; styles 2; embryo spiral; herbs or small shrubs, smooth or pubescent; leaves alternate or opposite, roundish seldom flat; flowers axillary and sessile.—*Eng. Cyc.*

(7322) SALSOLA INDICA.

Ella-kura, TEL.; Oomarie-keeray, TAM.

This with Salicorneæ, and others, are natives of the salt marshes and grounds near the sea, flowering the greater part of the year. The green leaves are universally eaten by all classes of natives who live near the sea, and are reckoned very wholesome. The leaves of this plant alone saved many thousand lives during the famine of 1791-2-3. *Roxb.* vol. ii. p, 63.—*O'Shaughnessy, page* 525. A small procumbent weed, with linear shaped leaves used as greens, a very pleasant vegetable.—*Jaffrey.*

(7323) SALSOLA KALI, Saltwort, so named from yielding barilla or kali, that is, alkali, is found on the coasts of Europe, and of many parts of the world, and is one of the species which is burnt for the purpose of yielding kelp and barilla.—*Eng. Cyc.* The *Salsola Kali* of Europe, and the colder parts of Asia, is mostly found on sandy shores, or arid deserts; an annual bushy plant, with stiff thorny channelled leaves. The dried plant, when reduced to ashes, yields 25 to 30 per cent. of carbonate of soda.—*O'Shaughnessy, page* 526.

(7324) SALSOLA NUDIFLORA.

Rawacada, TEL.

Is a native of salt barren lands near the sea, and flowers during the greater part of the year. The stems are perennial, many-spreading, close upon the ground, and often striking root, ramous, extremities of the branches ascending. The plant is only used for fuel, but Roxburgh believes it would doubtless yield excellent soda.—*O'Shaughnessy, page* 525. Dr. Roxburgh describes *Salsola nudiflora* as a native of salt barren lands near the sea in India, where it is gathered for fuel only; but as the taste is strongly saline, it would no doubt yield good fossil alkali; and he gave it as his opinion that this plant, with two Indian species of *Salicornia*, might be made to yield barilla sufficient to make soap and glass for the whole world.—*Eng. Cyc.*

(7325) SALSOLA SATIVA is a species found on the southern coast of Spain, where some pains are taken to extend both it and the following species by cultivation, for the purpose of yielding barilla when burnt. The crop is cut in September, and laid in small heaps to dry. These heaps are collected and burnt, forty or fifty of them, in a hole in the ground. The *Salsola sativa* of Spain is equal to last species.

(7326) SALSOLA SODA is found on the southern coast of Europe, and in the north of Africa. Merat and Delens conceive that the species which yields the soda of Alicant is a new

species, and not yet described, which they propose calling *S. Beril.* Other species are described by Forskal as yielding soda on the coasts of the Red Sea.

(7327) SALSOLA SPINESCENS. —*Wight* 1795.

(7328) SALT, MURIATE OF SODA, CHLORIDE OF SODIUM.

Melh, ARAB.	Sal, LAT.
Uyah, BALI.	Gharam, MAL.
Yen, CHIN.	Meet, MAH.
Loonoo, CYNG.	Nun, Shora, PERS.
Zout, DUT.	Sal, PORT.
Sel, FR.	Sol, RUS.
Salz, GER.	Lavana, SANS.
Nemuk, GUZ. HIND.	Sal, SP.
Sale, IT.	Ooppoo, TAM.
Uyah, JAV.	Lawanum, TEL.

Well known as a seasoner and preserver of food from the earliest ages. Two kinds are distinguished, *Rock* and *Sea* salt. When found native in immense masses, which only requires to be dug and reduced to powder, it is termed rock salt; and when obtained by the evaporation of sea-water, common or sea-salt. Sea-salt is extensively manufactured on the Sea-Coast of Madras and is exported in great quantities to the Malabar Coast, Calcutta, Penang, &c.—*Faulkner.* It is manufactured on account of the Indian Government at many places along the coast: the process is not everywhere exactly the same, but generally the sea water being raised by means of packottas is run into shallow beds or pans and evaporated: additional water being added as the evaporation goes on. The salt is raked to the side and conveyed to platforms or raised places where the salt is heaped in quantities of ten or more garce. In some places, a proportion of the salt water is obtained from wells dug near salt creaks; in others the salt water is dammed up in the mouths of rivers, where it is partially evaporated for sometime before being run into the pans. In Bengal the sea water is generally evaporated by boiling.—*Rohde M. S. S.* At the Madras Exhibition of 1855, there were fourteen specimens of common *Salt* exhibited. In one locality, the Salt formed on an extensive plain to the South after the evaporation of the water driven on by the South winds, is very white, the crystals remarkably perfect and of a large size. The Salt of the Vizagapatam coast is particularly fine. That of Vizagapatam is inferior, but at Nowpada the crystals are large and pure, and so hard do they become when stored, that, according to the officers of the Salt department, sparks of fire are elicited from the old heaps, when they are broken up for sale with a crowbar.—*M. C. C.*

(7329) SALTPETRE, NITRATE OF POTASH. NITRE. *Prismatic nitre.*

Ubkir, ARAB.	Sandawa, Mesiumentah, MAL.
Wedie Loonoo, CYNG.	Salpeter, DUT.

Yava kshra, SANS.	Nitro Salitre, SP.
Potti-loopoo, TAM. & TEL.	

A salt composed of nitric acid and potash. It may be regarded both as a natural and artificial product; being found on the surface of the soil in many parts of India, Egypt, Italy, &c. But in these and other places, all that is known in commerce is obtained by an artificial process, or by lixiviating earth that has been formed into nitre beds. From Bengal and Madras, saltpetre has been largely shipped to England; and of late years it has also formed an article of export from Bombay to England and the Continent. It is used for making gunpowder, signal-lights, nitric and sulphuric acids, in metallurgy, dyeing, and medicine. *Faulkner.*—At the Madras Exhibition of 1855, eight good samples were exhibited, the jury considered that exhibited by Mr. Ouchterlony to be the best, and awarded to him a 2d Class Medal —the next and almost equally good, being that of Mr. J. Rundall, Razole, Rajahmundry—to whom the jury awarded honorable mention. The specimens of commercial Saltpetre examined in Madras have, generally speaking, been very pure, and especially free from "*Sulphates.*" Saltpetre in Southern India, is made at Moganore and Errode. Saltpetre of a very fine quality is made at Ellore. The native name of the town is *Oopoo Ellore*, shewing that it has long been famous for this mineral at 1 Rupee the maund, very good, but they produce a twice boiled Saltpetre at 2 Rupees which is very superior. Saltpetre is found in some of the caves of Tenasserim and is imported from Rangoon.—*Mason.* Marsden referring to the saltpetre caverns in the country of *Caltoun* near the land of the *Davi* river, in Sumatra Researches, states that these caves are filled with nests of innumerable birds of the swallow kind which abound the more the further one advanced into the cave and that it was their dung forming the soil (in many places from four to six and even from fifteen to twenty feet deep) which affords the nitre. A cubic foot of this earth produced on boiling 7 pounds 14 ounces of Saltpetre and a further experiment gave one ninth more.—*Rohde M. S. S.* See POTASH, NITRATE OF.

(7330) SALVADORA INDICA. Royle, p. 319.

Jal, HIND. | Irak, also Miswak, PER.

Mahomedan tooth brush tree; leaves, *Rasuna.* Found on the banks of the Jumna, and from Delhi to Saharunpore. The leaves resemble the lanceolate senna, and are also purgative; the fruit is called *Peel* and *Pinjood*, and is said to be eatable. It is not known whether the root bark possesses the same acrid properties as in the

succeeding species. We deem both the plants highly deserving of further investigation.—*O'Shaughnessy, page* 527. *Salvadora Indica*—the tooth brush tree, grows also in the Punjab. The leaves, *Rasuna* resemble the lanceolate senna, and are purgative; the fruit is called *Peel* and *Pinjood*. The twigs of this tree are used as tooth-brushes.—*Thirty five years in the East, by Dr. Honig. p.* 339.

(7331) SALVADORA PERSICA. *Syn.* CISSUS ARBOREA, *Forskal.* Persian Salvadora.

Piloo-Kurjal, HIND.

Salvadora Persica, the Mustard-Tree of Scripture, has a succulent fruit with an aromatic smell, and tastes like garden cress. The bark of the root is extremely acrid; bruised and applied to the skin, it soon raises blisters, for which the natives of India often use it.—*Eng. Cyc.* It grows in most parts of the Circars of India, also in Arabia, and the Persian Gulf. Thrives well in every soil, and is in flower and fruit all the year round. Trunk generally crooked, from eight to ten feet high to the branches, and one foot in diameter. The bark of the root is very acrid, and if applied to the skin soon raises blisters; it promises to be a stimulant of very great power.—(*Roxb.*) It is supposed to be the mustard tree of Scripture (*Lind.*); a decoction of the bark of the stem is said to be tonic, and the red berries eatable. —*O'Shaughnessy, page* 526. It is a very common tree in Ajmeer and Marwar. The bright green of the leaves is very refreshing to the eye, as the tree grows in very barren places; it is generally semi recumbent on the ground, and affords little shade. The leaves and bark are very acrid, smelling very strongly of cresses; the freshly pounded bark of the root is an active epispastic and though not known as such to the natives of Ajmeer, Dr. Irvine employed it successfully.—*Irvine.* An excellent solid oil, of a bright green color, is obtained from Bombay, having a consistence intermediate between that of tallow and wax, fusible at about 95 degrees, and easily bleached. It has a peculiar and somewhat aromatic odour. There is some uncertainty as to the plant from which it is obtained. It was referred to the Salvadora persica, and to the Vernonia Anthelmintica, a plant common in Guzerat and the Concan Ghats.—*Simmonds.*

(7332) SALVADORACEÆ, a natural order of Monopetalous Exogenous Plants, comprising only one genus, *Salvadora.* It is characterised by possessing a superior ovary, regular flowers, single carpel, single style with a simple stigma, and a 1-celled fruit with a single seed. The position of the genus *Salvadora* has always been doubtful: by one author it has been referred to *Chenopodiaceæ*, although it has a monopetalous corolla; by others it is referred to *Myrsinaceæ*, from which it differs in the position of its stamens and the structure of the ovary and seeds. It is most nearly allied to *Plumbaginaceæ* and *Plantaginaceæ*; with the former it agrees in habit, and with the latter in the number of the parts of the flower, its membranous corolla, and simple style. They are Indian and north African plants, with eatable fruit.—*Eng. Cyc.*

(7333) SALVIA. There are very numerous species of this genus, which correspond very closely in their properties; one, the *S. amarissima* is excessively bitter.—*O'Shaughnessy, page* 488.

(7334) SALVIA BENGALENSIS. BENGAL. SAGE. Roxb. Fl. Ind. i, p. 146.

(Murtoo) BENG *Meriandra bengalensis* (Bentham). Common in Bengal and Coromandel, much stronger than the officinal sage,—a straggling shrub with a trunk often as thick as a man's arm.—*O'Sh. p.* 488. It is cultivated in European gardens at Ajmeer: the Hindoos think this a very impure plant.

(7335) SALVIA BENGALENSIS. ROTTLER.

Saya cliey, TAM.; | Yelaitie Cafoor ka paat DUK.

(7336) SALVIA COCCINEA. This, as with all this very extensive genus chiefly of extremely showy flowering plants of every variety of color, is well worthy of cultivation; the plants may all be grown from seed in any good garden soil at the commencement, or after the rains.—*Riddell.*

(7337) SALVIA GLUTINOSA, vegetates on the mountains of Cashmere, but is not used.—*Honigberger.*

(7338) SALVIA MOORCROFTIANA, is found plentifully growing in the valley of Cashmere; its seeds are officinal, both at Cashmere and Lahore.—*Thirty five years in the East by Dr. Honig. p.* 339.

(7339) SALVIA OFFICINALIS. SAGE.

Salbia HIND.

A slightly aromatic, shrubby, but dwarfish plant, of somewhat bitter and very hot, aromatic, and slightly astringent flavour. These qualities are retained on drying. It affords on distillation with water a large quantity of essential oil, containing 26 per cent, of camphor.—*O'Shaughnessy, page* 487. *Sage* is used for stuffings and flavouring various dishes: culture difficult to manage, but some of the Indian varieties might be more useful.—*Jaffrey.*

(7340) SALVINIA CUCULLATA. This curious little floating plant, related to the ferns, of the genus Salvinia is often seen on the surface of old tanks and stagnate waters in Tenasserim, —*Mason.*

(7341) SAMADERA, a genus of plants belonging to the natural order *Simarubaceæ*, which was named by Gærtner, though the origin of the name is unknown. The genus, though containing but few species, includes *Vittmannia* of Vahl and *Niota* of Lamarck. The genus is characterised by having bisexual flowers; calyx 4-5-partite: petals 4 5, much longer than the calyx;

stamens 8-10; ovaries 5-seeded, on a short stalk-like gynophore; styles. Fruit of one or more carpels, usually drupaceous. The genus is composed of trees or shrubs, with simple alternate and reticulately-veined leaves. Peduncles are axillary or terminal, pendulous when in fruit and divided at the apex into a 5-12-flowered umbel. *S. tetrapetala* is a shrub, 10 feet in height, a native of Madagascar. *S. lucida* (*Niota lucida*) is another shrub, figured by Dr. Wallich ('Pl. As. Rar.,' t. 168), from Amherst, on the coast of Martaban. *S. Indica* (*S. pentapetala* of authors) is a large tree, a native of Southern India, especially on the Malabar coast; the fruit and bark are intensely bitter, like that of the other plants of the Quassia family. Nicpa Bark, an Indian febrifuge, is obtained from this species.—*Eng. Cyc.*

(7342) SAMADERA INDICA. This tree is common throughout the Southern Concan.—*Eng. Cyc.*

(7343) SAMADERA LUCIDA. Samadera. The low grounds near the sea coast of Tenasserim are ornamented with a handsome shrub which is a species of Samadera, and bears a rather curious flower. Like the quassia of the same tribe, its leaves are most intensely bitter, and may perhaps possess the virtues of quassia. Wight says it is cultivated in the gardens about Batavia; Mr Mason has never seen it out of its native jungles on this Coast.—*Mason.*

(7344) SAMBUCUS NIGER, is unknown to the Lahore native doctors. But Sambucus adnata and S. Ebulus (Dwarf elder) are found growing in the Himalayas as well as in Cashmere. The roots of the latter, it is said, have purgative properties, and, as also the berries, are used in dropsy.—*Thirty five years in the East by Dr. Honig. p.* 340.

(7345) SAND. This name is popularly applied to any comminuted minerals, but, properly belongs to granular quartz, silica, or flint, the chief ingredient in the sands of the deserts, sea-shores, river banks and soil. Sand is produced by the disintegration of rocks, and its colour, which is generally imparted by oxide of iron, may be red, white, grey, or black. The pure colourless sands are much in request for the manufacture of glass. Sand is also used for making mortars, and for filters, and in the operation of *Casting* and *Founding*. Sand is also used in sawing and smoothing building stones and marbles, and in many other grinding and polishing operations. River and pit sand are usually sharper than sea sand, for this has been rounded by attrition. The washed scrapings of roads which have been repaired with flints furnish the sand used by stone masons *Grindstone dust* is a form of sand useful for some puposes; it cuts deeper than *Flanders brick*, which is another form in which sand is used. Grindstone dust is formed during the turning of the grindstone into form.—*Tomlinson.*

(7346) SAND BINDING PLANTS.

(7347) *Spinifex Squarrosus.* Linn. The species known to Europeans by the designation of "Ground Rattan" also called "Sea Pink," Ground Rattan. These names are both popular misnomers, the correct designation is "Spinifex" of Botanists. The Tamil name, *Ravnen mise*, i. e. Whiskers of Ravanah, is a descriptive epithet, This comes nearest to the *Sand Carex* of England in its habit of growth, creeping along horizontally, sometimes above, sometimes below the surface of the earth, emitting roots and shoots at short intervals of a few inches. It likewise possesses the advantage of being extremely tenacious of life; the shoot at every node is capable of renewing the existence of the individual as fast as destroyed, and the whole plant offers a resistance to the effects of a storm which is rarely overcome. This species would be nearly as indestructible from natural causes as Couch grass, and would speedily colonize the sand tracts spontaneously, if it were only left unmolested for a year or two.

(7348) *Ipomœa pes-caprœ*, Sweet.
Mosul Tayhe, Tam.

Goat's foot leaved *Ipomœa*, (also known as "Rabbit weed"). Perennial, creeping to a very great extent. Stems rooting at distant intervals. Leaves smooth, long petioled, two lobed, like those of *Bauhinia*, tipped with a *mucro*. Flowers large, reddish purple, very handsome. Common on the sandy beach north and south of Madras, where it is of great use in binding the loose sand, and in time rendering it sufficiently stable to bear grass. This fine creeper is equally abundant in both peninsulas, and is also a native of Mauritius, Macao, &c., occupying the place of *C. Soldanella* of the British coast, and a more striking and beautiful species of the Tropical Bind weeds is rarely seen. Rabbits, goats, and horses eat it, so do cows, but their milk is tainted. Great difficulty occurs in raising this plant in the vicinity of houses as the inhabitants tread it down, and cattle nibble the tender shoots. It naturally takes a higher position on the sand-bank than the Spinifex, and suffers less injury during a storm, but they often grow together and conjointly effect much benefit. The Spinifex arrests the drifting sand, and the Ipomœa secures what the former collects. Mr. Caddell has planted it most extensively along the Canal banks near Tranquebar.

(7349) *Canavalia obtusifolia* D. C.
Koyli avaree, Tam.

Common on the sea-shore, frequently entwined with the last named binder, is also a very useful plant, and is very abundant at the Adyar, Ennore, the mouth of the Godavery, and between Quilon and Anjengo.

(7350) *Hydrophylax maritima*, Linn. Seaside *Hydrophylax*. A straggling herbaceous plant, native of the shore of Coromandel, where it shows its pale lilac blossoms great part of the year. The branches run over the sand, sometimes under the surface, and strike root at the joints. It answers well when the sand is moist.

(7351) *Microrhynchus sarmentosus*. Wight. A widely diffused humble plant, common along the sea beach, with long flagelliform runners; but may not possess sufficient strength to effect the object in view. It is well figured in Wight's Illustrations, Vol. II., t. 133. (Plate No. 5).

(7352) *Pupalia orbiculata*, Wight. *Achyranthes orbiculate*, Heyne, Wallich, *Cyathula orbiculata*, Moquin.

Adai Yotti, TAM.

Occurs on sandy soils near the sea beach, abundant at St. Thome, and near the mouth of the Adyar River. It is an extensively spreading procumbent plant, the branches being often several feet long; bristles attaching themselves to the clothes of passengers, cling to them with tenacity.

(7353) *Pandanus odoratissimus*, Linn. (Kaldera bush.)

Taylic Marm, TAM.

A large spreading ramous shrub, often planted in belts, but takes up much room, forms dense thickets, and harbours venomous reptiles. The lands in which Chay Root is cultivated are often protected from drift sand by means of this shrub. It is a *very strong binder*, but is objectionable from its raising sand-hills.

(7354) *Ehretia arenaria*, Sand Ehretia Griffith, which is found between 12° and 28° N. L. binds together loose sand, in a minor degree. It may be the same as Ehretia (X) cuneata? Wight Icon. Vol. IV. t. 1385 which grows on sand banks in the beds of all our rivers.

The above are the sand-binding plants most frequently noticed along the Coromandel beach. There are others as *Pedalium murex*, *Ipomœa pes tigridis* and *Sesamum prostratum*, &c., which co-operate in the work of conservation to a minor extent, but are less widely diffused along the coast; also Fagrœa Coromandellia. Trees such as the Cashew (*Anacardium occidentale*) the Alexandrian Laurel (*Calophyllum Inophyllum*) and the wild Date (*Phœnix sylvestris*) grow well, and render a double service by preventing a further encroachment of sand, and rendering the land useful.—*Cleghorn.*

(7355) SANDA. A sort of Lizard. It is distilled in Ajmeer and the product applied by Mohammedans, to the penis: the reptile is also eaten as an aphrodisiac.—*Gen. Med. Top. p.* 151.

(7356) SANDAL WOOD. SANTALUM ALBUM. SANDAL WOOD TREE. and its WOOD.

Chandana, HIND BENG.	Kat chundan, HIND.

Sandale, FR.	Chendanum, TEL.
Sundul, Sookur, GUZ. & HIND.	*Faulkner.*

Sandal wood is much used among the Chinese in cabinet work, and in the manufacture of fans and other ornamentnl works. One kind is the produce of a small tree (*Santalum album*) growing in India and Ceylon, which gives its title to the natural order of plants called *Santalaceæ* or Sandalworts. The sandal-wood of the Sandwich islands is from two other species of the same family, *S. Freycinetianum* and *S. paniculatum*. In the native medical practice of India, Sandal-wood furnishes a sedative cooling medicine: it is also largely employed as a perfume in the funeral ceremonies of the Hindoos. By the Chinese it is ground into powder and used as a cosmetic. The bark affords a beautiful red dye, but so fugitive as to be useless. The tree grows freely among the mountains of Malabar, near the sea coast, whence Calcutta obtains her supply of sandal wood, and in Timor and the Feejee islands, from which China derives her chief supply. The tree is cut down when about 9 inches diameter at the root; it is then cleared of its bark, and cut into logs, which are buried for six weeks or two months in order that the white ants may clear off the outer wood; this they do most effectually, without touching the heart of the tree, which is the only valuable part. Sandal-wood should be of a fine deep yellow brown, and highly perfumed. The average importation of this wood into Calcutta is 200 tons per annum. The Chinese imported an amount of sandal-wood in 1838 worth about one hundred and fifty-thousand dollars, but this is said to be doubled in some years. The supply to Europe is very small and chiefly derived from that which has been brought over by individuals without a view to commerce.—*Tomlinson.*

An aromatic wood obtained from a small tree (*Santalum album*); resembling the myrtle, found in Malabar, Timor, and in the Sandwich and Feejee Islands. It is much used in India and China for burning in temples, for cabinet-work, toys, fans, and perfumes. Sandal wood is imported into Bombay from the Malabar Coast, and is re-exported to China, England and Calcutta. A description of white sandal wood, termed (*Vern*) Lava or Lawa, is imported into Bombay from Zanzibar, and is applied to the same purposes as Malabar sandal wood. The wood is extensively employed as a perfume in the funeral ceremonies of the Hindus. The deeper the colour, which is of a yellow-brown, and the nearer the root, the better is the perfume. Malabar produces the finest sandal

wood but it is also found in Ceylon, and the South Sea Islands. It is imported into England in trimmed logs from 3 to 8 and rarely 14 inches diameter, the wood is in general softer than box-wood, and easy to cut. It is used for parts of cabinets, necklaces, ornaments, and fans. The bark of the sandal-wood gives a most beautiful red or light claret coloured dye, but it fades almost immediately when used as a simple infusion, in the hands of the experienced dyer it might, it is supposed, be very useful—*Tredgold.*

Two species of this wood are however known in commerce—the *white* and the *yellow*. Ainslie states, and his opinion is generally received, that both are from the same tree, the former being the outer layers of the wood.

The *white sandal-wood* is coated with thick, compact bark, having a grey and brownish epidermis; the wood is very hard, heavy, susceptible of a fine polish. It occurs in billets of middling size, is nearly inodorous, its taste being slightly bitter.

The *yellow*, or *citron sandal-wood*, is straight or twisted, lighter than water when taken from the trunk, heavier if from the roots in yellow, fawn-coloured, or reddish billets, slightly shining, of middling hardness, taking a fine polish, and being very easily cleft.

The odour of this wood is very strong, rose like, and enduring, its taste slightly bitter. The wood of the *Plumelia alba* is occasionally substituted for the true sandal. The odour is due to the presence of an essential oil, heavier than water, readily congealed, and having a peculiar sweet smell. Sandal-wood is extensively used by cabinet-makers for the fabrication of various articles of ornamental furniture. The oil is employed by the European perfumers, and in India is very extensively used for the adulteration of attar of roses. The wood in powder is given by the native physicians in ardent remitting fevers, and supposed to be sedative and cooling; with milk it is also prescribed in gonorrhœa. (*Ainslie.*) The powder is rubbed on the skin to ally the irritation of musquito bites, of prickly heat, and other cutaneous disorders.—*O'Sh. page* 532. Sandal wood grows in the islands of the Malay Archipelago but more especially in Timor and in the island which takes its European name from it. From these it extends to the South sea islands, having been found in the Fijie, Marquesas and Sandwich group. The Chinese consume it largely as an incense, perfume and fancy wood.—*Crawfurd, p.* 375. It is often elegantly carved. At the Madras Exhibition of 1855, a box exhibited by Mrs. Wilkieson, was undoubtedly the best specimen of the sandal wood carving. The figures and ornaments were taken from the sculptures in the celebrated temple of Hullabede in Mysore, they were boldly and deeply cut and well finished. The work was executed under the direction of Captain Cunningham of the Mysore Commission and was carved by a native of Soorub, from careful drawings prepared expressly for the purpose. Some very creditable specimens of carved sandal wood were exhibited by the Bangalore Local Committee, of these the most deserving of notice are two large and two small boxes carefully finished and varied in the design; but not so bold in relief as the box from Soorub. The Bangalore Local Committee also exhibited two rosewood carved boxes, very similar in design to those made of sandal wood. The ornaments were all floriated without figures and clearly cut, but the general effect of the work was spoilt by the deep ground work being dotted instead of being left flat. The Canara Local Committee contributed a well carved sandal wood chess table, a model of a Hindoo car, and some neatly finished boxes, one of which was inlaid with ivory and metal. Mrs. James Fraser exhibited two card cases and a work box carved at Ganjam, a district where the manufacture has been recently introduced. Well carved sandal wood chowries were exhibited by Lady Montgomery, and the Madras Local Committee. Mr. Meppen contributed sandal wood bracelets and crochet needle holders made near Cuddoor in Mysore, and Mrs. Bourdillon a box containing sandal wood knitting pins and silk winders. The art of carving in sandal wood though creditable to the Natives of India, as evincing care and laborious industry, owes its chief value to the quaintness of the designs and the elaborate nature of the work. As a branch of the fine arts it can hardly be ranked under the head of carving, as many of the specimens are little more than ornamental surface, showing much of the plain rectangle in the leading forms and little originality of invention.

The art in India, is still susceptible of great improvement. Some neatly finished writing books, card cases and inkstands of sandal wood, inlaid with Ivory, Ebony, and Metal, were contributed by Mr. G. Leonard of Chicacole, were interesting specimens of an Indian manufacture, for which there is an increasing demand. Bombay had hitherto been the chief market for this manufacture, but it is now carried on at Chicacole, Hyderabad, and Vizagapatam. Some creditable specimens of inlaid fancy woods were exhibited by the Travancore Local Committee; the best of these were a lady's workstand with silk winders, and a backgammon board. A carved cocoanut cup mounted in silver exhibited, was deserving of notice.—*M. E. J. R.*

(7357) SANDALWOOD OIL. SANTALUM ALBUM.

Chundana yennai, TAM.; Sundal-ka-Teil, HIND.

The oil of sandal wood is highly valued as a perfume by the natives of India; and is employed in the adulteration of otto of roses. It is chiefly made on the Malabar Coast, whence it is brought to Bombay, and re-exported to England,

China, and the Arabian and Persian Gulfs. The exports from Madras, amount annually to about 100 cwt. Sandalwood oil and the large variety of utturs, &c., which form the principal part of native perfumery are included in this class.—*M. E. J. R.*

(7358) SANDARACH.

Sandroos, Arab, Zoos, Arab.

A resinous substance met with in round or elongated tears, of a whitish or pale-citron yellow brilliant, transparent and limpid, brittle under the teeth, burns with a clear flame, and emits a pleasant odour; taste resinous, and slightly balsamic. It is used as an ingredient in varnishes, and incense; when reduced to a powder, it forms the article termed *pounce*. Sandarach is obtained from Morocco.—*Faulkner.*

Sandarach is said by some writers to exude in hot climates from the bark of the common juniper-tree (*Juniperis communis*). Others state it to be produced by another tree of the pine tribe called *Thuja articulata*, but according to Brongniart and Schousboe, it is the tears of *Callitris quadrivalvis*, also a coniferous tree. Dr. Lindley says, "I have seen a plank two feet wide of this sandarach tree, which is called the "arar" tree in Barbary. The wood is considered by the Turks indestructable, and they use it for the ceilings and floors of their mosques." The resin is received in the form of loose granules or tears, whitish yellow, brittle, and having a faint resinous smell, and acrid taste. It is used dissolved in spirits, as a varnish; it is also employed as incense, and as a pounce-powder.—*Tomlinson.*

(7359) SANDORICUM INDICUM.

Theit-to, Burm.

The only species of this genus is an elegant tree of considerable size, which is found in the Molucca and Philippine Islands, as well as in the Southern parts of India. The leaves are alternate and trifoliate; leaflets entire; panicles axillary with the flowers crowded on the short partial peduncles. The fruit is acid, and sufficiently agreeable to be mixed with syrups to make cooling drinka. Its root is bitter and used in medicine in bowel complaints. It is sometimes called False Mangosteen from some resemblance to its fruit and also Indian Sandal-Wood.—*English Cyclopedia, page* 660. This timber tree is large and plentiful, both in the Rangoon and Tunghoo districts. It is one of those trees which are cultivated by the Burmese for their fruit. It is found near all large villages, but it is scarce in the forests. Wood white colored, adapted to every purpose of house-building.—*McClelland.* The Sandoricum indicum tree bears a fruit the size of an orange, occasionally called the wild mangosteen, to which it bears some resemblance. It has a fleshy acid pulp and makes a very good jelly, but has a peculiar odour. The natives of Tenasserim eat the fruit raw, and esteem it excellent.—*Mason.*

(7360) SANDSTONE, an aggregation of sands by a sort of semifusion as in quartz rock, and in common gritstone, adjoining trap dykes or great faults. In many of the white sandstones the grains merely cohere together. In the sandstones of coal tracks the finer particles of carbonate of lime, clay, oxide of iron, &c., are interposed between the grains: in other cases, as in the Hastings sandstones, an infiltration of carbonate of lime has taken place. Some sandstones are in the laminæ, plane, waved, or slightly concentric: these admit of being readily split. The freestones are not distinctly laminated, the grains being so arranged as to present equal resistance in every direction. They work *freely* under the stone saw and the ordinary picks and chisels. They can also be turned into balustrades, pedestals and vases —*Tomlinson.*

(7361) SANSEVIERA is a genus of Liliaceous plants, of which individuals are very abundant on the coast of Guinea and of other parts of Africa; also around Ceylon and other Eastern Islands, all along the Bay of Bengal, and extending thence to Java and to the coast of China. The leaves are succulent, and abound in fibre remarkable for fineness and tenacity. Dr. Roxburgh proposed that the fibres might be called *Bowstring hemp* in England, because the natives of the Circars make their best bowstings of them.—*Royle.* This genus, indeed, is remarkable for the strength and fineness of the fibres of their leaves. The genus is characterised by having a corol-like funnel-shaped perianth, which has a long rather straight tube, a sexifid limb, of which the divisions are either spreading or revolute. Stamens 6, inserted into the throat; filaments filiform; ovary 3-celled; ovules solitary; style filiform; stigmas obtuse, obscurely 3-lobed. Berry 3-celled, 3-seeded, or, from becoming abortive, 1-celled and single-seeded. The plants have a thick creeping root-stock, with radical equitant leaves, which are fleshy and often spotted; the stem-leaves are scale-like, and the flowers in racemes or thyrsi. In Britain they are easily cultivated and propagated in sandy loam in bark stoves. —*Eng. Cyc.*

(7362) SANSEVIERA LANUGINOSA, is a species, found on the sands of Malabar, while *S. Guineensis* is a species found along a great extent of the west coast of Africa, and which, from affording fibres which, like those of the Indian species, are fine and strong, has been called African Bow-String Hemp. This has been proposed as a substitute for and considered even superior to New Zealand flax. *S. Guineensis* is distinguished by having uniform lanceolate leaves, the style twice as long as the stamens; the

bracts only a third of the length of the tube of the corolla ; the flowers sessile.—*Eng. Cyc.*

(7363) SANSEVIERA ROXBURGHIANA, is a species, according to Mr. Haworth, which was confounded with S. Zeylanica, by Dr. Roxburgh, and which the latter has figured in his 'Coromandel Plants.' It has linear ensiform leaves, which are channelled, keeled, subulate at the apex, green, and longer than the scape ; style as long as the stamens ; the bracts minute. Dr. Roxburgh describes this plant, and says it is called Moorva in Sanscrit, and in Bengalee Moorba, that in English it may be called Bow-String Hemp, and that it grows very commonly under bushes in the jungles in almost every soil in the southern parts of India. It flowers from January to May. In a good soil, and where the plants are regularly watered, the leaves become three or four feet long, and contain a number of fine remarkably strong white fibres, which run their whole length. The natives make their best bow-strings of these fibres, which are separated by the leaves being placed upon a flat strong table, when one end is pressed down with the foot, and the rest scraped with a piece of hard wood held in both hands. Forty pounds of leaves thus scraped yield about one pound of clean dry fibres. The fibres may be applied to a great variety of uses. As the plant grows readily from the slips which issue in great abundance from the roots, and as they require little or no care, Dr. Roxburgh recommended their cultivation in sandy soils. It has lately been proposed in Calcutta to try the fibre on a large scale for rope-making.—*Eng. Cyc.*

Sanseviera Zeylanica, is found in Ceylon, and along the coasts of Southern Asia ; has smooth oblong-acute, flat, and linear lanceolate, channelled, glaucous leaves, which are shorter than the scape ; the style as long as the stamens, the bracts equalling the peduncle in length. This, like some of the other species, is remarkable for the tenacity and fineness of the fibres of its leaves.—*Eng. Cyc.* This plant appears to abound in most parts of the Madras Presidency, it has narrow striped leaves and resembles the Agave in some of its characters, but produces finer fibres, which are easily separated from the pulp. At the Madras Exhibition of 1855, they were contributed by the Travancore and Tanjore Local Committees, the Madras School of Arts, Mr. Jaffrey and Mr. Thorpe : several of the contributions from other localities were discolored from steeping, and one or two were dirty grey and brittle. This fibre has long been known as a useful material for cordage and it is soft, silky and pliant when well prepared It is about equal to the Agave fibre in point of strength, but as it is a finer material it might be applied to a better description of manufactures. The plant is easily propagated and yields a good crop under cultivation. It was tried against Russian Hemp, on board the *Thalia* East Indiaman, when commanded by Captain Biden, and was highly approved of : it has also been made into fine cloth. Some good thread, twine, rope and cord made from this fibre in the Madras Justice's jail, and house of correction were exhibited by Dr. Hunter, along with ropes made from the Agave, Musa, Yucca, and Calotropis fibres.—*M. E. J. R.* *Sanseviera zeylanica* is the best-known species of the genus and has been so called as being common on the Ceylon coast. From it, as above, has been distinguished *S. Roxburghiana*, common on the coasts of the Bay of Bengal, but apparently on insufficient grounds. It is figured by Dr. Roxburgh himself under its former name in his 'Coromandel Plants,' ii, tab. 184. *S. lanuginosa* is probably a distinct species, the *katu-kapel* of Rheede ('Hort. Mal,' vol xi, tab. 42), which grows on the sands of the Malabar coast. All are closely allied to each other, and to the African *S. guineensis*. Of this, the fibres have been occasionally introduced into the markets of Europe, and by some thought superior to New Zealand Flax. They have been called African Bowstring Hemp. (Royle's 'Himal. Bot.,' p. 391.) The Indian species of Sanseviera was first described by Sir William Jones, in the 'Asiatic Researches,' vol. iv, p. 271, under its ancient Sanscrit name of *Moorva*, and he says, that—"From the leaves of this plant the ancient Hindoos extracted a very tough elastic thread called Maurvi, of which they made bowstrings ; and which, for that reason, was ordained by Menu to form the sacrificial zone of the military class." Dr. Roxburgh describes the plant as common on the jungly salt soils along the coasts, growing under the bushes, and easily propagated on almost every soil, from the slips which issue in great abundance from the roots, requiring little or no care, and not requiring to be renewed often, if at all, as the plant is perennial. The leaves, when thus cultivated, are from three to four feet long. The fibre, which extends their whole length, is separated from the pulpy part of the leaves. The natives place them on a smooth board ; then press one end of the leaf

down with one of their great toes, and with a thin bit of hard stick held between the two hands, they scrape the leaf from them, and very quickly remove every part of the pulp. This can also be removed by steeping the leaves in water till the pulpy parts rot, &c. Dr. Buchanan found apparently the same plant, but which he calls *Aletris nervosa*, employed for making cordage near Bangalore. Before the leaves are beaten to separate the fibres, they are steeped in water fifteen (others say five) days, in order to rot the useless parts; but with Dr. Roxburgh the fibres became discoloured by this process. Dr. Roxburgh sent drawings of the plant and specimens of the fibre (*v.* 'Obs.,' p. 18) as early as the year 1790 to the Court of Directors, and again in 1800 by Mr. Bebb; after he had cultivated a begah (*i. e.*, third of an acre of ground) with this plant. As full grown leaves of three to three and a half feet long yielded about one pound of the clean fibre for every forty pounds of the fresh leaves, Dr. Roxburgh concluded that this plant might be cultivated with advantage. By another calculation he found that one acre would yield 1613 pounds of clean fibre and at a gathering, two of which may be reckoned on yearly, in a good soil a favorable season, after the plants are of a proper age. He also ascertained that a line four feet long, made of *moorva* fibre, bore a weight of 120 lb, when a cord of the same size, made of Russian hemp, bore only 105. The former, moreover, after 116 days' maceration, bore a weight of 30 lb., when the latter was completely rotten. Dr. Roxburgh further observes: "Should it ever become an object of culture, a less expensive and more expeditious method of clearing the fibres from the pulpy parts of the leaves, than that of the natives above mentioned, must be contrived." This seems to have been since done. For the Rev. J. Garrow, as quoted by Mr. Murray, states that, in the year 1831, during his residence in Cuttack, in the province of Orissa, he first by mere accident discovered that the leaf of the *Aloe angustifolia*. [It is not easy to ascertain what plant is here meant, but it is probably only a variety of Agave, as no species of Aloe is known to be indigenous on that coast] of Linnæus, contained a quantity of long white fibres. Perceiving that this material possessed great strength, clearness, and tenacity, he caused some quantities of the leaf to be beaten out with mallets, and the fibres to be withdrawn and in this way collected about three hundredweight of fine grass, the fibres severally running about three feet long. On taking this to Calcutta, Mr. Tapley, chief officer of the Thalia East Indiaman, then lying off that port, had some of it manufactured into ropes. On a fair trail of a three-stranded rope of this material with a similar one of Russian hemp, in raising two and a half hundred-weight of spelter from the hold, the grass faithfully brought it up on three successive occasions; whereas, in applying the hempen rope, twice out of three times it gave way, and in the third trial lost one strand. Both Mr. Tapley and Capt. Biden, the commander, highly approved of the article, as did many commanders of ships of other nations then frequenting the port of Calcutta. "On the writer's return to Cuttack he laid waste the whole of the aloe plant he could discover, without respect to species; and to save time and labour, passed the leaves through a *pressing mill* similar to that used for expressing the juice from the sugar cane. He then caused them to be laid in heaps under water for some days, till the fleshy portion of the leaf was decomposed, by which means the fibres were more easily collected; they were then hackled and baled. In the course of a short time afterwards he discovered a short species of aloe, growing widely and profusely in all the moist woods of the neighbourhood, which the natives called *Moorgubbee*. On experiment, this plant produced a most beautiful fibre, as soft and as fine as human hair, but possessing, notwithstanding, extraordinary strength and tenacity. He derived a great quantity of flax from this plant, which, when portioned off in hanks, bore a strict resemblance to raw silk; indeed, side by side, the difference could not be distinguished. It was this article that first induced the writer to turn his attention to the manufacture of cloth. He engaged two native 'Tantees,' or weavers, to construct a narrow loom for this purpose. They at first found some difficulty in the undertaking, but in the course of four or five days they produced as fine a piece of cloth as was ever beheld: one portion of it the writer presented to Sir Charles (afterwards Lord) Metcalfe." The fibres of the Sanseviera may, from their fineness, combined with tenacity, be applied to a variety of purposes. Dr. Roxburgh at one time supposed, though as we now know, erroneously, that they were identical with China grass. They are usually about two feet in length, but may easily be obtained longer, if plants are cultivated. The fibres are firm, hair-like, and silky, and resemble those of the pine-apple most closely. The tow is excellent for paper making. The natives of Bengal twist the fibres into a fine thread, upon which they string ornaments to be hung round the neck; those of the coast employ them for making browstrings; and the Rajpoot thread is sometimes made of its fibres. They readily take dyes, as was some years ago shown by Miss Davy, and specimens dyed red, orange, maroon, and green, were sent to the Exhibition of 1851 by Dr. Hunter. Miss Davy, moreover, had some cloth woven with the fibres, after some difficulty, but the fibre was still too wiry, from imperfect preparation. The weaver, moreover, having neglected to separate the coarse from the fine fibres,

gave the cloth an uneven and irregular appearance. But if the necessary care was taken with this, as with all other fibres, there seems no reason to doubt that it might be applied to the fabrication of fine cloths, in the same way as pine apple fibre The fibre has been proposed for the packing of steam-engines, and its tow used to be, and perhaps still is, converted into very good paper at Trichinopoly. As the Moorva fibre is employed by the natives for their bowstrings, there can be no doubt of its possessing sufficient strength for rope-making. In some recent experiments, this fibre, in its untwisted state, bore 280 lb., when Agave fibre broke with 270 lb. Dr. Wight found some string made of the latter, broke with 362 lb., while the Sanseviera broke with 316 lb., so that these two may be considered as nearly equal to each other in strength. Attention was called to the fibre of Moorgavie by Mr. A. Bond, Master-Attendant at Balasore, who sent to the Marine Board of Calcutta some of the fibres prepared from the leaves of plants growing in the jungly salt soils along the coast from Kedgeree southward, informing the Board that he had found the fibre useful on board the Hon. Company's schooner Orissa, as it answered excellently for running gear. On the receipt of the samples, the Board having desired the Master-Attendant at Calcutta to submit them to trial, the latter reported that it was "not equal in strength to the Europe or Manilla hemp, but that it seemed to take hot tar as well as the latter, and would answer generally for the same purposes as those to which the Europe and Manilla cordage is applied." The following were the results obtained:

Europe hemp, made of sewing twine (untarred)	broke at	212 lb.
Harris's patent colonial bolt rope (tarred)...	„	204 „
Manilla hemp (untarred).....	„	188 „
Europe bolt rope (tarred)...	„	168 „
Balasore fibre (untarred), at Calcutta	„	137 „
Ditto, spun by Capt. Bond (thumb line).....	„	135½ „
Europe rope (tarred).....	„	88 „

In a further report, Capt. Bond stated, that forty maunds of the fresh plant produced one maund of fibre. The expenses of the experiment were high as the plant had to be brought to him from some distance (four miles) to the place where it was dressed, and the best methods of separating the fibre had not been followed. The natives being averse to a work which their forefathers had never taken in hand. The plants having been steeped for eight days, were beaten out on a stone or plank, and then taken to another tank of water to be washed, and then dried and combed. All these processes necessarily increased the expenses. Mr. Bond further ascertained that the steeping spoiled the colour of the fibre, at the same time that it diminished its strength. With some fresh specimens of the fibre he also sent two pieces of cloth, which had been woven from threads spun by fishermen, which were irregular in thickness and so, consequently, was also the cloth. From the abundance of this plant in many situations, from the ease which it may be cultivated, and the facility with which the fibre may be separated and cleaned, there is no doubt that it could be produced as cheaply as any of the other fibres; and it has been shown that it is capable of being used for a variety of purposes, as for textile fabrics, and for string and cordage, as well as for paper-making. It is abundantly diffused, especially along the coasts, and its fibre was sent to the Exhibition of 1851, from Assam and Cuttack, as well as from Madras, Coimbatore, and the Malabar coast—*Royle. Fib. Pl.* At the Madras Exhibition of 1855, of the *Marool or Munjee Nar, Sanseviera zeylanica*, Hurry Row exhibited the best specimen. Those from Kurnool in larger quantities were good samples and deserved notice. The Jury observed that the Marool or Sanseviera is a plant that has not long attracted notice but is unquestionably deserving attention. In some parts of India very large quantities are found, growing wild. On the Pulicat Hills it is to be met with in some abundance, and in the Kurnool District it is most plentiful. It is of the same natural order as the aloe (not agave) and capable of cultivation. From its strength and the softness of its fibre, it might be brought more into use, and become a valuable product, possessing as it does the property of resisting the usual effects of damp.—*M. E. J. R.* The root is in a slight degree warm to the taste, and of a not unpleasant odour; is prescribed by the native Practitioners, in the form of electuary, in consumptive cases and coughs of long standing. The juice of the tender shoots of the plant (which is the Katukapel of the Hort. Mal.) they give to young children for the purpose of clearing their throats of viscid phlegm.—*Ains. Mat. Med. p.* 88.

(7365) SANTALACEÆ, a natural order of Plants belonging to the class of Exogens and and sub-class *Incompletæ*. They are trees, shrubs, or herbaceous plants, with round or irregularly-angled branches; alternate or nearly-opposite undivided leaves, sometimes minute, and resembling stipules. The flowers are small, in spikes, racemes, umbels, or solitary. The calyx superior, 4- or 5-cleft. Stamens 4 or 5, opposite the segments of the calyx. Ovary 1-celled, with from 1 to 4 ovules. Fruit 1-seeded, hard, dry, and drupaceous. Albumen fleshy. This order is closely allied to *Loranthaceæ* and *Aris-*

tolochiaceæ. One of its most remarkable characters is that its unilocular ovary contains always more ovules than one, which are pendulous and attached to the apex of a central receptacle. In the form of weeds the genera of *Santalaceæ* are found in Europe and North America; in Australia the East Indies, and the South Sea Islands, they exist as large shrubs or small trees. *Osyris* belongs to this order, although it differs in having dicœcious flowers and a trifid calyx. This is however a different plant from the *Osyris* of Pliny, which possessed in former times a reputation for curing every disease. The modern genus possesses no sensible properties as a medicine, and is principally employed for the manufacture of besoms, for which its long slender branches well fit it. The Ogeehee Lime, which is used on the Mississippi instead of olives, is the fruit of *Nyssa candicans* The *Nyssæ* form trees of great beauty, and their wood is white, soft, compact, and light. The most valuable genus in this order is its type the *Santalum*, of which the species *S. album* forms the true sandal-wood of commerce.—*Eng. Cyc.*

(7366) SANTALUM, a genus of Plants which gives its name to the natural order *Santalaceæ*, to which it belongs. It has hermaphrodite flowers, the perianth united at the base with the ovary, the limb superior, tubelar, and ventricose, quadrifid, deciduous; glands four, compressed, inserted into the throat, alternating with the lobes of the limb. Stamens 4, inserted into the throat opposite to the lobes of the limb; filaments awl-shaped, loaded with a pencil of hairs behind; anthers 2-celled; ovary half inferior, 1-celled; ovules 2 antropous pendulous from the apex of a free central placenta, style filiform, simple; stigma obscurely 2-3-lobed; drupe berried, 1 seeded; margined at the apex. Seed inverse. Embryo straight at the apex of a fleshy albumen. Radicle above.—*Eng. Cyc.*

(7367) SANTALUM. *Species*. WILD SANDAL WOOD. An inferior kind of sandal wood is produced by a tree in the southern part of Mergui province, and forms an article of commerce.—*Mason*.

(7368) SANTALUM ALBUM. SANDAL WOOD. *Santalaceæ*, Roxb. C.

Chunduna or Ghunda-saru, DUK.	Shandanum, TA[illegible] Gandaga mara, C[illegible]

S. album, or the White Sandal-Wood Tree, [illegible] native of the mountainous parts of the coast of Malabar, and also of Timor and the islands of the Indian Archipelago, and it is probable that the same species extends to great distances. It forms a tree of moderate or rather of small size, but much branched, and in general appearance has been often compared to the myrtle, and in inflorescence to the privet. The leaves are opposite, with short petioles, oblong, entire, smooth, glaucous underneath; length from one and a half to three inches. The inflorescence is in axillary and terminal thyrsi. Flowers numerous, small, straw-coloured, when they first expand, but change to a deep ferruginous purple; they are inodorous, as are all the exterior parts of the growing plant even when bruised. The tree when felled is about nine inches or a foot in diameter; it is then barked, cut into billets, and said to be buried in a dry place for about a couple of months. The deeper the colour and the nearer the root, the more fragrant it is. As seen in commerce it is in compact pieces of a white colour and agreeable odour, but with little taste. It is usually described as being the young and outer wood, and that the inner parts, as they become older, become coloured towards the centre, and that this is the source of the yellow, while the white sandal-wood consists of the outer and younger wood of the same tree. This is the general opinion respecting the origin of yellow sandal-wood, but Garcias thought it in his time to be the produce of a different tree. M. Gaudichaud is of the same opinion, and has moreover figured the plant in plate 45 of the botanical parts of the 'Voyage de l'Uranie.' This he saw in the Sandwich Islands, and has named it *S. freycinetianum*; stating it to produce the sandal-wood which is so much valued by the Chinese, which they also obtain from the Feejie and Marquesa Islands, Moluccas, &c. They manufacture various articles with the yellow sandal-wood, which is the most fragrant. They also burn it both in their temples and private houses as an incense, and especially in the form of long slender candles, which are formed by covering the ends of sticks with the sawdust of sandal-wood mixed with rice paste.—*Eng. Cyc.* In the Dekhan, this tree grows both in gardens and the jungles. It bears a small black berry, which if planted grows without any trouble. The wood is generally brought for sale in small logs seldom exceeding eighteen inches in length. —*Riddell.*

This very valuable tree is found in abundance on the Hills which separate the Coimbatore district from Mysore, whence it is brought to Coimbatore for sale.—*Wight.* Also, in abundance in Coorg and Mysore, and sparingly in Canara. It is usually cut into billets, and disposed of by weight. The scent is believed to be much modified by peculiarities of soil and elevation. (*Wight* No. 94, *Travancore* 263, *Mysore* 1, *Coorg* 3. *Masulipatam, Madras, Hort, Garden* 75, *Cleghorn, Mysore.*) *M. E. J. R.* It is chiefly remarkable for its agreeable fragrance, and as a preservative against insects. It is much used in making work boxes, walking sticks, penholders, and other small articles of fine ornament but cannot be procured of a large size.—*M. E. J. R.* Sandal wood is imported into Tenasserim from Hindustan, and

is constantly for sale in the bazars, being a favorite cosmetic with Burmese ladies.—*Mason.*

(7369) SANTALUM ALBUM.

The oil.

Chendana nuna, Tel.; Chundana yennai, Tam.

Specimens of this oil were exhibited by the Salem and Canara Local Committees, the Madras Tariff, and Lieut. Hawkes. The exports amount annually to about 100 cwt.—*M. A. J. R.*

Santalum album Oil of the Seed. Sandal seed Oil. The seeds of the sandal wood tree yield by expression a thick and viscid oil which is burnt by the poorer classes in lamps.—*M. E. J. R.*

(7370) SANTALUM MYRTIFOLIUM is another species, or a strongly marked variety of *S. album*, found by Dr. Roxburgh in the mountains of the Rajamundry Circar, and which was figured by him in plate 2 of his 'Coromandel Plants:' it is distinguished by its opposite lanceolate leaves. The wood is of little value, according to Dr. Roxburgh, but Dr. Wallich says it is 'certe odoratissimum'. About 200 tons are annually imported into Calcutta from the Malabar coast, and about twice as much into Canton from the islands of the Indian Archipelago—*Eng. Cyc.* Dr. O'Shaughnessy says *Santalum myrtifolium* is synonymous with the S. album of Roxburgh's Coromandel plants, a native of the continent of India, Timor, &c. That it is a small tree, with yellow flowers in stalked, trifid, axillary cymes, leaves narrow and oval, and affords the sandal wood of Malabar. He adds that Roxburgh makes the Santalum album and S. myrtifolium two distinct species. His S. album thrives luxriantly in the Calcutta Garden, and is in flower and seed nearly the whole year.—*O'Shaughnessy, page* 532.

(7371) SANVITALIA PROCUMBENS. A pretty compact plant, and from its nature adapted to cover a small patch or bed, in the flower garden, colour yellow, and raised from seed.—*Riddell.*

(7372) SAPAN WOOD. CÆSALPINIA SAPAN.

Puttung, Guz. Hind.	Sapang, Malay.
Patonga, Sans.	Sachaug, Jav.
Bukkum, Hind.	Samya, Mol.
Isiapungum also Vuttunghy, Tam.	Lolan, Amb.
	Sibukas, Tagala.

The product of a thorny tree (*Cæsalpinia sapan*), indigenous to Siam, Pegu, the Philippine Islands, and the South of India. This wood is similar to Brazil wood, but contains less colouring matter, and is extensively used in India by native dyers. Sapan wood is imported into Bombay from Siam, and Singapore; and an inferior description, in small quantities, from the Malabar Coast. The former kinds are occasionally re-exported to London.—*Faulkner.*

Sappan Wood is an article of considerable commerce in the East. It is the bukkum wood of Scinde, and is procured in Mergui, Bengal, the Tenasserim Provinces, Malabar and Ceylon. In 1842 as much as 78,000 cwts. were shipped from Ceylon, but the export from thence has decreased. This island however, ships dyewoods annually to the amount of £2,000. A large quantity is exported from Siam and the Philippine Islands; as much as 200,000 piculs annually from the former, and 23,000 piculs from Manila. 3,524 piculs were shipped from Singapore in 1851, and 4,074 piculs in 1852. The picul is about one cwt. and a quarter. Sappan wood yields a yellowish colour, like that of Brazil wood (*C. brasiliensis*) but it does not afford of dye matter so much in quantity or so good in quality. It forms a large export from Ceylon: the shipments from thence were, in 1842, 77,694 cwt.; in 1843, 1,692; in 1844, 2,592; in 1845, 2,854. In 1837, 23,615 piculs of sappan wood, and 2,266 piculs of roots of ditto were shipped, and in the first six months of 1843, 22,326 piculs were exported from Manila; a large portion of this comes to Europe, but some goes to China, the United States, Singapore, &c. 15,500 picul were shipped from Manila in 1844, 5,250 ditto in 1845; and 1,210 tons in 1850. About 3,000 piculs of sappan wood and the same quantity of other dyestuffs are annually imported into Shanghae. The price of straight sappan wood at Shanghae in July last year, was thirty dollars per picul. In Calcutta, in June 1850, 4,000 piculs of the root of Manila sappan wood sold freely at about 7s. 6d. per factory maund, Siam ditto 6s. 75 tons were imported into Liverpool in 1849: and 120 tons in 1850, from Calcutta. The imports of sappan wood into the United Kingdom, in 1850 amounted to 3,670 tons, worth £8 to £12 the ton, and this continued the price in January 1853. Camwood, red sanders wood, barwood, and other dye woods, are found in great quantities in many parts of Africa. The dyes of Africa are found to resist both acids and light, properties which no other dyes seem to possess in the same degree. About thirty miles east of Bassia Cove, in the republic of Liberia, is the commencement of a region of unknown extent, where scarcely any tree is seen except the camwood. This boundless forest of wealth, as yet untouched, is easily accessible from that settlement; roads can be opened to it with little expense, and the neighbouring kings would probably give their co-operation to a measure so vastly beneficial to themselves. It is impossible to ascertain the exact amount of export of these commodities to Europe and the United States, but it is very great, and employs a large amount of vessels. One Liverpool house imported 600 tons in a single year, worth £9,000.

Dyewoods imported in 1850.	Tons.	Re-exported. Tons.
Logwood,.....	32,930	4,332
Fustic,.....	9,808	1,774
Nicaragua,.....	7,909	112
Barwood,.....	1,896	1,[illegible]
Sappan,.....	3,670	—
Green Ebony, and Cocuswood, ...	1,457	—
Red Sanders,.....	656	—
Camwood,.....	416	—
Brazil and Brazillito.....	309	—
	59,051	7,444

Thus we perceive the annual consumption of heavy dyewoods in Britain in dyeing cotton, linen, woollen and silk goods, &c., exceeds in weight 51,000 tons.—*Simmonds.* Sapan-wood, or Buckum wood, (Casalpinia sapan,) is obtained from a species of the same genus that yields the Brazil-wood. It is a middle sized tree, indigenous to Siam, Pegu, the coast of Coromandel, the Eastern Islands, &c. It is imported in pieces like Brazil-wood, to which, for the purposes of dyeing, it is greatly inferior, it is generally too unsound to be useful for turning.—*Tredgold.* At the Madras Exhibition of 1855, specimens were exhibited in billets and chips from Tanjore, Travancore, Goa and Cuddapah. A red dye is made from an aqueous extract of the chips of this wood, but it is not reported to be a fast colour, and is principally used for common and cheap cloths. It is precipitated dark brown with iron, and red with alum.—*M. E. of* 1855. In the valley of the Tenasserim, between the latitudes of Tavoy city and the mouth of Tavoy river, the hills that border the valley on the eastern side abound in sappan wood, which is used extensively as a red dye. Considerable quantities are exported every year from Mergui, and that province is usually supposed to contain the tree, though it is really within the province of Tavoy; but the facility of water communication from the interior to Mergui, makes that the only port to which the wood is conveyed. It is rather singular that this narrow locality is the only one in the Provinces so far as I am aware, in which the tree is found. The tree has a much wider range, the Karens inform me, on the Meinam side of the mountain in Siam. More than five hundred thousand pounds have been exported from Mergui during some years between 1830 and 1840; but latterly the forests have not been so productive.—*Mason.* Sappan-wood. (Cæsalpinia sapan.) This dyeing material, the wood of a lowly tree, is found in many parts of the Malay and Philippine Archipelogos, but is most abundant in the island of Sumbawa, and in the provinces of Iloilo in Panay and Pangasinan in the great island of Luzon. In 1850, there were exported, chiefly to Europe and America, no less than 11,000 tons of this article from the port of Manilla. The Sappan-wood is the wild produce of the forests, and that it is indigenous wherever it grows there can be little question. It has, like many indigenous products a distinct name in the different languages, the only agreement, and this not perfect, being between the Malay and the Javanese, in the first of which it is called sapang, the origin of the European commercial and scientific names, and in Javanese sachang. In one language of the true Moluccas we have it as samya, and in another as roro, while in Amboynese it is lolan, and in the Tagala of the Philippines sibukas. It seems probable, however that the Cæsalpinias which produce the dyewood of countries which extend from the 9th degree of South to the 19th of North latitude, may be distinct species. The sappan-wood of Luzon is by from 40 to 50 per cent more valuable than that of Siam, that is, yields by so much more of colouring matter. In this respect all the Asiatic Cæsalpinias rank far below those of Brazil.—*Crawfurd, Dictionary, page* 376.

(7373) SAPINDACEÆ, *Soap-Worts*, a natural order of plants belonging to the calycose group of Polypetalous Exogens. It consists of trees or shrubs, rarely herbaceous plants, with erect or climbing stems, with alternate often compound leaves, rarely simple, with or without stipules, and often marked with lines or pellucid dots. Their inflorescence is racemose or paniculate, with small white or rose-coloured rarely yellow flowers, which are seldom barren or hermaphrodite. The calyx consists of 4-5 sepals, slightly cohering at the base. The petals are the same in number as the sepals, one being occasionally abortive. They are in general furnished with a petal-like scale, but are sometimes naked. They have a fleshy glandular disc occasionally occupying the base of the calyx. The stamens are definite, about twice the number of the sepals. The filaments are free or slightly connate, the anthers 2-celled. The ovary 3-celled, rarely 2-4 celled the cells containing 1-2-3 ovules. Style undivided, or more or less deeply 2- or 3-cleft. The seeds have usually an aril, are without albumen, and have a curved or spirally twisted embryo. They are inhabitants of most parts of the tropics, more especially of South America and India. They are not found in Europe or the United States of America. One genus is found in Australia, *Dodonea.*

This order is closely allied to *Aceraceæ*, from which they only differ in their alternate leaves and petals. The number of their stamens 8, with 5 unequal sepals, point out a relation with *Polygalaceæ*. Their climbing habit and tendency to produce tendrils give them a remote relation to *Vitaceæ*. In this order, although the leaves,

anches, and other organs act in a deleterious anner, yet their fruit and seeds are eatable and holesome. The Litchi and the Longan, favoute fruits in China, are produced by the genus *uphoria*. These fruits are sweet, with a sub-acid ıvour, and when dried are sometimes brought to is country. They are considered a great luxury China, and are sent at a great expence from e provinces of Fokien and Quan-Tong, where ey grow, to Peking, for the consumption of e emperor. Several other genera bear fruits ich are very delicious, and are eaten in Japan d Brazil. *Sapindus* is remarkable for bearing pulpy fruit, the outer part of which has been ed, on account of its detergent properties, a soap. Some of the species of this nus also produce eatable fruits. *Paullinia* another genus which has poisonous proper-s residing in the leaves and other parts of the ant, whilst the fruits are eatable. The whole of e order partakes more or less of these prorties.—*Eng. Cyc.* In China, The seeds of a pindus, besides their value in cleansing, are ɔrn as beads "because," says the Budhists, "all mons are afraid of the wood," one native me means preventative of evil. *Williams' iddle Kingdom, p.* 286.

(7374) SAPINDUS (contracted from *Sapo dicus*, or Indian Soap), a genus of Plants beıging to the natural order *Sapindaceæ*, which s been so called in consequence of the berries many of the species being employed for the ne purposes as soap. The genus is tropical, ntaining between 20 and 30 species, which e found in the tropical parts both of the Old d New World. It is characterised by having e calyx 4-5-partite; petals as many as the als, a little longer, naked or hairy, or with a le above the claw; torus or disc occupying the ttom of the calyx; stamens 8 to 10, inserted tween the margin of the disc and ovary; ovary rarely 2-celled; ovule 1, erect at the base of ch cell; style with a 3-, rarely 2- lobed stigma, uit fleshy, 1- 2-, rarely 3-lobed, each lobe, 1-, rarely 3- seeded, with the seeds furnished th an aril. The species consists of trees hav-g leaves without stipules, with the inflores-ce in racemes or terminal panicles. Flow-small, white, or greenish-white. Berries red and saponaceous, on which account they ve been employed for washing woollens and ths of various kinds in different countries. For tance, in the West Indies and the continent of nerica, *S. saponaria* yields the so-called soapрries, and in Java, *S. Rarak*; so in India, veral species, as *S. acuminatus*, *S. laurifolius*, *emarginatus*, and *S. detergens*, yield berries ich are called Reetha, and in their dried state ıy be bought in every bazar, as they are erywhere employed as a substitute for soap. e fleshy part of these berries is viscid, and in ying assumes a shining semi-transparent appearance; when rubbed with water they form a lather like soap. The bark and root have similar properties, and have been employed for the same purposes, as well as medicinally, in the countries where they are indigenous. The berries, which are about the size of cherries, inclose black shining nuts, which used formerly to be much imported into England and employed as buttons for waistcoats, after having been tipped with gold, silver, or other metal. The kernel of these nuts contains an edible oil, which is sometimes employed for burning. The fruit of *S. Senegalensis* and of *S. esculentus* are eaten, and the wood of some species, as of *S. rubiginosus*, is close-grained and hard, and forms valuable timber.—*Eng. Cyc.*

(7375) SAPINDUS EMARGINATUS.

The Tree.

Rete ka jhar, HIND.	Koonkoodoo chettoo, TEL.

Soap nut or koonkoodoo wood, ENG.	Koonkoodoo kurra, TEL.

The Nut.

Soap nut, ENG.	Rishta, DUK.
Koonkuda kaya. TEL.	Bindake. HINDEE.
Rete kee binj. HIND.	Arishta, Phemla, SANS.
Ponnaung cottai. TAM.	Rarak, MALAY.
Ritah, DUK.	

When this substance is mixed with water it froths like soap, and is used instead of that substance for many important purposes, Dr. Sherwood has mentioned that the seeds pounded with water often put an end to the epileptic paroxysm a small quantity being introduced into the patient's mouth. Another species, the *S. Saponaria*, has been used in medicine in the treatment of chlorosis, in the form of the tincture or extract of the soapy matter of the capsule. The nuts themselves are exceedingly hard and tough, and as they take a fine polish are employed for necklaces and beads. The kernels of the small black nuts of the S. Saponaria are eaten in the West Indies, and deemed as palatable as the hazel nut or almond. The roots as well as the capsules are used in washing, but it is stated that the fabric washed is rapidly corroded; this however requires confirmation. (Fee, vol. ii. p. 48.)—*O'Shaughnessy, page* 241. Wight suspects the Poochay Cottay marum, to be the same as Roxb. S. detergens. The fruit is used for the same purposes as indicated by the characterestic native name. His S. emarginatus may be a different plant as the fruit does not correspond. He does not know the wood further than that is white, said to be only fit for fuel.—*Wight.* Under the Canarese name of *Thaly Marathoo*, Mr. McIvor says that the Sapindus emarginatus is a small tree, wood elastic,

strong and durable, common in Wynaad.—*McIvor, M. E. of* 1857.

(7376) SAPINDUS EMARGINATUS.

The oil

Poonga & Soapnut oil, ENG.	Koocoodie noona, TEL.
Poovandie cottay or Poongum-kai yennai, TAM.	Reethay ka tael, HIND.

This semi-solid oil is used medicinally by the natives, and is extracted from the kernel of the Soap-nut. Its cost prevents its general use.—*M. E. J. R.*

(7377) SAPINDUS FRUTICOSUS. Introduced into the Dekhan from the Moluccas, flowers in racemes.—*Riddell.*

(7378) SAPINDUS INDICUS.

Hoorooa, DUK.

A small tree, flowers irregularly, fruit round and hard; three celled with a seed in each and which are used by the natives for intoxicating fish, the taste of the fruit is nauseous and the juice of the tree is considered poisonous.—*Riddell.* See SAPIUM INDICUM.

(7379) SAPINDUS RUBIGINOSUS, Lin Rusty Soap-nut tree.

Rusty soap nut, ENG.	Hseik-kyee, BURM.
Kookoodoo, TEL.	Reetee ka jhar, HIND.
Ishy rashy, TEL.	Manee poongum, TAM

A large timber tree which grows in the mountainous tracts of the Circars. The wood is very useful for a great variety of purposes being straight, strong and durable.—*Ain's. Mat. Med. p.* 213. The Ishki rashy yields a useful timber but so full of sand, particularly near the bark, that it injures tools employed on it.—*Rohde.* The wood of this tree is useful for a great variety of purposes, being large, straight, strong, and durable, towards the centre, it is chocolate colored, its name is derived from the quantity of silex or sand it contains particularly near the bark and which injures tools used in working it: when dry it has something the appearance of Teak.—*Rohde M. S. S.* In Pegu, this tree is not very plentiful. It is found in the Pegu district, where it attains a girth of three or four feet, growing tall in proportion and straight. Wood, white-colored, adapted to every purpose of housebuilding.—*McClelland.*

7380) SAPINDUS SAPONARIA. ARITHA, RITHA, SOAPNUT. The dried berries are brought to Ajmere from Kotah, Malwa, and Mewar, they are not used in medicine; but are much employed in dyeing, and as a detergent: eight seers are sold for the rupee.—*Gen. Med. Top. p.* 122.

(7381) SAPIUM, a genus of Plants belonging to the natural order *Euphorbiaceæ.* The flowers are monœcious, the calyx bifid and 3-toothed, the style trifid, and the capsule 3-coccous.—*Eng. Cyc.* Wight gives Sapium baccatum, 1950-2; Indicum, 1950.

(7382) SAPIUM INDICUM, Roxb. iii. p. 692.

Hoorooa, BENG.

Grows in the Delta of the Ganges. *S. Indicum* has alternate stalked leaves somewhat pendulous, broad, lanceolate, serrate, smooth, and of a deep shining green, from 2 to 4 inches long, and broad in proportion; the stipules small and deciduous; the calyx is 3-parted, the divisions somewhat cordate and expanding; the filaments longer than the calyx, the anthers ovate; the female flowers at the base of the catkins often solitary; the capsule or nut is globular, of the size of a nutmeg, 3 celled, 6-valved, thick, and exceedingly hard; the seed is solitary, affixed by the apex, oval, and smooth. The juice of this species, like the former, is highly poisonous. (Lindley. *Flora Medica*; Burnett, *Outlines of Botany*) —*Eng. Cyc.* Capsule or nut globular, size of a nutmeg, 3 celled, 6-valved, thick and exceedingly hard, seed solitary, fixed by apex, smooth, juice very poisonous, taste exceedingly nauseous, seeds used for intoxicating fish. *Roxb—O'Shaughnessy, page* 562.

(7383) SAPIUM SEBIFERUM. TALLOW TREE. This tree is not very common in the Dekhan, and is only to be met with in a few gardens. It is an ornamental tree, and bears flowers and fruit for the great part of the year together. The fruit is of a pear shape, yellow and red, which when ripe opens and displays two or three black seeds enveloped partially with a fatty-looking substance. It is from this the Chinese extract the tallow and make into candles.—*Riddell.*

(7384) SAPODILLA PLUM. ACHRAS SAPOTA. In Tenasserim, in a few European gardens may be found the tree which produces the Sapodilla plum: whose "fruit, in appearance like an old decayed potato, is yet the most luscious in the West Indies."—*Mason.*

(7385) SAPONACEOUS PLANTS. Many tropical plants furnish useful substitutes for common soap. The aril which surrounds the seed and the roots of *Sapindus Saponaria,* an evergreen tree, is used as soap in South America and the West Indies under the name of soap berries. The seed vessels are very acrid, they lather freely in water and will cleanse more linen than thirty times their weight of soap, but in time they corrode or burn the linen. Humboldt says that proceeding along the river Carenicuar, in the Gulf of Cariaco, he saw the Indian women washing their linen with the fruit of this tree, there called the parapara. Some other species of *Sapindus* and of *Gypsophila* have similar properties. The bruised leaves and roots of *Saponaria officinalis,* a British species, form a lather which much resembles that of soap, and is similarly efficacious in removing grease spots. The bark of many species of

uillaia, as *Q. saponaria*, when beaten between ones, makes a lather which can be used as a ubstitute for soap, in washing woollens and lk clothes, and to clean colors in dyeing, in hili and Brazil, but it turns linen yellow. The uit of *Bromelia Pinguin* is equally useful. A egetable soap was prepared some years ago in amaica from the leaves of the American loe (*Agave Americana*) which was found s detergent as Castile soap for washing nen, and had the superior quality of mix- ng and forming a lather with salt water s well as fresh. Dr. Robinson, the naturalist, thus describes the process he adopted in 767, and for which he was awarded a grant by ie House of Assembly :—"The lower leaves of ie Curaca or Coratoe (*Agave karatu*) were passd between heavy rollers to express the juice, hich, after being strained through a hair cloth, as merely inspissated by the action of the sun, r a slow fire, and cast into balls or casks. The nly precaution necessary was to allow no mixare of any unctuous materials, which destroyed ie efficacy of the soap. A vegetable soap, which as been found excellent for washing silk, &c, ay be thus obtained. To one part of the skin f the Ackee add one and a half part of the *Agave aratu*, macerated in one part of boiling water or twenty-four hours, and with the extract from his decoction mix four per cent. of rosin. In Brazil, soap is made from the ashes of the assura or broom plant (*Sida lanceolata*) hich abounds with alkali. There are also ome Soap barks and pods of native plants sed in China as substitutes for Soap. The ark of Quillaia Saponaria renders water frothy, nd is used as a detergent by wool dyers. aponaria vaccana is common in India. The ericarp of Sapindus emarginatus mixed with ater, froths like soap. Saponaceous berries are ound in Java. The Sapindus is used as a ubstitute for soap, as Sapindus acuminata, lauriolius emarginatus, and detergens, all of them. East Indian plants are similarly used.—*Simonds, p.* 575.

(7386) SAPONARIA (from the Latin 'sapo,' oap,) so called because the bruised leaves are aid to produce a lather like soap when agitated n water), a genus of Plants belonging to the atural order *Caryophyllaceæ*. It has a 5-toothd calyx naked at the base, 5 clawed petals, 10 tamens, and 2 styles ; the capsules are 1-celled, pening at the top with 4 valves ; the seeds are lobular or reniform. The genus SAPONARIA ncludes an article well known in India, the *Saponaria vaccaria*. The properties of this plant re identical in every respect with those of the *officinalis*, or soap wort, the Στρουθιον of Dioscorides. The taste of the entire plant is bitter, the oots are cylindrical, two to three feet long, the hickness of a swan quill, branching above, pidermis ruddy, thick, and easily separable ; parenchyma white and solid. The taste of the root is bitter and mucilaginous ; the infusion is blackened by salts of iron, and the decoction froths like a solution of soap. According to Bucholz' analysis, these properties are due to the presence of a mucilaginous extractive called *saponine*, regarding which an additional notice will be found under the head of *Sapindus emarginatus.—O'Shaughnessy, page* 212. All the species of this genus are very ornamental. *S. ocymoides* is one of the most elegant plants we have in our gardens, and is well adapted for rock-work. (Don, *Dichlamedeous Plants* ; Babington, *Manual of British Botany* ; Burnett, *Outlines of Botany.*)—*Eng. Cyc.*

(7387) SAPONARIA PROCUMBENS. This is a pretty genus of rose coloured, pink or yellow flowers, and from its trailing habit, best suited for covering rock work, cultivated from seed.—*Riddell.*

(7388) SAPOO. A soft, firm, but rather open though even grained, light Ceylon wood.

(7389) SAPOOMIDILE. A soft rather coarse, open grained light Ceylon wood.

(7390) SAPOTACEÆ, OR SAPOTEÆ. Sapotads, a natural order of Plants belonging to the polycarpous group of Monopetalous Exogens. It consists of trees and shrubs, which abound with a milky juice ; the branches are round ; the leaves alternate, simple, entire, coriaceous, destitute of stipules, their under sides being covered by a silky or downy pubescence. The flowers are axillary, regular, and united ; the calyx is 4-8-cleft, imbricate in æstivation ; the corolla is hypogynous, regular, and cleft ; the lobes are equal in number to the sepals and alternate with them ; the stamens are definite and distinct, some are barren and some fertile, the former being alternate with the sepals, the latter opposite ; the ovary is superior, with several cells, in each of which is one erect ovule ; style simple ; stigma undivided ; seeds nut-like, sometimes cohering, unto a several-celled putamen ; embryo large erect, and inclosed in fleshy albumen. This family of plants is most nearly allied to that of *Ebenaceæ*, with which it agrees in habit, its monopetalous regular hypogynous corolla, the absence of a hypogynous disc, its several-celled ovary, and definite ovules and stamens. It differs however in the possession of milky juice, soft wood, hermaphrodite flowers, undivided stigma, and one seeded ovary with erect ovules. The plants of this family are chiefly natives of India, Africa, and America. Some of the species produce fruits which are much prized as articles of diet. Amongst these is the Sapodilla Plum, or Naseberry, which is the produce of *Achras sapota*. The Star-Apple (*Chrysophyllum*); Marmalade (*Achras mammosa*), the Medlar of Surinam, and other eatable fruits, are derived from plants belonging to this order. Most of the species yield large quantities of a milky juice

which, unlike the secretions of most lactescent families of plants, may be used for alimentary purposes. The fruit and seeds abound in oil, which is solid like butter, and has a mild pleasant flavour. The bark of some species of *Achras* is astringent and tonic, and has been recommended as a substitute for quinine. [ACHRAS.]—*Eng. Cyc.*

(7391) SAPOTA ELENGOIDES. A large tree common on the Neilgherries; wood strong and elastic, and like the hawthorn, burns well when green.—*McIvor M. E. J. R.*

(7392) SAPOTEÆ, is a natural order of Trees or shrubs, with simple and alternate leaves, flowers solitary, or in fascicles at the axillæ of the leaves, gorged with a milky white juice. No individual of this order is really dangerous, the juice being devoid of acrid or irritating properties. The barks of many species are astringent, the fruits pulpy, acidulous, and edible. The seeds contain an oil rich in stearine. The butter tree of India, and of Mungo Park. *Bassia butyracea*, is one of this family. It also contains the *Sideroxylon*, or iron wood. The *Achras Sapota*, Sapodilla plum, has delicious fruit with very bitter seeds, believed in Martinique to be powerfully diuretic. The bark is deemed a substitute for cinchona, (Lindley Fl. Med. p 388.)—*O'Shaughnessy, page* 427.

(7393) SAPPHIRE.

Saffiersteen, DUTS.	Safiro, Safir, SP.
Saphir, FR.	Neelum, TAM. and HIND. DUK.
Sapphir, GER.	Sufeer, ARAB.
Zafiro, IT.	Nilam, MALAY.
Sapphirus, LAT.	Neel, CYNG.
Jachant, RUS.	

A beautiful precious stone, and, after the diamond, the most valuable of gems. The colours are blue, red, gray, white, green, and yellow; the most highly prized varieties however, are the crimson and carmine red. Localities, Pegu, France, Germany, and Ceylon.—*Faulkner.* There are several varieties, the names of which are dependant chiefly upon their colour: the *White Sapphire*, which is transparent or translucent; the Oriental Sapphire, which is blue; *Oriental Amethyst* which is purple; the *Oriental Topaz*, yellow; the *Oriental Emerald*, green: and some other varieties occur, as the *Chatoyant* and the *Opalescent Sapphire.—Eng. Cyc. page* 151. Speaking of one of the minerals to which the term Sapphire is applied, Ainslie remarks, this is no other than the Patje Padian or Green Sapphire, in fact the green Sapphire of Werner, and is a stone altogether different from the occidental Emerald, which is known only to exist in South America. The oriental gem is however harder than the American, though inferior in the richness and purity of its green colour. Emeralds are by Mr. Franklin's account found in the dominions of Ava; though Mr. Symes in his Embassy to Ava, tells us that they absolutely never are met with in any part of that country.—*Ainslie.* At another place, he says the best sapphires to be met with in India are brought from the Burman dominions, those found in Ceylon, though genuine, are much less beautiful. On that Island the green Sapphire (Patje Padian) (Cyng) is common —*Ains. Mat. Med. page* 166. According to Tomlinson, *Sapphire* is a gem of a blue colour consisting of pure alumina; it occurs in six-sided prisms often with uneven surfaces. It also occurs granular. When the surface is polished, a star of six rays corresponding with the hexagonal form, is in some specimens seen within the crystal. The sapphire ranks next to the diamond in hardness. When it occurs in *dull dingy-coloured* crystals and masses, the term *corundum* is applied to it, and the granular variety of bluish grey and blackish is called *emery*. [See CORUNDUM; EMERY.] When the sapphire occurs of other *bright* tints, other names are applied to it. The application of the sapphire to the jewelling of watches is well known. Some of the varieties of the sapphire rank next to the diamond in value. Indeed the oriental ruby, of fine colour and free from flaws, is more valuable than a diamond of equal weight. In Mr. Hope's collection is a blue sapphire which cost 8,000*l.*—*Tomlinson.*

(7394) SAPPHIRE, BLUE. Blue sapphires are brought from Burmah, and Dr. Helfer writing from Mergui says: "A Karen informed me, there are precious blue stones to be had, which the Shans collect and carry to Bangkok. He described the place as eight days' distant, and did not know whether it was British or Siamese."—*Mason.* See SCHORL, also TOURMALINE.

(7395) SAPPHIRE, GREEN, or ORIENTAL EMERALD. The green gem is often seen for sale among the Burmese, brought from Burmah, which Europeans usually call emerald; but it is probably a blue sapphire. The true emerald may however be among them.—*Mason.*

(7396) SAPPHIRE, RED, or ORIENTAL RUBY. The red sapphire, or ruby, is brought from Burmah, where it is found with the common blue sapphire, probably in the valley of the Salwen. The Burmese call it by the same name that they do the precious garnet, and do not appear to be always able to distinguish them.—*Mason.*

(7397) SAPPHIRE, VIOLET. The violet sapphire, or Oriental amethyst, is found in the same localities as the common sapphire.—*Mason.*

(7398) SAPPHIRE, YELLOW. The most valuable topaz in Burmah, is the yellow sapphire, or Oriental topaz.—*Mason.*

(7399) SARAPUPPOO NUT. BUCHANANIA LATIFOLIA.

(7400) SARCOCOCCA TRINERVIA; or Neilgherry Box Wood. Tree very common on

the Neilgherries ; wood hard durable, might be used as common Box wood in the Arts.—*McIvor. M. E. J. R.* 1857.

(7401) SARCOCOLLA. Lin. Now of the *Natural order* PENÆALEÆ., Sarcocolla (Unge-root, *Arab,* Runjudéb, *Pers*, Dioscor. lib. iii.)

Unzeeroot, ARAB. | Runjudeb, PERS.

A subacid, sweetish, and somewhat nauseous, gum resin, produced in North Africa, Persia, and Arabia, by a shrub, the *Penaea sarcocolla.* It is met with in small whitish-yellow grains, and is celebrated for agglutinating wounds. It is rarely met with in India.—*Faulkner.* It is yellow, or reddish, like gum arabic, in oblong globules, the size of a pea or of grains of sand, friable, opaque or semitransparent, softening but not melting by heat; sp. gr. 1268. Sarcocolline is half transparent, crystalline, brittle, like gum, soluble in 40 parts of cold water and 25 of boiling water, soluble also in alcohol. Odour weak and peculiar, taste saccharine and slightly bitter; composition, carb. 22, hyd. 19, oxy. 10, atoms. Sarcocolla was once deemed a powerful healer of wounds σαυξ fleshy, and κολλα glue), but this idea has been long abandoned. It is rarely met with in India, and then only brought from Persia and Arabia. Mesure regarded it as cathartic.—*O' Shaughnessy, page* 427.

(7402) SARCOSTEMMA (from σάρξ, flesh, and στέμμα, a crown, in reference to the leaflets of the inner corolla being fleshy), a genus of plants belonging to the natural order *Asclepiadaceæ.* It has a rotate corolla a coronet of double stamens : the outer one cup-shaped or annular crenated, the inner one 5-leaved, higher than the outer one, with fleshy segments ; the stigma is nearly blunt ; the follicles slender and smooth and the seeds comose. The species of the genus are natives of Australia and the East Indies, as well as of South America.—*Eng. Cyc.* Wight gives Sarcostemma brevistigma, ? 595 ; Brunonianum, 1282 ; intermedium, 1281 ; and viminale, 545.

(7403) SARCOSTEMMA GLAUCUM, Glaucous-Leaved Scarostemma, is a lactescent smooth twining herbaceous plant. The leaves are lanceolate, short-stalked slightly revolute, membranous, being with the midrib prominent or the under side, which is glaucous ; the umbels are many-flowerd between the petioles, on very long peduncles ; the segments of the calyx lanceolate, ciliated, and acuminate ; the corolla white, with a large fleshy annular wavy coronet ; the segments of the corolla fringed and spreading. —*Eng. Cyc.*

(7404) SARCOSTEMMA VIMINALE. APOCYNACEÆ.

Soom, DUCK.

A valuable leafless plant, resembling the Euphorbia Tirucalli ; flowers white in the rains, the natives tie the stems up into a bundle and place them in the watercourse of their wells for the purpose of preventing the attack of white ants.—*Riddell.*

(7405) SARCOSTIGMA KLEINII. Poovana Oil was exhibited by the Tinnevelly and Travancore Local Committees, and by the Rev. E. Johnston, Cottayam, and is reported to be useful in Rheumatism. *M. E. J. R.*—The Revd. E. Johnstone of Cottayam forwarded a specimen of the oil of *Sarcostigma Kleinii.* This substance has been long known under the name of Poovana and Poovengah, but this exhibitor was the first to ascertain its correct Botanical name. This medicinal oil is used largely on the Western Coast, and seems especially to merit further investigation.—*M. E. J. R.*

(7406) SARD, SARDONYX.

(7407) SARDINES.

Sardines, FR.	Sardine, IT.
Sasdellen, GER.	Sardinas, SP.

A species of anchovy common in the Mediterranean. They are met with in commerce in a preserved state.—*Faulkner.*

(7408) SARDINE : ENGRAULIS MELETTA ? There is a small fish of the herring family at Tavoy and Mergui, which I have not examined, but Dr. Morton thinks it is identical, or nearly related to the common sardine, a fish of the same genus as the anchovy.—*Mason.*

(7409) SARDONYX. A species of agate, being a variety of onyx, in which the opaque white alternates with a rich deep orange brown, of considerable transparency. The finest are brought from the East. (*Waterston.*)—*Faulkner.* Sardonyx is a variety of onyx which is supposed by some to have received its name from having been brought from Sardes, in Lydia By others it has been said that the name comes from Sardo, the Greek name of Sardinia, there being some reason for thinking that the Carthaginians brought the stones from that island, and exported them during their occupation of it. In this the opaque white alternates with a rich deep orange brown of considerable translucency, and as this is of rare occurrence the sardonyx is of greater value. The finest are brought from the east, and some antique gems are formed of them.—*Eng. Cyc.*

(7410) SARSAPARILLA.

Muckwy, ARAB.	Salsapariglia, IT.
Erramasoomul, Irimusa, CYNG.	Sarza, LAT.
	Shariva, SANS.
Salsepareille, FR.	Zarzaprilla, SP.
Sarsaparille, GER.	Nunnarivayr, TAM.

Sarza, L. E. Sarsaparilla, D. Radix, L. D. Root of Smilax officinalis, *Humb.* and *Bonpl.* L. E., and probably of other species E. of Smilax Sarsaparilla, *Linn.* D. Sarsaparilla.

(7411) *Sarsaparilla,* the roots of several

species of climbing evergreen plants found mostly in warm and tropical climates, and belonging to the genus *Smilax*. The name sarsaparilla is derived from the Spanish word *zarza*, a bramble, and *parilla*, a vine. The original species, *Smilax officinalis*, is a native of South America, but there are several other kinds which also contribute to furnish the roots known in commerce as genuine sarsaparilla, and whose properties are scarcely inferior to it. Of the South American sarsaparilla some reaches us by way of Jamiaca and has the name of that island, while a large quantity is shipped at the Brazils and is called Lisbon sarsaparilla. Varieties of this root are also found in the South of Europe and in India. East Indian Sarsaparilla, long thought to be the root of *Smilax aspera*, but now said to belong to *Hemidesmus Indicus*, is abundant and cheap, and as it appears to partake largely of the qualities of the true sarsaparilla, there is no doubt of its being extensively employed as a substitute. The Smilax China is also largely employed. Sarsaparilla is valued as a restorative to debilitated constitutions. According to Brande there is as yet no good analysis of this root, and the extraordinary medical qualities which it is said to possess are to be attributed rather to its general composition than to any distinct principle.—*Tomlinson.*

The word *Smilax* occurs in Greek authors, and the plant *Smilax aspera*, continues to be employed in medicine. The name Sarsaparilla (from the Spanish *Sarsa*, a bramble, and *Parilla*, a vine) is applied to species of the same genus, and to their roots, first introduced into Europe from the New World in the 16th cenutry. Several kinds, as Jamaica, Honduras, Brazilian, &c., are known in commerce; but it is extremely difficult, if not impossible, at present to determine the species of *Smilax* which yield the several varieties of drug, because much of it is brought over by the Indians from the little known Mosquito coast to Jamaica, and thence imported into England. the greater portion of the remainder is imported from Mexico, Guatimala, Brazil, and Peru.—*Royle.*

(7412) *Smilax officinalis*, *H. B.* and *K.*, was discovered by Humboldt and Bonpland in New Granada on the banks of the Magdalena, in Columbia. As its roots are collected by the natives, called *Zarzaparilla*, and taken to Cartagena, and thence exported to Jamaica, it is more than probable that this yields some of the Sarsaparilla of commerce; hence it is adopted in the L. and the E. P. Dr. Pereira concludes it to be probably the source of Jamaica Sarsaparilla. Martius states that, according to Pohl, the roots are collected in the western parts of the province of Minas Geraes.—*Royle.*

(7413) *Smilax Sarsaparilla*, *Linn.* D., a native of the United States of America; but it does not, according to the evidence of American authors (v. Wood and Bache), yield any of the Sarsaparilla of commerce.

(7414) *Smilax Papyracea*, *Poir.* (S. syphilitica, *Mart.* non Humb.) is a native of Brazil. Martius ascertained that its roots were collected by the Indians on the Rio Negro and other places in the vicinity of the Amazon river, and that they form the *Salsa*, *Salsaparilla*, *Sarza*, or *Zarza*, which is named the Sarsa of Maranhao, of Para, and of Lisbon, and that it abounds more than the other in Parigline. Ejus radices præ cæterarum Smilacum pollent materia illa extractiva, saporis amaricantis, fauces vellicantis, *Parillinum* dicta, cui efficacia medicaminis præcipue debetur."—*Royle.*

(7415) *Smilax Syphilitica. Willd.*, is a distinct species, found by H. and B. on the Rio Cassiquiare, in Brazilian Guiana.—*Royle.*

(7416) *Smilax Medica*, *Schlecht*, was found by Schiede on the eastern slope of the Mexican Andes. The roots are dried and exported from Vera Cruz, but are little known here. Dr. Hancock states that there is but one species that yields genuine Sarsaparilla which manifests to the taste any of the sensible properties of Sarsaparilla; and this grows chiefly on the elevated lands of the Rio Imiquem, at Unturana and Caraburi; also that the Sarsa of the Rio Negro, which comes by way of Angostura or Para, is the best. This is probably yielded by the above *S. papyracea*. Several other species are, however, enumerated by Martius, as *S. Japicanga*, *brasiliensis* and also *Herreria Salsaparilha* as employed for the same purposes, and says "Recentes multo efficaciores, quam exsiccatæ, vetustæ." So *S. Cumanensis* the *Azacoreto* of the natives, *S. Cardato-ovata* of Poppig, *S. Purhampuy*, referred doubtfully to *S. officinalis* by Dr. Lindley, *S. China* yielding the *China-root* of the shops, long famed in the East. It is probable that some of the Indian species are possessed of similar virtues. (*v. Himal. Bot. p.* 383.) —*Royle.* It will have been seen from the foregoing observations that the root of various species of *Smilax* constitutes the sarasparilla of the shops. Sarsaparilla is used in decoction and infusion as a tonic and alterative. The following are enumerated as sources whence sarsaparilla of various kinds is derived.—*Simmonds.*

(7417) *Smilax China* and *sagittæfolia*, yielding the Chinese root, are said to come from the province of Onansi in China.

(7418) *Smilax pseudo China*, *S. Sarsaparilla*, *S. rubens*, and *S. Watsoni*, furnish the drug of North America. The sarsaparilla distinguished in commerce as the Lisbon or Brazilian is the root of *S. papyracea* of Poiret. It is an undershrub, the stem of which is compressed and angular below, and armed with prickles at the angles. The leaves are elliptic, acuminate, and marked with three longitudinal nerves. This species grows principally in

the regions bordering the river Amazon, and on the banks of most of its tributary streams. It is generally brought from the provinces of Para and Maranham. It is in large cylindrical bundles, long and straight, and the flexible stem of the plant is bound round the bundles, so as to entirely cover them. Its fibres are very long cylindrical, wrinkled longitudinally, and furnished with some lateral fibrils. Its color is of a fawn brown, or sometimes of a dark grey, approaching to black. The color internally is nearly white. Besides this species there are others indigenous, such as *S. officinalis*, which grows in the province of Mina ; *S. syphilitica*, which grows in the northern regions, and three new species, *S. sapicanga*, *S Brasiliensis*, and *S. Sarsaparilla* of India.—*Simmonds.* The roots of *Hemidesmus Indicus* were sent to the Madras Exhibition of 1855 from almost every district, but they varied considerably in aroma, the bundle from Trichinopoly being the best. A Syrup and extract from the indigenous plant, growing at the foot of Courtallum hills by 1st Dresser C. Appavoo Pillay, Tinnevelly. Dr. A. J. Scott forwarded a crystallized principle called "Hemidesmine," which was found on examination to be an entirely new substance, exhibiting a remarkable indifference both to acids and alkalies, crystallizing in a peculiar manner in hexagonal plates, which are subject to rapid efflorescence. The only ascertained solvents are alcohol and ether ; it is perfectly insoluble in water, both cold and hot. These facts show that it is a substance of a very peculiar nature. The jury recommended that this preparation be fully tested in hospital practice, along with the extract and syrup prepared from the same plant, and forwarded by 1st Dresser C. Appavoo Pillay. In consideration of Hemidesmine being a new product, the jury awarded a 1st class medal to Dr. Scott, and to C. Appavoo Pillay, Honorable Mention—*M. E. J. R.*

(7419) SARSAPARILLA. Two plants used as such, are common on the slopes of the Neilgherries, the *Hemidesmus Indicus*, and *Ichnocarpus frutescens*, both used as Sarsaparilla.

(7420) SARSAPARILLA. Simple and Compound Decoction of Sarsaparilla, In preparing these decoctions when Sarsaparilla is not obtainable, the China root, (Smilax China,) may be employed.—*Beng Phar, page* 279. An infusion of the Hemidesmus Indicus, (Ununtamul,) is a still better substitute for sarsaparilla. But as much of the virtues of the Ununtamul depend on a volatile principle, it should not be used in decoction, as the long boiling dissipates the active ingredient. For the Mezereon of the London Pharmacopeia, (Daphne mezereon) the dried bark of the Nepal paper plant, Daphne cannabina, may be substituted. The bazar mezereon is almost always inert from age.—*Beng Phar, page* 279. The Assam Sassafras perhaps the bark of Camphora glandulifera is fully equal to the American kind, and may be introduced accordingly, although its source is as yet not perfectly ascertained. Lastly, for liquorice, the goonch, root of Abrus precatorus, may be substituted in this as in many other preparations. —*Phar. p.* 279.

(7421) SARSAPARILLA, SYRUP OF SARSAPARILLA ; SYRUPUS SARZÆ. According to the same formula with which it is prepared may be made syrup of Hemidesmus.—(Ununtamul.) Syrup of China Root,—(Chob China.) These three preparations are alterative and diuretic, and are used to sweeten the decoctions and infusions of the same articles.—*Beng. Phar. page* 409.

(7422) SASSAFRAS. Root of Laurus sassafras, or Sassafras officinale.

Sasafras, ARAB.	Sassafraso, IT.
Cay-Vang-dee, COCH-CHIN.	Sassafras LAT.
Sassafras, FR.	Sassafras, SP.
Sassafras, GER.	

Sassafras, a genus of Plants belonging to the natural order *Lauraceæ*. This is one of the genera into which the old genus *Laurus* of Linnæus has been divided by Nees von Esenbeck and other botanists. It is known by its decœcious flowers, 6-parted membranous calyx, with equal segments permanent at the base. The barren flowers have 9 stamens in 3 rows, the 3 inner with double-stalked glands at the base ; the anthers linear, 4-celled, with their faces turned inwards. The fertile flowers have sterile stamens, which are fewer than, or as many as in, the barren flowers. The fruit is succulent, placed on the thick fleshy apex of the peduncle, and seated on the torn unchanged calyx. The leaves are deciduous. Flowers yellow. The species of this genus most known is the *S. officinale*, the Sassafras Laurel, on account of its medicinal virtues. It is an inhabitant of the woods of North America, from Canada to Florida. It is mostly a small tree or bush, but sometimes attains the height of 40 or 50 feet. Its flowers are arranged in naked downy racemes, which open before the leaves appear, and are furnished with subulate deciduous bracts. The leaves are membranous, bright green, smooth above, finely downy beneath, very variable in form, and tapering in a wedge-like manner into the petiole. The fruit is of a bright blue colour, as large as a small cherry, and seated upon red clavate peduncles. In America, the Sassafras is divided into two varieties, the red and white. Its great use is for medicinal purposes. It is however employed in America for making bedsteads and other articles of furniture, which are not liable to the attacks of insects, and give out a very agreeable odour.—*Eng. Cyc.*

(7423) SASSAFRAS. A species of Sassafras abounds in the Tenasserim jungles, which seems to possess all the properties of the sassafras of America. Mason never met with

the tree in fruit or flower, but the leaf shows that it is not the *Sassafras officinarum.—Mason.*

(7424) SASSAFRAS. LAURUS (SASSAFRAS.?) A species of laurus with the odour of sassafras, is in Tenasserim, often used in house carpentry. —*Mason.*

(7425) SASSAFRAS OF ASSAM, is perhaps the bark of the Camphora glandulifera. It is fully equal to the American kind, and may be introduced accordingly, although its source is as yet not perfectly ascertained.—*Beng. Phar. p.* 279.

(7426) SASSAFRAS PARTHENOXYLON, is a lofty timber-tree growing in the forests of Sumatra The bark is rough and brown. Leaves alternate, rather long, petioled, ovate, acute, often acuminate and varying in breadth, about 3 inches long, entire, with somewhat revolute edges, smooth, glaucous beneath; nerves lateral and irregularly alternate. The fruit has a strong balsamic smell, and yields an oil, considered useful in rheumatic affections. An infusion of the root is used in medicine.—*Eng. Cyc.*

(7427) SASSAFRAS-WOOD, is a species of laurel (sassafras officinalis;) the root is used in medicine. The small wood is of a light brown, the large is darker; both are plain, soft, and close. Sassafras-wood measures from 4 to 12 in. diameter; it is sometimes chosen for cabinet work and turning, on account of its scent.—*Tredgold.* At the Madras Exhibition of 1855, the Jury remarked two specimens of a somewhat rare wood, "Sassafras" both from Mergui. The wood is very fragrant, and contains an essential oil of value in medicine.—*M. E. J. R.*

(7428) SATIN.

Satin, FR.	Raso, IT.
Atlass. GER.	Setim, PORT.

A term applied to a soft, closely woven, twilled, silken fabric, with a glossy surface. Satins are either plain or figured, and are made of all colours.—*Faulkner.*

(7429) SATIN WOOD. SWIETENIA CHLOROXYLON. A cabinet wood, well known for its glossy yellow shades. *Satin wood* is hard in its character, and when polished it is very beautiful and has a satiny lustre, it is much used for picture frames, rivalling the birds eye maple of America. It is occasionally used by cabinet makers for general furniture, but it is liable to split.—*M. E. J. R.* The best variety is the West Indian, imported from St. Domingo, in square logs and planks from 9 to 20 inches wide; the next in quality is the East Indian, shipped from Singapore and Bombay in round logs from 9 to 30 in. diameter; and the most inferior is from New Providence, in sticks from 3½ to 10 in. square; the wood is close, not so hard as box-wood, but somewhat like it in colour or rather more orange; some pieces are very beautifully mottled and curled. It was much in vogue a few years back for internal decoration and furniture, it is now principally used for brushes, and somewhat for turning; the finest kinds are cut into veneers, which are then expensive, the Nassau wood is generally used for brushes. Satin-wood of handsome figure was formerly imported in large quantities from the Island of Dominica. The wood has an agreeable scent, and is sometimes called Yellow Saunders.—*Tred.*

(7430) SATURNIA, a genus of Insects belonging to the order *Lepidoptera* and the family *Bombycidæ*. The antennæ are fringed in the male; the head is small; the wings are very broad and entire; the palpi and trunk are wanting.—*Eng. Cyc.* To the genus *Saturnia* some of the largest of the *Lepidoptera* belong. *S. Atlas*, the Giant Atlas Moth, has wings measuring 7 or 8 inches across. This species also, with *S. Cecropia* and *S. Luna*, have their wings produced into a tail. The cocoons of *S. Cynthia* and *S. Mylitta* are used in India for the production of silk. Latreille states that these are the wild species of silk-worm of China. *S. Cynthia* is the Arrindi Silk-Worm of India. (Roxburgh, 'Linn. Trans.,' vol. vii.) *S. Promethea*, a North American species, forms its cocoon within the leaf of a sassafras-tree, having previously fastened the stalk of the leaf to the stem by a strong silken web, whereby it is prevented from falling with the other leaves. (Westwood.)

(7431) SATURNIA PAVONIA MINOR, the Emperor Moth, is one of the handsomest of the British species of Moths It is about 3 inches wide. The colour is grayish-brown, faintly tinged with purple; the hinder margin of all the wings has a band of pale brown and purple, the hinder band being much waved. The centre of each wing has a large spot or ocellus, which is placed on a light ground; it consists of a black pupil, with a yellow or gray iris, and partially surrounded by a light blue crescent. The larva is of a green colour, having a black band on each segment, adorned with pink tubercles, bearing a whorl of six hairs diverging like a star. It constructs a curious cocoon, the extremity not being close, but terminated by a converging circle of very stiff hairs, which enables the insect to make its escape from within, but completely prevents all ingress.—*Eng. Cyc.*

(0432) SAUCE. Out of eighteen red sauces submitted by Dr. Hassell to examination in 1852, no less than sixteen contained Bole Armenian, and this usually in immense quantites.—*Hassell.*

(7433) SAUSSUREA GOSSYPINA, In East Nepaul at the summit of the Wallan Choon pass, at an elevation of 16,748 feet, above the sea, the plants gathered by Dr. Hooker near the top of the pass were species of *Compositæ*, grass, and *Arenaria*; the most curious was Saussurea Gossypina, which forms great clubs of the softest white wool, six inches to a foot high, its flowers and leaves seeming uniformly clothed

with the warmest fur that nature can devise. Generally speaking, the alpine plants of the Himalaya are quite unprovided with any special protection of this kind; it is the prevalence and conspicuous nature of the exceptions that mislead, and induce the careless observer to generalise hastily from solitary instances; for the prevailing alpine genera of the Himalaya, *Arenarias*, primroses, saxifrages, fumitories, *Ranunculi*, gentians, grasses, sedges, &c. have almost uniformly naked foliage.—*Hooker, Him. Jour. Vol.* 1. *p.* 225.

(7434) SAUNDERS WOOD: RED WOOD: RUBY WOOD: RED SANDERS WOOD. Pterocarpus santalinus.

Undun Sundul-Ahmer ARAB.	Sundul i-surkh BUCKUM, PERS.
Rachta-chandana, BENG.	Rakta-Chandana:
Honnay, CAN.	Ranjana SANS.
Ructchandoon CYNG.	Sigapoo Shandanum, TAM.
Lalchundun, DUK.	Kuchandanum TEL.
Sandel-hout DAN.	RuttunjeeGUZ.HIND
Santale rouge, FR.	Sandalo roso, IT.
Sandal-holz, GER.	
Ruckta-chundun,	

A heavy, insipid, and nearly inodorous wood, the product of a useful timber tree (*Pterocarpus santalinus*), found in Malabar, Mysore, Timor, and Ceylon. The wood is extremely hard, of a fine grain, and a bright garnet red colour, which brightens on exposure to the air It is employed to dye lasting reddish-brown colours; it communicates a deep red to alcohol, but gives no tinge to water—*Faulkner*. Red saunders wood is principally shipped to England from Calcutta in logs from 2 to 10 inches diameter, generally without sap, and sometimes in roots and split pieces, it is very hard and heavy, it is very much used as a red dye wood, and often for turning. The logs are often notched at both ends, or cut with a hole as for a rope, and much worn externally from being dragged along the ground; other woods as also indeed Ivory tusks, are sometimes perforated for the like purpose.—*Tredgold* (Pterocarpus santalinus) a large tree, growing on the Pulicat and Tripaty mountains. The wood is usually seen in billets of 2 to 3 feet in length, of a deep red colour, the concentric circles being divided by dark lines. With different mordants, it yields various shades of red, these are said not to be permanent. This wood is largely exported from but little used in Madras. The Madras exports for 1854 amounted to 47,431 cwts. value 59,570 Rupees.—*M. E. J R.*

(7435) SAVARY KEERAY.

Savary keeray, TAM.

This green, says Ainslie, I have never seen, nor do I believe that the Botanical name of the plant has been ascertained. It grows in the southern parts of the peninsula and is eaten by the common people.—*Ainslies' Mat. Med.* v. 256.

(7436) SAVE, *Canarese.*

Samulu, TEL.

There are two sorts of this grain, viz. Hari Save and Hejjane. Poor people use them in food. It sells in Bangalore? seers for a Rupee.—*M. E. of* 1857.

(7437) SAVORY. Satureja hortensis, and montana. Aromatic herbs, now fallen into disuse, used to flavour soups, &c.

(7438) SAWS.

Scies, FR.	Seghe, IT.
Sagen, GER.	Serras, PORT.
Kurwuttee, GUZ. and HIND.	Pili, RUS.
	Sierras. SP.

Are well-known instruments of various sizes, for cutting wood, iron, and other hard substances. They are manufactured on a large scale at Sheffield.—*Faulkner*.

(7439) SAXICOLA, a genus of Insessorial Dentirostral Birds belonging to the family *Sylviadæ*. Three British species belong to this genus as now constituted, the Stonechat, the Wheatear, and the Whinchat. This genus has the following characters:—Beak straight, slender, the base rather broader than high, surrounded with a few stiff hairs; the superior ridge of the upper mandible prominent, the sides towards the point compressed; the point itself curved and indented. Nostrils basal, lateral, oval, half closed by a membrane. Wings; the first quill-feather about half as long as the second; the second shorter than the third or fourth, which are the longest in the wing. Feet; the tarsus rather long, three toes in front, one behind; the outer toe connected by a membrane to the middle toe; claw of the hind toe short, strong, and curved. (Yarrell.)—*Eng. Cyc.*

(7440) SAXICOLA RUBICOLA, the Stonechat. This is the Traquet Rubicole and Moteux Traquet of the French; Saltabastone, Zompacardi, and Saltinpalo of the Italians; Schwarzkehliger Steincehmatzer of the Germans; Clochdery Cerrig of the Welsh; and Stonechatter, Stonesmith, Stonesmich, Stoneclink, and Moor-Titling of the English. It is found in Russia, Germany, France, Provence, Italy, Smyrna, Japan, the Deccan, the banks of the Ganges, the mountains of Upper Hindustan, Senegal, and South Africa (Cape), England, Ireland, and Scotland.—*English Cyclopedia, page* 687.

(7441) SAXIFRAGA. SAXIFRAGEÆ. These well known plants are mostly native of Britain with white, yellow, or pink flowers, the S. umbrosa, the London pride, is a pretty flower, the species are easily cultivated from seed in any garden soil.—*Riddell.*

(7442) SCABIOSA ELEGANS DIPSACEÆ. These plants with the sent of honey are well adapted for ornamenting the flower garden, they are propagated by seed, and grow readily in any good soil, the seed may be sown in

pots at the close of the rains, and the plants removed when a few inches high.—*Riddell.*

(7443) SCAMMONY. CONVOLVULUS SCAMMONIA.

Sukmoonia, ARAB.	Sakmoonia, GUZ HIND.
Scammonee, FR.	Scammonea, IT.
Skammonien, GER.	Escamonea, SP.

A native of Syria and the Levant, recently discovered by Dr. Burn at Kaira in Guzerat. The proper juice of the plant when dried is called *Scammony*. The Scammony of Aleppo occurs in fragments, voluminous, dry, light, spongy, friable, pulverulent, with dull fracture of blackish grey, but covered with grey powder resulting from the reciprocal friction of the pieces, slightly transparent in small flakes, which become white and rather adherent when rubbed with a wet finger; odour disagreeable, taste weak, acrid, bitter, and repulsive, powder greyish white. The species of scammony is often adulterated with concrete juices of a similar kind, with flour, chalk, sand, and earth. According to the analysis of Bourtron La Grange and Vogel, good scammony consists of resin 60, gum 3, extract 2, and earthy and vegetable impurities 25 per 100. The most abundant harvest of scammony is in Smyrna and Aleppo. There are several modes of collection, which give rise to corresponding commercial varieties. The neck of the root being laid bare is divided transversely, and shells placed around the edges to receive the juice as it exudes. This subsequently thickens in the air. The drug collected in this mode, is called shell scammony. This occurs in small porous masses, sometimes smooth, of reddish or whitish grey colour; of waxy fracture, yellowish and half transparent, in thin layers, of disagreeable taste and smell; on drying it becomes adhesive. Instead of shells the leaves of the chesnut tree are sometimes used, and a flattened scammony of good quality collected. If the roots be cut in successive layers, the scammony is inferior, but still esteemed. It is dried either over a slow fire or before the sun, and then moulded into stamped pastiles, of whitish colour. This variety is very rare in commerce. Lastly, an extract is prepared from the expressed juice of the roots and stalks, this is moulded into round masses, of black, vitreous, and resinous fracture. The Arab name of this drug, Ul Sugmoonia, signifies the *purgative*. Several old preparations called "diagredium" (διακρηδιον.) are mixtures of scammony with sulphur and liquorice, and are now no longer used.—*O'Shaughnessy, page* 500, 501.

(7444) SCARITIDÆ, a family of Coleopterous Insects belonging to the section *Geodephaga*, which section corresponds to the genera *Carabus* and *Cicindela* of Linnæus. The *Scaritidæ* have the prothorax separated from the elytra by a narrow cylindrical neck the mandibles are usually large, and armed with strong teeth on the inner side; the labrum is small; the mentum is furnished with a tooth: the antennæ are usually short, and have the basal joint long; the legs are short; the anterior tibiæ are broad, and strongly notched on the outer side, and fitted for burrowing; and the anterior tarsi in the males are not dilated. The body is usually elongated, and straight at the sides; head, thorax, and elytra, are nearly equal in width. The principal genera contained in this family are *Scarites*, *Pasimachus*, *Camptodontus*, *Acanthoceles*, *Clivina*, and *Dischirius*.

In *Scarites* (Fabricius) the mandibles are strongly toothed on the inner side, the second and third joints of the antennæ are obconic, and the following joints are shorter, compressed, and subquadrate. Dejean separates from *Scarites*, under the generic name *Oxygnathus*, the *S. elongatus* of Wiedemann, which differs in having the mandibles more slender and elongated, and destitute of teeth on the inner side. The only known species is found in the East Indies; it is of a very narrow form.—*Eng. Cyc.*

(7445) SCHIZANTHUS GRAHAMI, SCROPHULARINEÆ. This is a genus of pretty showy annuals, colours of the flowers are crimson, white and variegated, and should be grown, and treated as the Scabius.—*Riddell.*

(7446) SCHIZOPETALON WALKERI. CRUCIFERÆ. This is a singular plant with curiously cut petals, and a strong tapering root, and should be grown and potted like the Eschscholtzia.—*Riddell.*

(7447) SCHLEICHE'RA, a genus of Plants belonging to the natural order *Sapindaceæ*. It has a 5-toothed calyx. Petals absent; the disc occupying the bottom of the calyx. The stamens 6-10, inserted between the margin of the disc and the ovary. The ovary is 3-celled, with one erect ovule in each cell. The stigma 3-cleft. The fruit is an indehiscent drupe, with 1, 2, or rarely 3 cells. The seeds are solitary in each cell, and covered with a pulpy arillus; the embryo much curved. The species are trees; the leaves abruptly pinnate, the leaflets nearly opposite. The flowers are small, disposed in spike-like racemes.—*Eng. Cyc.*

(7448) SCHLEICHERA. *Species*, in Tenasserim, the fruit of this tree resembles the wild ramboutan in every thing except that it is covered with prickles half an inch long. It is rarely seen in market but would be a valuable addition to the dessert. The tree grows among the hills of Tavoy.—*Mason.*

(7449) SCHLEICHERA TRIJUGA. SAPINDACEÆ, Roxb. Fl. Ind. ii. p. 277.

Poovoo or poo marum, TAMUL.	Roatangha, TEL.

Grows in various parts of India. Has abruptly pinnate leaves from 8 to 16 inches long, the leaflets 2-4, opposite, sessile, broad, lanceolate or oblong-entire, rather smooth on both sides;

the lower pairs, the smallest, from 3 to 5 inches long. The petioles are a little downy, the stipules wanting. The racemes are axillary, or below the leaves round the base of the young shoots, solitary, in the male simple, in the hermaphrodite often compound, from 2 to 3 inches long. In the male flowers the calyx is cup-like, and 5-toothed. The corolla wanting, the filaments 6 10, erect, and many times longer than the calyx. The anthers oval and erect; the pistil a mere rudiment. The hermaphrodite flowers on a separate tree. The calyx, corolla, and stamens as in the male flower. The disc a fleshy yellow ring, surrounding the insertions of the filaments. The ovary superior, ovate, 3-celled, with one ascending ovule in each cell. The style short, stigma 3-cleft, recurved, slender, and downy The drupe about the size of a nutmeg, a little pointed, covered with a tender gray dry pericarp. The seeds are oblong, and surrounded with a whitish pulpy aril, which is of a pleasant acid taste, and most grateful during dry weather. It is a native of insular and continental India, where the astringent bark, mixed with oil, is used as a remedy for the itch. (Lindley, *Flora Medica*; Lindley, *Vegetable Kingdom*)—*Eng. Cyc.* The wood is very hard. The pulpy sub acid oil is edible and palatable. (*Lindley.*)—*O'Sh page* 242. Wight says (No. 80) that it furnishes a red, strong, hard wood, generally rather small, used to make pestles, spokes for bandy wheels and such purposes, where much strength in small space is required.—*Wight.*

(7450) SCHMIEDELIA (in honour of Casimer Christopher Schmiedel, once a professor at Erlangen), a genus of Plants belonging to the natural order *Sapindaceæ*. It has a 4-parted unequal calyx, 4 petals, the 5th or superior one wanting. The disc incomplete, with 4 glands opposite the petals, 8 stamens inserted in the receptacle, and connate around the ovary at the base. The fruit is indehiscent, 1, 2, or rarely 3-lobed. The lobes roundish, fleshy, or dry, and 1-seeded. The seeds with or without an arillus. The species are trees or shrubs usually with trifoliate, rarely with simple existipulate leaves and racemose white flowers. The racemes are axillary.—*Eng. Cyc.* Wight gives Schmiedelia Cobbe, 964; Rheedii 964; and villosa, 401.

(7451) SCHMIEDELIA COCHINCHINENSIS has its leaves on long petioles, with serrated leaflets, terminal racemes, pilose small petals. The flower is small and white. It is a native of Cochin China on the banks of rivers. The leaves are used as cataplasms in contusions. (Don, *Dichlamydeous Plants*; Lindley, *Flora Medica*).—*Eng. Cyc.*

(7452) SCHMIEDELIA SERRATA. *Syn.* Ornitrophe serrata. Roxb. Fl. Ind. ii. p. 266. Bengal, Coromandel.

Rakhal phul, HIND. | Tautika, TEL.

Schmiedelia serrata has ternate leaves, the leaflets ovate, pointed, serrate, generally blistered, smooth on the back, and from 2 to 3 inches long. The racemes axillary, single, and erect. The flowers small, white, and polygamous. In the hermaphrodite flower, the calyx 4 leaved, and the petals 4, unilateral. The filaments very woolly near the base. The fruit is small, red, and succulent, and is eaten by the natives of Coromandel. The root is astringent, and is employed by the native practitioners in diarrhœa.—*Eng. Cyc.* The Ripe berries are eaten. Root astringent, and employed to check diarrhœa.—*O'Shaughnessy, p.* 242. Schmiedelia serrata, is only a straggling shrub, with very small timber, *Hort. Garden* 43.—*M. E. J. R.*

(7453) SCHORL. Schorl, or black tourmaline, is found in Madura, in great abundance, also in quartz near the mouth of Tavoy river on the east side, and also at the foot of the eastern mountains, near the head waters of the Dahgyaine, north east of Maulmain. These are the only localities in Tenasserim, where Mr. Mason met with this mineral. In both, the crystals are numerous, and in Tavoy they are large, but not so handsome as seen in foreign specimens.—*Mason.*

(7454) *Green Tourmaline.*—A green gem that cannot be distinguished by the eye from beryl, is brought with the Ceylon diamonds; it is however, green tourmaline; as may be ascertained by a very simple test, for beryl scratches quartz, but tourmaline is scratched by quartz.

(7455) *Ceylon Diamonds.*—White jewels of an inferior quality are often offered for sale in Maulmain under the name of Ceylon diamonds, but they are usually made from green tourmaline. White tourmaline, is a rare mineral, but the green variety being common, the jewelers by exposing it to heat expel its colour and it becomes white.—*Mason.*

(7456) SCHREBERA SWIETENOIDES. WEAVERS BEAM TREE.

Mamalinga maram, also Mogalinga maram, TAM. | Makade Chettoo, TEL.

A large timber tree, a native of vallies of the mountainous parts of the Rajahmundry Circars, Balaghat mountains &c. The wood is of a grey colour, very close grained, heavy and durable. It is reckoned less likely than others found thereabout to warp or bind, and is much used for weavers beams and for many other purposes. Dr. Roxburgh proposes its use for scales to mathematical intruments instead of box.—*Rohde M.S.S.*

(7457) SCILLA, OR SQUILLA, a genus of Plants belonging to the natural order *Liliaceæ*. It has 3 sepals coloured and spreading; petals very like them, and scarcely broader; stamens 6, shorter than the perianth, filaments smooth, somewhat dilated at the base, acuminate, entire ovary 3 parted, glandular, and melliferous at the apex; style smooth, simple; stigma obscurely 3

lobed, papillose ; capsule rounded 3-cornered 3-celled ; seeds numerous in two rows flattened with a membranous testa.—*Eng. Cyc.* Scilla is readily increased like others of the Lily tribe ; a light soil is most suitable.—*Riddell.*

(7458) SCILLA INDICA. Called *Iskeel*, by the native gardeners.—*O'Shaughnessy.* Scilla Indica is found on the sandy shores of various parts of India. It has a round white perennial bulb tunicated, about the size of a large apple ; leaves numerous, radical, sub bifarious, ensiform nearly flat, smooth on both sides from 6 to 18 inches long. When in blossom the plant is perfectly destitute of leaves, scape erect, round smooth, naked, including the raceme from 2 to 3 feet long ; raceme very long erect ; flowers remote ; long, pedicelled, drooping. This species is supposed by Dr. Roxburgh to possess the same qualities as S. maritima (Lindley, Flora Medica.)—*Eng. Cyc. p.* 699. This plant occurs on the sea-shores of the Indian Peninsula ; leaves numerous, radical, sub bifarious, ensiform, nearly flat, smooth on both sides, six to eighteen inches long. When in blossom, the plant is entirely destitute of leaves : the bulbs are round, white, the size of an orange ; inodorous, nearly tasteless, and devoid of any medicinal properties but possibly this may have proceeded from their having been collected from an unfavourable locality, or at the improper season, as few plants are so much influenced by climate and circumstances as the squill, instances being known on the Spanish coast of its being quite inert in one locality, while as active as usual at the distance of but a few miles.—*O'Shaughnessy, page* 663.

(7459) SCINCIDÆ, SCINCOLDIANS, OR LEPIDOSAURS, the names given by Gray, Oppel, Fitzinger, and Messrs. Dumeril and Bibron to a family of Saurians.—*English Cyclopædia, page* 699.

(7460) SCINDAPSUS, Of this genus, Wight gives, Scindapsus decursivus, 779 ; officinalis, 778 ; peepla, 780 ; pertusus, 781.

(7461) SCINDAPSUS OFFICINALIS. *Syn.* POTHOS OFFICINALIS ; Officinal Pothos : This creeper, as I judge, says Mason, is not uncommon on the forest trees, of Tenasserim, but I have never seen the plant in flower. This also enters into the native Materia Medica, but it is not used in European practice, although it has a place in Lindley's Flora Medica.—*Mason.*

(7462) SCITAMINACEÆ, a natural order of plants embracing the *Marantaceæ*, with 1 anther-valve, and the *Zingiberaceæ* with 2 anther-valves. The separation of these orders is now generally recognised. [MARANTACEÆ ; ZINGIBERACEÆ.]—*Eng. Cyc. Scitamineæ*, are abundant on the Khassia hills and extremely beautiful ; Dr. Hooker collected thirty seven kinds.—*Hooker Him. Jour. Vol.* II. *page* 281. The hat of the Lepcha in Sikkim is made of leaves of Scitamineæ, between two thin plates of Bamboo work —*Hooker Vol.* I. *page* 131.

(7463) SCIURIDÆ, a family of Animals belonging to the order *Rodentia* [RODENTIA] and embracing the various forms of Squirrels It has the following characters :—Molar teeth simple, with tuberculous crowns ; five above, four below, on each side ; the lower incisors very much compressed. Toes long, armed with sharp claws, four on the anterior and five on the posterior feet : thumb very short. Tail long and tufted Cheek-pouches in some. In others the skin of the sides extended between the anterior and posterior limbs. The geographic range of the Squirrels is very wide both in the Old and New World. None appear to have been discovered in Australia. The *Sciuridæ* have been divided into two principal groups :

A. Squirrels with free limbs.

Genera,—*Tamias, Sciurus, Macroxus* and *Anisonyx.*

B. Squirrels with their limbs invested in the skin of the sides.

Genera.—*Pteromys* and *Sciuropterus.*

(7464) *Tamias* (Ground Squirrels). The species are found in Europe, Asia, and North America.

Tamias Palmarum is the *Mustela Africana* of Clusius ; *Sciurus Palmarum* of Linnæus ; and Le Palmiste of Buffon.

(7465) *Sciurus* (True Squirrels). A slight depression of the frontal bones, and a very slight posterior projection of the same ; profile of the face very nearly straight ; cranial cavity as long as two thirds of the face. No cheek-pouches. Tail distichous.

The species are found in Europe, Asia, India and Indian Islands, Africa, North America South America, and West Indian Islands.

(7466) SCIURUS BARBEI, *Blyth*, a small striped squirrel of Burmah.

(7467) SCIURUS BERDMOREI, *Blyth*, a small striped squirrel of Burmah.

(7468) SCIURUS BICOLOR, a gigantic squirrell abounds throughout the Burmese countries and Malayan Peninsula and northward to the Assam Hills and those of Sikkim, and Nepal, it is the Sc. Macrouroides of Hodgson It has a pale variety in the Malayan Peninsula

(7469) SCIURUS INSIGNIS, *Hors*, a small striped squirrel of the Malayan Peninsula.

(7470) SCIURUS KERANDRENII, is common in Arracan.

(7471) SCIURUS PHAYREI, *Blyth* : a Burmese squirrel.

(7472) SCIURUS PYGERYTHRUS, a Burmese sqnirrel : a supposed variety of Sc. Lokroides.

(7473) SCIURUS RAFFLESII, Vig and Horsf Sc. Prevostii, Desmarest, is a larger squirrel than

Sc. hippurus. It inhabits the Malayan peninsula. It is black above, deep rufo-ferruginous below and on the feet: a very broad white lateral band from mouth to haunch, extending over the outside of the thigh, and more or less greyish from cheek to shoulder: tail of a somewhat duller black than the back, and a little rufescent at tip.

(7474) SCIURUS REDIMITUS, Vander Boon. Sc. rufogularis Gray, a squirrel of Borneo.

(7475) SCIURUS RUFONIGER, Gray, probably a variety of Sc. redimitus.

(7476) *Sciurus maximus*, the Malabar Squirrel. Upper parts and external surface of the limbs bright chocolate-brown, which colour terminates abruptly, and is joined by the pale yellowish-brown on the under parts, forearms, and internal surface, of the limbs. Front of the fore-legs, neck, throat, face, and head between the ears, lighter in colour: a broad darker patch on the rest of the upper part of the head extends from the forehead to the middle of the nose. Back and shoulders sometimes deepening into black. Ears short, covered with long tufted hairs, and brush-like; from the longer part of each ear a narrow line of deep-brown passes downwards and backwards in an oblique direction. Whiskers scanty, long, and black. Claws incurved and strong, those of the anterior thumbs broad, short, and flattened. Tail distichous, the hairs expanding widely towards the extremity, bright chocolate-brown at the base, black in the middle, and chestnut in the extreme third part. Length about 33 inches, of which the tail measures rather more than one-half. It is a native of the Malabar coast.

Sonnerat appears to have been the first zoologist who observed this richly coloured species, the largest of the true Squirrels. It haunts among palm-trees, and is stated to be very fond of the milky juice of the cocoa-nut, as well as of the solid part of the nut. In captivity, it is tame and familiar; but it tries its teeth upon most substances that come within its power and should be guarded against accordingly.

(7477) *Macroxus*. Frontal bones very much depressed: nasal bones but little elongated; a deep depression between the cranium and the face. Tail round. No cheek-pouches. The species are natives of Sumatra, India, Africa, and South America.

(7478) *Pteromys*. Posterior part of the nasal bones a little convex; the frontal bones strongly depressed in their middle and rising slightly afterwards; the posterior parts of the head do not begin sensibly to curve downwards before the middle of the parietal bones; cerebral cavity small, only half the length of the head. The species are natives of Asia, the Moluccas, the Philippine Islands and Java.

(7479) *Sciuropterus*. Differing from *Pteromys* in having the anterior part of the profile line of the head straight to the middle of the frontal bones, where it takes a curved direction, very much arched, without any intermediate depression. Occiput projecting; frontal bones elongated; and the capacity of the cranium comprising three-fifths of the length of the head. The species are found in Northern Asia and North America.

(7480) *Sciuropterus Sagitta* (*Sciurus Sagitta*, Linn.; *Pteromys Sagitta*, Geoff.). This seems to be the *Sciurus maximus volans*, seu *Felis volans*, of Brisson; Le Taguan ou Grand Ecureuil Volant of Buffon. This squirrel has a small rounded head; cloven upper lip; small blunt ears; two warts at the utmost corner of each eye, with hairs growing out of them; neck short. Four toes on the fore feet; and instead of a thumb, a slender bone, 2½ inches long, lodged under the lateral membrane, serving to stretch it out; thence to the hind legs extends the membrane, which is broad, and a continuation of the skin of the sides and belly; the membrane extends along the fore legs, and stretches out near the joint in a winged form: five toes on the hind feet, and on all the toes sharp compressed bent claws. Tail covered with long hairs disposed horizontally. Colour of the head, body, and tail a bright bay, in some parts inclining to orange; breast and belly of yellowish-white. Length, from nose to tail, 18 inches; tail, 15 inches. (Pennant.) This species inhabits Java and others of the Indian Islands. It leaps from tree to tree as if it flew; and will catch hold of the boughs with its tail. It differs in size; that described by Linnæus was the size of our squirrel, whilst that killed by Sir Edward Michelbourne in one of the Indian islands was greater than a hare. Nieuhoff describes this species under the name of the Flying Cat, and says the back is black. He has given two very good figures of it—one in his frontispiece, the other in the page he describes it in. (Pennant.) In the description of Pennant, above given, there are two points which deserve consideration; that which describes the animal as catching hold of boughs with its tail, and that which states its difference in size. The first is given on the authority of Sir Edward Michelbourne's voyage, in Purchas's 'Pilgrims,' and should be received with caution. The second would lead to the conclusion that more than one species had been included under the name of the animal now under discussion. We accordingly find that Dr. Horsfield, in his valuable 'Zoological Researches in Java,' describes two Flying Squirrels (*Pteromys genibarbis* and *P. lepidus*), both nocturnal in their habits, nearly approaching to *S. Sagitta*. He describes the first as living on fruits; the second as found in the closest Javanese forests, where the height of the trees and the luxuriance of the foliage effectually conceal it. In the work last above referred to, Dr. Horsfield has given a 'General Enumeration of Indian Sciuri,' well worthy of the attention of

the Zoologist. He enumerates 16 species of *Sciuri*, 4 of which were first described by himself. These do not include the Flying Squirrels. —*Eng. Cyc.*

(7481) SCLERIA, A very long sedge, grows by the water in the river Soormah near Silhet and is used for thatching: boat-loads of it are collected for the Calcutta market, for which also were destined many immense rafts of bamboo 100 feet long.—*Hooker Him. Jour. Vol.* II. *page* 327.

(7482) SCOLOPACIDÆ, a family of Birds belonging to the order *Grallatores*. The genus *Scolopax* of Linnæus consisted of the following species: *Guarauna, Madagascariensis arquata, Phæopus, fusca, rusticola, Gallinago, Gallinula, Fedoa, Glottis, Calidris, Totanus, limosa, capensis, Lapponica, Ægocephala, alba,* and *candida*. ('Sys. Nat., ed. xii. According to Cuvier, this genus comprehends the following subgenera:—*Scolopax, Ibis, Numenius, Rhynchæa, Limosa, Calidris* (Cuv., *Tringa*, Temm.), *Arenaria*, (Bechst. *Calidris*, Vig.), *Pelidna, Falcinellus, Machetes, Eurynorhgnchus, Phalaropus, Strepsilas Totanus, Lobipes*, and *Himantopus*. (Regne Animal, ed. 1829.)

Mr. G. R. Gray divides the *Scolopacidæ* into the following subfamilies and genera:—

I. *Numeninæ.—Numenius*, Ray; *Limosa*, Briss.; *Terekia*, Bonap.; *Erolia*, Vieill.; *Ibidorhyncha*, Vig.

II. *Totaninæ.—Totanus*, Ray; *Glottis*, Nils.; *Guinetta*, Briss.; *Actiturus*, Bonap.; *Catoptrophorus*, Bonap.

III. *Recurvirostrinæ.—Recurbirostra*, Linn.; *Cladorhynchus*, Gray; *Himantopus*, Briss.

IV. *Tringinæ.—Hemipalama*, Bonap.; *Heteropoda*, Bonap.; *Tringa*, Linn.; *Machetes*, Cuv,; *Pelidna*, Cuv.; (?) *Cocorli*, Cuv.; *Eurynorhynchus*, Nils.; *Ereunetes*, Ill.; *Calidris*, Ill.

V. *Scolopacinæ.—Macroramphus*, Leach; *Rhynchæa*, Cuv.; *Scolopax*, Linn.; *Rusticola*, Vieill.; *Homoptilura*, Gray; *Telmatias*, Boie; *Gallinago*, Ray.

VI. *Strepsilinæ.—Strepsilas*, Ill.

VII. *Phalaropodinæ.—Steganopus*, Vieill.; *Phalaropus*, Briss.; *Lobipes*, Cuv. We now proceed to illustrate the principal Asiatic genera of this family:—

(7483) *Scolopax.*—Bill long, straight compressed, soft, the point enlarged; the two mandibles furrowed for half their length; point of the upper mandible longer than the lower, the enlarged end forming a blunt hook; arête elevated at the base, projecting. Nostrils lateral, basal, slit longitudinally near the borders of the mandible, and covered by a membrane. Feet moderate, slender, naked space above the knee very small; three toes before entirely divided, the external and middle toe united; a hind toe. Wings moderate, first quill rather shorter than, or of the same length as, the second, which is the longest (Temminck.)

(7484) *Scolopax rusticola*, the Woodcock, i the Becasse of the French; Beccaccia of the Italians; Waldschnepfe of the Germans; Holt Snepp of the Danes, Morkuna of the Swedes; Blom Rokke, Rutte, and Krogquist, of the Norwegians and Cyffylog of the Welsh. It is most probabl the Σκολόπαξ of Aristotle. The male has the upper parts varied with ruddy, yellowish, and ash and marked by great black spots; lower part yellowish-red, with brown zigzags; quills striped with red and black on their external barbs; tail feathers terminated above with gray and below with white; feet livid. Length about 13 inches The female is rather stouter and larger, but he colours are less vivid, and the wing-coverts hav many spots. The distribution of this bird is very wide. The species is found in Western Laplan beyond the article circle, in Finland, Russia, Siberia, rarely in Germany, and more rarely in France. A few have been known to breed in Switzerland. It is very common in Italy and a Maderia, Barbary, Athens, Smyrna, Aleppo Egypt, Cashmere, and Japan, are other localities It feeds on worms, snails or slugs, and (accord ing to Temminck) small beetles; but earthworm appear to be its favourite nourishment. Fo these, it bores with its long and sensitive bil with unerring certainty. The Woodcock breed occasionally, not to say frequently, in grea Britain, in Scotland especially. The nest is placed on the ground in a dry warm spot among herbage, and is loosely fabricated of dead leaves, of the common fern principally, and unlined. The eggs, three or four in number, are pale yellowish-white, blotched, and spotted at the larger end with ash-gray, and two shades of reddish-yellow brown, according to Yarrell; of a dirty yellow sprinkled with small spots of pale brown, according to Temminck. When surprised, the old birds have been known to carry off their young in their bills and claws.—*Eng. Cyc.* They are found on the Neilgherries, and in 1842, one wae shot at Kuladghee. We need hardly add that the bird, served with its trail in, is a delicious dish. The Snipes belong to this section. Those most familiar to the English sportsman and ornithologist are the common Snipe, the Jack Snipe, and the Solitary Snipe: Sabine's Snipe (*S. Sabini*) is of very rare occurrence, and indeed the Solitary Snipe is far from common.

(7485) *Scolopax Gallinago*, Linn, *Gallinago, scolopacinus*, Bonap., the Common Snipe. It is the Beccacino and Pizzarda of the Italians; Becassine, or Becasseau, and Chevre Volant, of the French; Heer Schnepfe and Himels Ziege of the Dutch; Watersnep of the Netherlanders; Myr Snippe of the Icelanders; Horsgjok of the Swedes; Hossegioeg of the Danes; and Ysnittan y Fyniar of the Welsh. The

normal number of tail-feathers is 14, varying to 16 (Brehm's Snipe) and 12 (Delamotte's Snipe). Upper parts variegated very nearly as in the Solitary Snipe; neck and breast striped longitudinally; sides striped transversely with white and blackish; middle of the belly and abdomen spotless, pure white; base of the bill ash-colour; the rest brown; feet pale-greenish; length about 10½ inches, of which the bill measures about 2¾ inches. The colours of the plumage, after the spring moult, are brighter and more brilliant with bronze reflections than after the autumnal moult: in winter the hue becomes more ashy.

Varieties.—Pure white; reddish-white; the feathers sprinkled or blotched with white, or some part of the plumage white.

Mr. Gould ('Birds of Europe') states that, although the contrary has been long stated by naturalists, he conceives that the natural range of the Common Snipe is comparatively limited; and that the Snipes from India, Africa, and North America, which have been regarded as identical with our bird, will be found, on examination, to be specifically distinct.

The following localities have been given as the range of the Common Snipe in Europe and Asia:—Russia and Siberia, from Scona to Lapland, Norway, Sweden, Denmark, Faroe Islands, Iceland and Greenland, Germany, Holland, British Islands, France, Spain, Provence, Switzerland, Italy, Hungary, and Illyria.

Marshes, moist meadows, and, in frosty weather, the edges of rushy rills, are the haunts of the snipe. In such situations they have been seen pushing their bills by means of repeated thrusts, quite up to the base in the mud, drawing them back with great quickness, and shifting their ground every now and then. Their food consists of such worms, insects, and small molluscs as haunt such miry places, and they have been shot in the act of feeding on leeches.

Few birds are better eating than a fresh Snipe. The old quatrain says:—

"Le becasseau est de fort bon manger,
Duquel la chair resueille l'appetit.
Il est oyseau passager et petit.
Et par son goust fait des vins been juger.,

Snypes were among the birds admitted to the Earl of Northumberland's table ('Household,' 1512), and were then charged at threepence a dozen.

(7486) *Scolopax major* (*Gallinago major*, Bonap.), the Solitary, Double, or Great Snipe, is the Grand or Double Becassine of the French; Beccacino Maggiore, Pizzordone, and Croccolone, of the Italians, Mittelschnepfe and Doppelschnepfe of the Germans; Poelsnep of the Netherlanders; Great Snipe, Double Snipe, and Solitary Snipe, of the English; and Ysnid of the Welsh. The tail is composed of 16 feathers; midrib of the first quill whitish: the black of the top of the head divided by a band of yellowish-white; eyebrows of that colour; upper parts variegated with black and bright rusty, the last-named colour disposed longitudinally; lower parts whitish-rusty; belly and sides striped with black bands; bill inclining to reddish, brown at the point; feet greenish ash.—(*Temm.*)

(7487) *Numenius*. Bill long, slender, curved, compressed, hard at the point, and subobtuse; upper mandible exceeding the lower, rounded towards the end, canaliculated for three-fourths of its length; nostrils lateral, linear, pierced in the canaliculation; face feathered, space between the eye and the bill covered with feathers. Feet slender, naked above the knee; three toes before and one behind, which last is articulated on the tarsus and touches the ground, the anterior toes united up to the first joint by a membrane. Wings moderate; first quill longest.

(7488) *Numenius arquatus*, the Curlew. It is the Courlis of the French; Ciarlotto Spadone, and Chiurle Maggiore of the Italians; Heel-Spove of the Danes; Der Groose Krumschnoblichte Schnepfe and Kelihacke of the Germans; and Gylfinhr of the Welsh. It is equally diffused from the sultry portion of the torrid zone to the frozen countries of the north: the islands of the Pacific Ocean, particularly Australia, are not devoid of its presence, and we also possess examples from China, Nepaul, &c. (Gould, 'Birds of Europe.') Dr. Andrew Smith brought individuals from South Africa.

(7489) *Numenius phæopus*, Auct., *Scolopax phæopus*, Linn.; genus *Phæopus*, Cuv. This is Le PetitCourlis, or Courlieu, of the French; Chiurlo Piccolo, Chiurlo Minore, and Mengotto, of the Italians; Regen Brachvogel, Kleine Art Brachvogel, Regen vogel and Kleiner Gossier, of the Germans; De Kleine of Regenwulp, of the Netherlanders; Mellum-Spove of the Danes; Smaae Spue of the Norwegians; Whimbrel, Curlew-Knot, Curlew Jack, Jack-Curlew, Half-Curlew, Titterel, Chikerel, and Tang-Whaup of the English; and Goeg Ylfinhir of the Welsh. All the plumage bright ash-colour; longitudinal brown spots on the neck and breast; on the middle of the head a longitudinal band of yellowish-white, with another twice as wide and brown on each side; belly and abdomen white; feathers of the back and scapulars very deep-brown in the middle, and bordered with brighter brown; tail ashy-brown, streaked with brown bands disposed obliquely; bill blackish, but reddish at its base; iris brown; feet lead colour. Length of male 16 inches, bill 3 inches; of female 18 inches, bill 3½ inches.

It is very widely distributed. Denmark, Sweden, Norway, Lapland, Faroe Islands, Iceland, Germany, Holland, France (but more common in Holland than in France or Germany), Italy, Spain, Provence, Madeira, and the central part of North Africa. Asia—Caucasus, Himalaya Mountains, Bengal, and Japan.

(7490) *Limosa.*—Bill very long, more or less curved upwards, soft and flexible throughout its length, depressed, and flattened towards the point; the two mandibles furrowed throughout their length, the point flat, dilated, and obtuse.

(7491) *Limosa melanura*, the Godwit. Bill straight; tail uniform black, with a base of pure white; claw of the middle toe long and dentilated; a white beauty-spot (miroir) on the wings.

Mr. Gould says that this bird inhabits the whole of the European continent, and that examples are found in most collections from Africa and India. With us they are most frequently seen in spring and autumn. They breed mostly in high northern latitudes, but occasionally in England. In Ireland the species is but seldom seen. The food consists of insects and their larvæ, worms, &c. The nest is formed of dry grass and herbage, and the four eggs are light olive-brown, blotched and spotted with darker brown.

(7492) *Tantalus*, Linnæus.—This genus stands between the genera *Ardea* and *Scolopax*, in the twelfth edition of the 'Systema Nature.'

Cuvier places the genus *Tantalus* between the Open-Beaks (*Hians*, Lacep.' *Anastomus*, Ill.) and the Spoonbills (*Platalea*, Linn.). He characterises the genus as having the feet, the nostrils, and the bill of a stork: but the back of the bill is, he observes, rounded, and its point curved downwards and slightly notched on each side; a portion of the head, and sometimes of the neck is, he adds, denuded of feathers. He notices the following species:—The American Tantalus, *T. loculator*, Linn.; the African Tantalus, *T. Ibis* Linn.; and the Ceylonese Ibis, *T. leucocephalus*, the largest of all.

(7493) *Tantalus religiosa*, the sacred Ibis. Abou-Hannes, Bruce; *Tantalus Æthiopicus* of Latham; L'Ibis Sacre, Cuv.

"This," says Cuvier, "is the most celebrated species; it was reared in the temples of ancient Egypt with veneration, which approached to worship; and it was embalmed after its death, as some said, because it devoured the serpents which would otherwise have become dangerous to the country; according to others, because there was a resemblance between its plumage and some of the phases of the moon; finally, according to some, because its advent announced the rising of the Nile. For a long time it was thought that this Ibis of the Egyptians was the *Tantalus* of Africa: we now know that it belongs to the genus of which we are treating. It is as large as a hen, with white plumage, except the end of the wing-feathers, which is black; the last coverts have their barbs elongated, loose, black, with violet reflections, and thus covering the end of the wings and tail. The bill and the feet are black, as well as all the naked part of the head and neck: this part is covered in youth, at least on its upper surface, with small blackish feathers. The species is found throughout the extent of Africa." [Abou-Hannes.]

The other species noticed by Cuvier are—L'Ibis Rouge (*Scolopax ruber*, Linn.; *Tantalus ruber*, Gm.) and L'Ibis Vert, vulg. Courlis Vert (*Sclolopax falcinellus*, Linn). ('Regne Animal.') —*Eng. Cyc.*

(7494) SCOLOPENDRIUM: Filices; Ferns. Mr. Royle informs us that many of these are still used in medicine in India. The rhizomes, or dried leaves of *Scolopendrium*, are sold under the altered name, *Iskoolikundrioon. Those* of Polypodium are called *bulookunboon.* The Asplenium radiatum, *mohrpunkhee*, or peacock's fan, is employed by the natives probably as an anthelmintic.—*O'Shaughnessy.*

(7495) SCOMBRIDÆ, a family of Fishes of the section *Acanthopterygii*, of which the Common Mackerel may be regarded as a type: the Tunny, Sword-Fish, Dory, and Boar-Fish, also belong to this group, which contains a multitude of species and many genera. The body is generally covered with small scales; the tail is usually very powerful and deeply cleft: in most of the species the pectoral fins are long, narrow, and pointed; the dorsal fins are two in number, the foremost of them being composed of bony rays; the hinder dorsal is chiefly supported by soft rays, and is often divided into numerous small false fins. They are provided with numerous cæca, and these are often united in clusters.

(2496) *Xiphias* has the upper jaw elongated, forming a sword.

(7497) *Xiphias gladius*, Linnæus, the Sword-Fish, is an inhabitant of the Mediterranean and Atlantic, occasionally visiting the British coast. It measures from 10 to 15 feet in length. Its body is lengthy and covered with minute scales, the sword forming three-tenths of its length. On its back it bears a single long elevated dorsal fin; there are no central fins. The tail is keeled. The lower jaw is sharp; the mouth without teeth. The upper part of the fish is bluish-black merging into silver below. The Sword-Fish is said to attack the whale, wounding it with its beak. There are many well-authenticated instances of the planks of ships being perforated by the upper jaw of this powerful creature, which, it has been supposed, occasionally attacks the hulls of ships in mistake for the whale. Specimens of ships' timber penetrated by its sword are preserved in many museums. The *Xiphias* is mentioned by Aristotle ('Hist Anim,' viii. 19), who notices the fact of its striking vessels. The young fish is said to be good eating. When very young the body is covered with small tubercles, which disappear before it attains the length of three feet. —*Eng. Cyc.*

(7498) SCOPOLIA ACULEATA, Smith.

Molakarunnay, Tam.

This is a small white root, about the third par

of an inch in diameter, the bark of which is bitter and subaromatic and is considered as stomachic and tonic. It is given in a weak infusion to the quantity of half a tea cup full in the course of the day.—*Ains. Mat. Med. p.* 89.

(7499) SCORPIONIDÆ, a family of the class *Arachnida* order *Pulmonaria*, and section *Pedipalpi*. The animals of this family, commonly called Scorpions, are distinguished from other groups of spiders by their having the abdomen articulated and terminated by a curved spur at the extremity; the palpi are very large, and the terminal segment assumes the form of the lobster's claw, being in like manner provided with pincers; the stigmata are eight in number, and situated along the inferior and lateral part of the abdomen; on the under side of the thorax are two comb-like appendages. The number of the eyes varies from eight to twelve in different species, and some sub-genera have been established upon this character. Those to which the term *Scorpio* is used in its most restricted sense have only six eyes; those Scorpions which have eight eyes constitute the subgenus *Bathus;* and those which have twelve eyes, *Androctonus*. "These Arachnides," says Latreille, "inhabit the hot countries of both hemispheres, live on the ground, conceal themselves under stones and other bodies, most commonly in ruins, dark and cool places, and even in houses. They run with considerable swiftness, curving the tail over the back—this they can turn in every direction, and use for the purposes of attack and defence. With their forceps they seize various insects, on which they feed after having pierced them with their sting. They are particularly fond of the eggs of spiders and insects. The wound occasioned by the species found in the southern parts of Europe (*Scorpio Europæus*), is not usually dangerous; but according to the experiments of Dr. Maccary, made upon himself, the sting of some other and larger species produces serious and alarming symptoms, and the older the animal the more active seems to be the poison. The remedies employed are the volatile alkali, and chloroform used externally and internally, and externally ipecacuan in form of a paste. The young Scorpions are produced at various intervals, and are carried by the parent for several days upon her back, during which time she never leaves her retreat. The pain suffered from the scorpion's sting seems to depend more upon the temperament of the sufferer than any other cause; some suffering much agony, occasionally terminating in death, while others become only slightly agitated.—*Eng. Cyc.*

(7500) SCORZONERA AND SALSAFY. This is a long milky-juiced root. Grows without any difficulty after the rains. It is an annual from the South of Europe. It should be sown either in beds, broad-cast, or planted out in rows at a distance of a foot apart. The root when boiled and dressed is rather a delicate vegetable. It comes to perfection in three or four months. Salsafy—is the black Scorzonera, and requires the same treatment.—*Jaffrey.*

(7501) SCREW PINE OR VACOA. PANDANUS ODORATISSIMUS.

Keora or Kaldera bush.	Seethay Nar and Umbrella Tree.
Thaium, Thaulay Mazalie.	

It grows along the Coasts of the Peninsula of India, and its leaves are extensively manufactured into mats, baskets and hats, at Pulicat, and other localities. The fibre of the leaf is white, soft, glossy, but possessed of little strength, and though but ill suited for cordage, it has been found well adapted for the preparation of a good quality of paper, also for mats, and sacks. It appears to be the same as the P. Sativus of Du Petit Thouars, and the P. Vacoa of Mr. Henley which is described as growing to the height of 30 feet and good sacking is made from its leaves. Its fibrous aerial roots are much employed as paint-brushes. The leaves are cut every second year, beginning when the plant is two years old. Immediately on its removal from the trees, they must be split into fillets, three to four feet long from three fourths to one inch broad at the base, tapering into a point. The Pandanaceæ or Screw-pines abound in the Mauritius or Bourbon but are found also in India, the Straits and Burmah. —*Royle &c.* The number of names by which plants are known in different districts of India is very confusing. The screw pine is a good instance of this. At the Madras Exhibition of 1855, the only clean specimens of this fibre were exhibited by Mr. Underwood, and the Madras School of Industrial Arts. All the others were discolored by rotting. The leaves of the plant are used by the natives for making mats—baskets and hats. There are extensive manufactories of these articles at Pulicat, Cuddalore and several other localities. The fibre of the leaf is white, soft, and pulpy, but possessed of little strength. It appears to be a good material for the preparation of paper, but ill suited for cordage. The aerial roots are much used as coarse brushes for white washing houses, when beaten with a mallet, they open out like a soft brush.—*M. E. J. R.*

(7502) SCROPHULARIACEÆ, *Figworts*, a natural order of Plants belonging to the dicarpous group of Monopetalous Exogens.

The *Scrophulariaceæ* are very widely diffused over the surface of the earth, being found in the whole range of climate between the poles and tropics. Achimenes Cochin-chinensis when pickled, is much esteemed, in the country where it grows, as an article of diet.—*Eng. Cyc.*

(7503) SCYLLARIDÆ, OR SCYLLARIANS, a tribe of Macrurous Decapods, established by M. Milne-Edwards on the genus *Scyllarus* of Fabricius, and forming one of the most remark-

able groups, distinguished at the first glance by the singular conformation of the external antennæ. The antennæ are inserted on the same line below the eyes; the first pair slender, and present nothing remarkable; their first joint is nearly cylindrical and much stouter than the two following ones; finally, they terminate by two very short multi-articulate filaments. The external antennæ are foliaceous and extremely wide; the piece which carries the auditory tubercle is confounded with the epistome, and followed by four joints, the second and fourth of which are lamellar and extremely large. The buccal frame is small, and the jaw-feet are moderate and nearly pediform. M. Milne Edwards divides the tribe iuto three genera *Siyllarus*, *Thenus*, and *Ibacus*.

(7504) *Thenus* (*Scyllarus*, Fabr.; *Thenus* (*?*), Leach). Body very much depressed, and much narrowed from before backwards. Ocular peduncles very long. Eyes going beyond the carapace laterally; the orbits, directed outwards, occupy the external angle. Sternum much wider than in *Scyllarus*. Abdomen with nearly the same proportional length as in those crustaceans.

(7505) *Thenus orientalis*. Length about eight inches.—*Eng. Cyc.*

(7506) SCYPHANTHUS. LOASACEÆ.—These are pretty little yellow flowers, and require the same treatment as the Loasa.—*Riddell.*

(7507) SCUTELLARIA. LABIATÆ.—These plants are handsome when in flower, and are adapted for the front of borders, the colours are purple, yellow, red or blue, the flowers resembling the Antirrhinum, and may be grown from seed in any good garden soil.—*Riddell.* Wight gives Scutellaria rivularis, 1450, and violacea, 1449.

(7508) SEA COCOANUT OF SEYCHELLES: LODOICEA.

Zee-Calappers, CYNG.	Kuddil Tayngai, TAM.
Cocotier de Maldives, FR.	Samatrapoo tainkaya, TEL.
Durya-ka-Nareel, DUK.	Ubdie Narikaylum, SANS.
Guz. HIND.	

This species of cocoanut is convex on one side, and almost flat on the other, oblong, and somewhat pointed at both ends. The shell is dark coloured, and contains a kernel, not unlike that of the ordinary cocoanut, but drier, harder, and more insipid. They are often seen floating in the sea off the coasts of Arabia and Africa, whence they are brought to Bombay; and also from the Laccadive and Maldive Islands. The shells are made into drinking cups, which are used by the Indian devotees. The kernel is used medicinally by native practitioners, in cases of typhus fever, &c.—*Faulkner.* See COCOANUT, DOUBLE; also LODOICEA.

(7509) SEA-COCOANUT OF TENASSERIM: XYLOCARPUS GRANATUM. This is not the famous *Cocos des mer* of the Seychelles, so long the wonder of the world; but a tree very common in the mangrove swamps; and growing near the shore, its fruit falls into the water and floats out upon the sea, which gives rise to its name. The fruit is not edible, but is exceedingly astringent, and regarded by the natives as a specific in cholera.—*Mason.*

(7510) SEAFORTHIA, a genus of plants belonging to the natural order *Palmaceæ*, indigenous to the eastern coast of tropical Australia, and found also in the nearest Asiatic islands, named by Mr. Brown in honour of Francis, lord Seaforth, a patron of botany. The species are elegant in appearance, with pinnate fronds, the genus is described by Labillardiere under the name of *Ptychosparma.*—*Eng. Cyc.*

(7511) SEAHORSE TEETH, are imported into China, chiefly through Macao; they are brought from California and other parts of western America, and are used by the Chinese in the same manner as ivory; they are the teeth and tusks of the walrus, and other cetaceous animals.—*Morrison.* See IVORY.

(7512) SEA KALE. CRAMBE MARITIMA. Cultivation at Madras unknown and it is a vegetable not worth experimenting upon.—*Jaffrey.*

(7513) SEA SHELLS, *insects*, &c. The shores of the islands of the Indian ocean afford a great variety of beautiful and rare shells, the ducal mantle, &c. They are brought hither in junks from the Archipelago, and from the islands along the coast. The assortment of shells for sale here is not so great as might be inferred from the quantities exposed, but by a little search and selection, one can collect many tons, mostly salt water shells. Few or no fresh water shells are collected. Both sorts are sometimes injured by scraping and varnishing them.—Beside shells, as objects of natural history, insects are also procurable at Canton, tolerably well preserved: they are mostly coleopterous insects, as beetles; butterflies and other classes are also gathered, especially those which are gay. Precious stones are seen in small quantities, but rather inferior; chrysolite, malachite, cornelians, agates and jade, are the most common: other minerals, especially limestone and quartz, are cut into fantastic shapes; but these specimens being always lackered, are spoiled for natural objects. [illegible]ds or fishes are seldom seen preserved.—*Mo*[illegible]

(7514) SEAL. The na[illegible] family of amphibious animals, valued for [illegible] obtained from the fat or blubber, and also [illegible] its skin, which is used for a variety of purposes.—*Faulkner.*

(7515) SEALING WAX.

Cire d Espagne, FIR.	Cera Lacca, Cera di Spagna, IT.
Cire a Cacheter, GER.	Surgutsch, RUS.
Seigellack, GUZ.	Lacre. SP.
Chap-ka-Momom, HIND.	

Is a composition of gum lac, melted and incorporated with resin, and afterwards coloured

with some such pigment as vermilion, ixory-black &c. It is used for sealing letters, legal instruments, &c.—*Faulkner. Sealing-wax* is also made from lac, and several varieties have been sent from different parts of India. Garcias ab Orto described it as made from lac in the year 1563. Tavernier mentions the same fact. The Spaniards have obtained credit for the invention; but they, no doubt, learned it from the Arabs. A Frenchman who travelled much in Persia and different parts of the East Indies is also thought to have been the discoverer; and by Beckmann it is considered to be a German invention. This is hardly a chemical art, but it is probably better placed here than elsewhere.—*Royle, Arts &c. of India, page* 486. The Sealing wax made at Guntoor is very good, and, for a hot climate, better than the English wax, as it does not soften with the heat of the atmosphere.—*M. C. C.*

(7516) SEALS.

Cachets, Fr.	Petchafte, Ger.
Moohur, Guz. Hind.	Sigilli, It.
Sigillum, Lat.	Mohur, Pers.
Sellos, Port. Sp.	

Are stamps for impressing letter-wax, and other soft substances. They are usually formed of stone or metal, on which some device, &c. is engraved.—*Faulkner.*

(7518) SEBESTENS, Lindley's name for the order [illegible]ce.—*Eng. Cyc.*

(7519) SEBESTENS. Cordia Myxa.

Le[illegible] Hind.; Buhooari, Beng.

Sebestena, fruit and pulp of Cordia Myxa.—*Ben. Ph.* 294. These were formerly used in Europe but now by the native practitioners of the East only. The dried fruits are very glutinous, and are esteemed expectorant. The seeds of Cordia Myxa, are called Chakoon kee beenge, and deemed an infallible remedy in ringworm, the powder mixed with oil being applied to the eruption (Beng.—Dis.)—*Thirty five years in the East by Dr. Honig. p.* 343.

(7520) SECALE, a genus of Grasses, to which the cultivated Rye belongs. The flowers are arranged on a spike; the spikelets are 2-flowered, with a long stalked rudiment of a third floret, the glumes are subulate. In other respects this genus strongly resembles *Triticum*, to which the Common Wheat and Couch-Grass belong.—*Eng. Cyc.*

(7521) SECALE CEREALE, Rye, has the glumes 1-nerved and shorter than the spikelet; the rachis is very tough. This plant is extensively cultivated in Europe, and nowhere has been observed in a truly wild state, away from the possibility of escape from cultivation, being sown by the agency of man.—*Eng Cyc.*

(7522) SECAMONE, a genus of Plants belonging to the natural order *Asclepiadaceæ*, found in the warm parts of India, Africa, Australia, and in the West Indies. The name is probably derived from the Arabic Sukmoonya, as this is the proper name in Prosper Alpinus of the *Secamone Alpinii*, or *Periploca Secamone* of Linnæus. The genus *Secamone* is characterised by having a quinquifed calyx and corolla, the latter being rotate; stamineous crown 5-leaved, with the leaflets compressed laterally; pollen masses 20, erect; stigma coarctate at top; follicles smooth; seeds numerous, hairy at the umbilicus. The species form erect or climbing smooth shrubs with opposite leaves; the flowers are small, and the inflorescence in cymes, which are dichotomous, arising from between the petioles. Some of the species of *Secamone* secrete a considerable quantity of an acrid principle, which makes them useful as medicines. Thus the roots of S. *emetica*, being emetic in action, are employed as a substitute for Ipecacuanha; whilst the substance called Smyrna Scammony is said to be obtained from the Egyptian species, *S. Alpinii* of Rœmer and Schultes, the S. *Ægyptiaca* of Brown.—*Eng. Cyc.*

(7523) SECAMONE EMETICA. *Syn.* Periploca Emetica, Retz.

Grows common in the southern parts of the peninsula of India at the foot of mountains; a smooth twining shrub, leaves short stalked, veinless, smooth, varying from elliptical to narrow lanceolate, cymes interaxillary, shorter than the leaves. Roots acrid and emetic.—*O' Shaughnessy, page* 461.

(7524) SEDGES. Cyperaceæ. The *Cyperaceæ* may be called the Grasses of moist situations, and very closely resemble them in appearance; but they may readily be distinguished by their stems being solid often triangular, and their leaves with entire, not split sheaths. Though a few do secrete fecula in their tuberous rootstocks, as the Water Chesnut of the Chinese, &c., others secrete a little Volatile Oil, as *Cyperus*

longus and *rotundus*. They are mentioned here because the creeping rhizomes of *Carex arenaria*, and of a few allied species, are sometimes used medicinally, under the name of German Sarsaparilla —*Royle*. Sedges nearly resemble grasses in appearance, but grow usually in moist situations, and are distinguished from them by their angular stems. There are few of them useful for any purpose—not even for fodder. One of them, however, is famous as having yielded the Papyrus of the Egyptians, employed by them for making paper, ropes, and even boats; and of which the plant is so frequently represented in their Sculpture and paintings An Indian species of Cyperus (*C. tegetum*, Roxb.; *called Papyrus Pangorei* by Nees von Esenbeck), the *Madoorkati* of the Bengalees, which is extremely common about Calcutta and in Bengal, is very extensively employed for making the elegant, shining and useful mats for which the capital of India is famous, and which are frequently imported into Europe. Dr. Roxburgh states that the culms or stalks of the plant when green are split into three or four pieces, which in drying, contract so much as to bring the margins in contact, in which state they are woven into mats, and thus show a nearly similar surface on both sides. Specimens of the strips of this sedge were sent to the Exhibition of 1851, as well as mats made of them. These strips are tied up in bundles about four inches in diameter and four feet in length; and seem, besides their extensive use for mat-making to be well adapted for platting. The cotton-grass (*Eriophorum*) of Europe is a conspicuous ornament of turf-bogs and marshy moors, from having its seeds clothed at the base with a silky or cotton-like substance. With this, pillows are sometimes stuffed, and wicks of candles as well as paper, made. There is a species of the genus very common in the Himalayas, both in low valleys and at considerable elevations. This, Dr. Royle named *Eriophorum cannabinum*, in consequence of his finding it everywhere employed in making ropes for all ordinary purposes by the mountaineers. Its name, *bhabhur* and *bhabhuree*, has a considerable resemblance to that of the papyrus, considering that the *b* and *p* are letters so frequently interchanged for each other. All who have scrambled up the steeps of the Himalayas will remember the great support they have received from the toughness of the tufts of the bhabhur. Specimens of the dried leaves, made up into bundles about three feet in length, were sent to the Exhibition of 1851, from Beerbhoom. Also twine made from it: this, though rough, is strong and well fitted for ordinary purposes. Capt. Huddleston, in a paper on the Hemp and other fibres of Gurhwal, in the Himalayas ('Trans. Agric. Soc. of India,' viii, p. 272), mentions the Bhabhur as holding a conspicuous place, "from its extensive use and most abundant supply throughout the whole of the hills, affording a most economical substitute as an article of cordage, in lieu of others of a more costly and durable nature. All the jhoolas or rope bridges, which are erected over the large rivers where sanghas or wooden planked bridges cannot be made, on all the principal thoroughfares of that district, are constructed of this silky species of grass, the cables of which are of a considerable thickness. These rope bridges are a very safe means of communication over the large and rapid rivers intersecting different parts of the country, both for travellers and men with loads; and, where the footway and sides are properly laced with brushwood, afford an easy enough roadway for loaded sheep—but neither ponies nor cattle can travel over them. This grass grows abundantly in all the ravines of the sides of the mountains, and is to be had only for the cutting—but it is not of a very durable nature, though pretty strong when fresh made into ropes. It lasts about a twelvemonth only, or a little more, and the people in charge of the rope bridges are constantly employed in repairing and annually renewing the ropes and stays. The 'chinkas,' or temporary bridges of a single cable, upon which traverses a seat in the shape of an ox-yoke, are also sometimes made of this grass"—*Royle Ind. Fib. p.* 35.

(7525) The *papyrus* of the Egyptians belongs to this genus, and is still called *babier* in Syria. It is about 15 feet high; the exterior tunic of the stems cut in bands, and pressed, formed the paper of ancient Egypt and Europe; the leaves, which are several feet long, served for the same purpose, but were of inferior quality. This paper is but little liable to decay. Pliny, for instance, relates that the book of the laws of Numa Pompilius was found in Rome in a high state of preservation, after having been buried nearly six centuries in the earth.—*O'Shaughnessy, page.* 628.

(7526) SEDUM CÆRULEUM: Crassulaceæ. A species of succulent plants, with various coloured flowers, all of which should be grown separately in pots, in a light sandy soil mixed with brick rubbish, they are propagated by seed, these plants are well adapted for rock work.—*Riddell.*

(7527) SEED.

Beenge, Guz. Hind. | Vittooloo, Tel.
Tukhm, Pers.

In commerce, the grains of several species of gramina. Those of most importance, in a commercial point of view, are clover seed, flax or linseed, rape seed, mustard seed, hemp seed, and jingelly or sesamum seed.—*Faulkner.* In China, in the packing of seeds, they first gather the seeds from the plants, then put each kind, separately, into a small bottle, and then pack the whole with a little box, ready for being shipped to Europe or America.—*Fortune, page* 131.

(7528) SEKAKOY.

Sekakoy, Guz. Guz. Hind. Tam. Tel.

The name given in India to a long, flat pod, or legume, containing separate, small, oval, dark coloured seeds, considered by native practitioners a most valuable medicine. In taste it somewhat resembles the soap-nut, but is more acrid, less bitter, and has a singular pungency. It is extensively used in India for washing the head.—*Faulkner.*

(7529) SEMAL KA PHOOL. Flowers of the Bombax heptaphyllum, considered refrigerant. —*Genl. Med. Top. p.* 152.

(7530) SEMECARPUS, a very small and entirely Indian genus of Plants belonging to the natural order *Terebinthaceæ*, of which the name is derived from *σημεῖον*, a mark, and *καρπός*, fruit, from the remarkable property possessed by the juice of the fruit, whence it is commonly called Marking-Nut. The genus is characterised by having polygamous flowers; calyx 5-cleft; petals 5 oblong, sessile; stamens 5; disc urceolar; ovary free, sessile, girded by a tumid ring; styles 3; stigmas obtuse, emarginate. Nut compressed, heart-shaped, seated on a depressed thickened torus. Pericarp hard and thick, containing between the inner and outer layers cells full of a corrosive resinous juice.—*Eng. Cyc.*

(7531) SEMECARPUS ANACARDIUM. Marking Nut Tree.

Shayng cottay, Tam.	Jadi Chettoo, Chai bin,
Bhela, Hind	Burm.

S. Anacardium has long been known for the corrosive resinous juice contained in the nut. This juice is at first of a pale milk-colour, but when the fruit is perfectly ripe it is of a pure black colour and very acrid, and in both respects resembles that of several other plants of the same family, as in the Cashew-Nut, species of *Rhus*, and some of the varnish-trees. The juice is employed in medicine by the natives of India, and to mark all kinds of cotton cloth. The colour is improved and fixed by a mixture of quicklime and water.—*Eng. Cyc.* This common tree is of no value as timber. A considerable quantity of the nuts are exported from the Deckan, and Mysore, as a mordant. The juice is so acrid that wood cutters are unwilling to cut the tree until after it has been killed by ringing the bark.—*Rohde. Semecarpus anacardium* in Pegu is a middle-sized tree, common in the Pegu and Tounghoo Forests. Wood white coloured, adapted for fancy work and cabinet making.—*McClelland.*

(7532) SEMECARPUS ANACARDIUM.

The Oil.

Shayng cotty yennai, Tam.	Bhillawan ka tael, Hind.
Nellajiedie noona, Tel.	

The acrid and vesicating oil which is found between the two laminæ of the pericarp of the marking nut is collected and used, as a preventive against the attacks of white ants, and by native practitioners in rheumatic and leprous affections. By boiling the whole nut not divested of its pericarp, an oil is also obtained which acts as a blister, The preparation or collection either of the oil or acrid juice is liable to cause much irritation and inflammation of the hands, face, &c, of those engaged in the work.—*M. E. J. R.*

(7533) SEMECARPUS ANACARDIUM. Marking Nut, Malacca Bean.

The Nut.

Beladur, Arab.	Bellama, Bhecla, Hind.
Gheru, Can.	Shayng Cottay, Shayr-
Bellawane, Bhela, Duk.	aing cottay, Tam.
Bellama, Guz.	Nellajiedie, Jeedighen-
Bhallataka, Arushkara, Sans.	zaloo, Tel.

The tree bearing this nut (*Semecarpus Anacardium*), is a native of all the mountainous parts of India. The nuts are black, smooth, shining, and flattened on both sides. The acrid black-juice of the nut is employed by the natives externally to remove rheumatic pains, aches, and sprains, by rubbing a little over the affected part. It is also universally used for marking cotton cloth, whence its name of marking nut, the colour being improved, and prevented from running, by being mixed with lime water.—*Faulkner.*

(7534) SEMEN CONTRA, INDIAN.—Saheba—Undeveloped calices of Artemisa judaica.—*Ben. Phar. Semen-contra* is a well known and much esteemed anthelmintic, especially in the round and long worm of children, (*lumbricus teres.*) The action is heating and stimulant, dose 10 grs. to ½ a drachm finely powdered, in electuary with honey, or diffused through milk, and taken when the stomach is empty. In infusion or decoction the bitterness is quite disgusting; cathartics should either follow or accompany its use. The use of moxa, or of actual fire, to the surface of the body is a favourite practice in all savage and even half civilized nations. In China the down of the Artemisia Chinensis is set on fire, and the burning end applied directly to the part. In India a red hot *gool*, or hooka pastille, is usually employed. In Italy a small flame of hydrogen has been lately tried, and in Germany it is a common practice to place a particle of phosphorus on the skin, and then ignite it. The object in all is to effect counter-irritation, and the usual cases in which it is applied are chronic rheumatism, sciatica, neuralgia, deep seated diseases of the bones, cartilages or ligaments. In India *gools* are used by the native empirics for almost all diseases, especially for enlargements of the spleen and liver.—*O'Shaughnessy, page* 417.

(7535) SEMNOPITHECUS, F. Cuvier's name for a genus of Monkeys. The canines are much longer than the incisors; head round; facial angle more open than that of the Orang's; face

flat. Limbs very long in proportion to the body; anterior thumbs very short. Cheekpouches small or null. Callosities. Tail very long and slender.

Dental Formula;—Incisors, $\frac{4}{4}$; Canines, $\frac{1-1}{1-1}$; Molars, $\frac{5-5}{5-5}$ = 32.

F. Cuvier observes that the canines are often much larger than the rest of the teeth, and consequently than they are here represented. This is exemplified in the case of *S. Maurus*. Mr. Ogilby, in his 'Natural History of Monkeys,' alludes to the bezoars reported by many travellers to exist in the stomachs and intestines of the Asiatic monkeys, as confirmatory of Professor Owen's views; and adds that the bezoars produced by the monkeys of the Malay peninsula, and which can scarcely belong to a genus different from the *Semnopitheci*, are described as being smaller, rounder, and more powerful in their qualities than those obtained from ruminating animals.

(7536) SEMNOPITHECUS ENTELLUS, the Hoonuman (Houlman of M. Duvaucel) of the Hindoos, Lunger of the Hill Tribes. The young are remarkable for the disproportionate length of the extremities, the deliberate air of their movements and the tranquillity of their eyes and physiognomy generally. Face and hands black; body and limbs light gray or straw-colour; hair surrounding the face, and forming a projecting bandeau over the eyebrows; a peaked beard directed outwards beneath the chin. The colour always darker on the loins and along the spine, and becoming deeper as the animal advances in age, till finally the fur, becoming mixed with numerous black hairs, is of a rusty brown. The body at the same time becomes more developed and muscular, and the animal, when at its full size, is 4½ feet from the extremity of the muzzle to the origin of the tail, which is considerably longer than the body, of the same colour, and ends in a tuft of hair rather longer and darker than the general hue. It is a native of Bengal, the Himalayan Mountains, Nepaul, and Bootan. This monkey is remarkably interwoven with the religion of the country where it is found. M. Duvaucel has given an interesting account of the careful watch which the Bengalees kept over him to prevent his killing this sacred animal, holding a high place among the thirty millions of Indian gods, and to save himself from dying within the year, which, according to popular belief, is sure to be the fate of one who puts an Entellus Monkey to death. He was harangued by the Hindoos upon the danger of injuring animals which were no other than princes and heroes under the operation of the metempsychosis. Unmoved by their eloquence, and eager to possess a specimen, he levelled and brought down a 'princess.' But the acquisition was dearly bought. The ill-fated creature had a young one on her back, and, though shot through the heart, the mother exhausted her remains of life in throwing it into the branches of a neighbouring tree; then fell and expired at the feet of M. Duvaucel. It is but just to add that he mourned over the deed he had done. The remains of a species of quadrumanous animal allied to *Semnopithecus* were found by Captain Cautley and Dr. Falconer amongst the fossils discovered by them in the tertiary strata of the Sewalik Hills in the north of Hindoostan. ('Geol. Proc.,' 1838.)

(7537) SEMNOPITHECUS MAURUS, the Buding of the Javanese, Lutung utau Maure of the Malays and Europeans, Lotong of the natives of Sumatra. Dr. Horsfield describes this species as being on the whole of a stouter make than *S. melalophos*, and as having more robust extremities. One of the specimens in the Museum at the India House measures 2 feet 3 inches from the tip of the nose to the root of the tail. The face is regularly circumscribed by hairs, which are long, and closely applied to the head; the forehead, which is gradually sloping, is entirely concealed by them. The general facial character is a flatness above, and a protrusion of the maxillæ; but the appearance of the face differs greatly in old and young subjects. Dr. Horsfield states that the Budeng, or black species, is much more abundant than the red species, or Lutung of the Javanese (*S. Pyrrhus*); but the latter, both on account of its variety and comparative beauty, is a favourite among the natives. "The *Semnopithecus Maurus*," he continues, "is found in abundance in the extensive forests of Java; it forms its dwellings on trees, and associates in numerous societies. Troops, consisting of more than fifty individuals, are often found together. In meeting them in the forests it is prudent to observe them at a distance.

(7538) SEMNOPITHECUS MELALOPHOS. Brilliant yellow-red above, whitish below; a tuft of black hairs on the forehead in form of a bandeau; face blue. This is the Simpai of the Malays; and in this species the great length of body and slenderness of the extremities, so characteristic of the *Semnopitheci*, are manifested in the highest degree. It is found in the forests of Sumatra.

(7539) SENNA.

Suna, Arab.	Bootallapotaka, Amshun-atydivain-diva, Sans.
Sana-pat. Beng.	Nilaverei, Nilavaghei, Tam.
Nilaverie, Cyng.	Nayla tungadoo, Nila ponna, Tel.
Sene, Fr.	
Sennablater, Ger.	
Soonamukee, Guz. Hind.	
Senna, It.	
Cassia, Senna, Lat.	

The leaves of certain species of cassia, C. elongata; C. acutifolia; C. lanceolata; and C. obovata; all agree in certain properties; the odour of the leaves is heavy and peculiar, taste bitter, nauseous, and glutinous, powder yellowish green. At least eight varieties of senna leaf are known

in commerce in Europe; 1. The Senna palthe; 2. Senna of Sennaar, or Alexandria; 3. of Tripoli; 4. of Aleppo 5. of Moka; 6. of Senegambia; 7. the false or Arguel; 8. the Tinnevelly. The Senna palthe is prepared at Boullac, and is known to contain 5 parts of the Cassia acutifolia, 3 of C. obovata, and 2 of the Cynanchum oleæfolium. It is in this variety of the drug that the poisonous leaves of Coriaria myrtifolia have been found by M. Dublanc. The *Moka* senna is chiefly cultivated for exportation to India, where it is common in all the bazars. The other foreign varieties do not require particular notice. The Tinnevelly drug is in species identical with the Moka. In Egypt the senna harvest takes place twice annually, in April and September; the stalks are cut off with the leaves, dried before the sun, and then packed with date leaves. From all parts of Upper Egypt these packages arrive at the entrepot near Boullac, called *la Palthe*. The Palteers are tax agents of the Pasha, who has of course a monopoly of this trade; they sort, mix, and adulterate the drug, and pass it into commerce through Alexandria. —*O'Shaughnessy, p.* 307. Simmonds says that several varieties of Cassia, natives of the East are grown for the production of this drug. The dried leaves of *C. lanceolata* or *orientalis*, grown in Egypt, Syria, and Arabia, the true Mecca senna, are considered the best. In Egypt the leaves of *Cynanchum Arghel* are used for adulterating senna, *Cassia obovata* or *C. senna*, also a native of Egypt, cultivated in the East Indies, as well as in Spain, Italy, and Jamaica. It is a perennial herb, one or two feet high. In the East Indies there is a variety (*C. elongata*) common about Tinnevelly, Coimbatore, Bombay, and Agra, &c. Several of this species are common in the West India islands. The plants, which are for the most part evergreens, grow from two to fifteen feet high; they delight in a loamy soil, or mixture of loam or peat. The seed is drilled in the ground, and the only attention required by the plant is loosening the ground and weeding two or three times when it is young. The senna leaves imported from India are not generally so clean and free from rubbish as those from Alexandria. They are worth from 20s. to 27s. per cwt. in the Bombay market. The prices are—Alexandria, 1½d. to 6d. per lb.; East Indian, 2d. to 3d. per lb.; Tinnevelly, 7d. to 9½d. per lb. Senna is collected in various parts of Africa by the Arabs, who make two crops annually; one, the most productive, after the rains in August and September, the other about the middle of March. It is brought to Boulack, the port of Cairo, by the caravans, &c., from Abyssinia, Nubia, and Sennaar, also by the way of Cossier, the Red Sea, and Suez. The different leaves are mixed, and adulterated with arghel leaves. The whole shipments from Boulac to Alexandria, whence it finds its way to Europe, is 14,000 to 15,500 quintals. The quantities imported for home consumption were—

	From the East Indies.	Other places.	Total.
	lbs.	lbs.	lbs.
1838	72,576	69 88.....	142,114
1839	110,409	6,566.....	174,275

In 1840, 211,400 lbs. paid duty, which is now only 1d. per lb. In 1848, we imported 800,000 lbs. from India; in 1849, the total imports were 541,143 lbs. The imports into the United Kingdom were, in 1847, 246 tons; 1848 402 tons; 1849, 240 tons. Alexandrian senna (*Cassia acutifolia*). This species is said by some to constitute the bulk of the senna consumed for medical purposes in Europe. It is much adulterated with the leaves of *Cynanchum Arghel*, *Tiphrosia apollinea*, and *Coriaria myrtifolia*.

C. lanceolata and C. ethiopica furnish other species of the same article, the greater part of the produce of which finds its way to India through the Red Sea, Surat, Bombay and Calcutta, the imports into Calcutta, in 1849, having been 79,212 lbs. *C. obovata* furnishes the Aleppo and Italian drug. At least eight varieties of senna leaf are known in commerce in Europe—1. the Senna palthe; 2. Senna of Sennaar or Alexandria; 3. of Tripoli; 4. of Aleppo; 5. of Moka; 6. of Senegambia; 7. the false or Arghel; 8. the Tinnevelly. In Egypt the Senna harvest takes place twice annually, in April and September; the stalks are cut off with the leaves, dried before the sun, and then packed with date leaves. At Boulac, the drug is sorted, mixed, and adulterated, and passed into commerce through Alexandria. Alexandrian senna, according to Mr. Jacob Bell ("Pharmaceutical Journal," vol. 2, p. 63), contains a mixture of two or more species of true senna. It consists principally of *Cassia obovata* and *C. obtusata*, and according to some authorities it occasionally contains *C. acutifolia*. This mixture is unimportant, but the *Cynanchum Arghel*, which generally constitutes a fifth of the weight on an average, possesses properties differing in some respects from true senna, and which render it particularly objectionable. The Tinnevelly senna, that most esteemed by the profession, is known by the size of the leaflets, which are much larger than those of any other variety; they are also less brittle, thinner and larger, and are generally found in a very perfect state, while the other varieties, especially the Alexandrian, are more or less broken. The leaves of the Cynanchum are similar in form to those of the lanceolate senna, but they are thicker and stiffer, the veins are scarcely visible, they are not oblique at the base, their surface is rugose, and the colour grey or greenish drab; their taste is bitter and disagreeable, and they are often spotted with a yellow, intensely bitter gummo-resinous incrustation. Being less fragile

than the leaflets of the true senna, they are more often found entire, and are very easily distinguishable from the varieties which constitute true Alexandrian senna. In their botanical character they are essentially different, being distinct leaves, not leaflets, which is the case with true senna.—*Simmonds.*

(7540) *Senna.* A fine specimen of "Tinnevelly senna" cultivated near Cape Comorin, was noticed as of a superior quality. It is satisfactory to remark, that senna grown in the Southern provinces of the Madras presidency is highly esteemed in Britain, and preferred by many to all other sorts, as being both cheaper and purer.

(7541) *Senna, Indian,* LEAVES OF CASSIA ELONGATA. *Ben. Ph.* 224.

(7542) *Senna leaves,* raised at Dapooree from Tinnevelly Seed, has been found equal to the best Arabian Senna.—*Spry's Suggestions p.* 36. Senna leaves, the picking in Guzerat of sowings in August, is made in September: and Dr. Burn states that the virtues of the leaf, depend greatly on the time of the picking.—*Spry's Suggestions, p.* 43.

Senna has been distinctly known only since the time of the Arabs; but they refer to the legumes only, though the leaves have long been employed in the East. There is, however, great uncertainty respecting the species of Cassia which yield the diffrent commercial varieties. This is owing partly to all the Senna countries not having been thoroughly explored, and partly to species having been formed from imperfect specimens, and others from leaves collected out of different samples of the Sennas of commerce. The following species seem to be clearly distinct. Dr. Royle has changed the name of Forskal's *C, lanceolata,* in consequence of the great confusion which has arisen from this name having been applied by so many authors to the sharp-leaved Senna, which is imported in such large quantities both from Arabia and Egypt, and to which he restricts it.

1. C. FORSKALII (C. lanceolata, *Forsk.* and *Lindley,* Fl. Med. p. 259). Leaflets in 4 or 5 pairs, never more: oblong and either acute or obtuse, not at all ovate or lanceolate, and free from downiness even when young; the petioles have *constantly* a small round brown gland a little above the base. The pods are erect, oblong, tapering to the base, obtuse, turgid, mucronate rather falcate, especially when young, at which time they are sparingly covered with coarse scattered hairs. (Lindl. *l. c.*) Collected by Dr. S. Fischer in palm-grounds in the valley of Fatme, flowering at the end of February. Forskal describes this as being distinguished "glandula supra basin petioli." It was found by him at Surdud and about Mor. It is called *Suna* by the Arabs, and probably yields some of the Arabian Senna of commerce.

2. CASSIA LANCEOLATA (taken from Dr Royle's "Illustrations of Himalayan Botany." t. 37.) This is a bushy annual, of about 2 to 3 feet in height, extremely leafy, and of most luxuriant inflorescence in a cultivated state. The stems are erect, round, smooth, a little flexuose towards the apex. The leaves alternate abruptly pinnate. The leaflets 5 to 8 pairs, with short petioles, ovato-acute in the lower and lanceolate-acute in the upper parts of the plant, "slightly mucronulate, smooth above, rather downy beneath (especially in young leaves) with the veins turning inwards and forming a flexuose intramarginal line; petioles without glands; stipules softly spinescent, semihastate, spreading, minute." Racemes axillary and terminal, erect, rather longer than the leaves. Ovary linear, downy, falcate, with a smooth recurved style. Legumes (3) pendulous, membranous, flat, only slightly protuberant over the seeds, oblong, sometimes elliptical, nearly straight, with the upper margin a little curved, tapering abruptly towards the base, and rounded at the apex, of a brown colour containing from 5 to 8 white rugose seeds (2). These are figured by Gærtner, ii. t. 146. It is probably the *Cassia medica* of Forsk. p. cxi., and agrees with his specimen of "Senna Meccæ Lohajæ invenieba-tur foliis 5—7 jugis, lineari-lanceolatis," p. 85 of which Forskal states large quantities are yearly exported from the district of Abu-atiseh to Jidda. This species includes:

a. Tinnevelly Senna, cultivated by Mr. Hughes in the south of India; also that cultivated by Dr Royle at Saharunpore. *C. lanceolata,* Royle, Illus. Bot. t. 37. and by Dr. Wight near Madras v. fig. 60, B. and spec. in Brit. Mus. It is the *Cassia officinalis,* of Gært. and Roxburgh, Fl. Ind. ii. p. 346, which name ought to have been retained or the above *C. medica* Forsk. instead of *C. elongata* being coined, especially as this was formed from the leaves of a cultivated Indian Senna found in commercial samples. It is cultivated by Dr. Gibson, near Poona.

Dr. Burns writes that he has found the lanceolate Senna wild near Kaira in Guzerat. His cultivated specimens, if picked, would form good Senna.

b. C. lanceolata of most authors. *C. acutifolia* Hayne, ix. t. 41, Nees and Eberm. t. 345. St. and Church. Pl. 30 as C. Senna. These best represent the form of Alexandrian Senna (v. 60. A. a small leaf), and specimen in Brit. Mus. from Senaar. (*Kotschy.*) It is found in the valleys of the desert to the south and east of Syene or Assouan. and collected for the trade to Cairo forming 3-5ths of Alexandrian Senna.

c. C. acutifolia, called of Delile, Esenbeck and Eberm. t. 346. (fig. 60. c) The leaflets are narrower and more tapering towards the apex than the foregoing as might be expected in poorer soil and drier climate. Some of the Indian

specimens in Dr. Rottler's Herbarium closely resemble this variety; also African specimens from Tajowra to the south of the Straits of Bab-el-Mandeb.

Dr. Royle is unable to distinguish these by any permanent characters, nor dried Senna-leaves cultivated at Saharunpore from good specimens of *Bombay Senna* (that is, ordinary Indian Senna) imported into England from India: nor these from *Suna Mukki*, sent him by Dr. Malcolmson from Aden, and which he states are "the produce of Africa, but in appearance exactly resemble the Arabian Suna. In the market both are sold as one kind, and bring the same price."

3. C. OVATA of Merat, Dict. de Mat. Med. b. 613. *C. æthiopica*, Guibourt. Is probably a distinct species, as it is said to have a gland at the base of the petiole and another between each pair of leaflets. The leaflets are in 3 to 5 pairs, exactly oval acute, slightly pubescent below; the follicles are thin, pale yellow-coloured, 1-3rd smaller than those of *C. obovata*. It is said to be found both in Nubia and Fezzan, and to furnish exclusively the Senna of Tripoli, Sene de Tripoli. It is extremely like a variety of *C. lanceolata*. The figure of C. Senna in Stevenson and Churchil, Med. Bot. t. 30, quoted by Dr. Pereira as representing this plant, is referred to by Dr. Lindley as a good representation of C. acutifolia of Delile. But Merat and De Lens say of it: "Nous ne le connaissons que par les fruits qu'on en voit dans la commerce." M. Guibourt calls it *C. ætheopica*; but instead of referring to *C. lanceolata* of Calladon, Pl. xv. f. c as representing this species, he says that it is exactly represented by the Sene de Nubie of Nectoux, pl. 2

4. C. OBOVATA *Colladon*. Hayne, ix. 42. Nees and Eberm. 347. Diffuse herbaceous plant. Leaves equally pinnate, glandless. Leaflets 4-6 pairs (somewhat villous, Roxb.) obovate, obtuse, but slightly mucronate, unequal at the base, the terminal pair more cuneate and larger. Stipules triangular, narrow, and tapering, rather stiff and spreading. Flowers yellow, in racemes. Bracts ovate, cordate, acuminate, concave, single-flowered. Legumes broad, membranous, smooth, lunate in shape, rounded at each end, with an elevated crest over each side on both valves, so as to form an interrupted ridge along the middle of each valve. Seeds 6 to 8, wedge-shaped, rugose as in C. lanceolata.—A native of Africa, from Senegal (*Fl. de Senegambie*) to the Nile; found in Fezzan by Dr. Oudney (*R. Brown*), in Egypt from Cairo to Assouan, Nubia: found in the Adel country near Sultalli (*Mission to Abyssinia*); Desert of Suez; Syria; dry parts of India, as Kaira (*Burns*); Guzerat, Dekkan (*Col., Sykes*), near Delhi, and Valley of Rungush, near, Peshawar (*Falconer*); high dry uncultivated lands of Mysore (*Roxburgh. Wight*). It has been cultivated in Italy (*Sene d' Italie*), and forms 3-10ths of Alexandrian Senna.

This species is very distinct, in its obtuse obovate leaves and crested legumes, from the preceding acute-leaved species. *C. obtusa* Roxb: was probably described from young legumes, as Dr. Royle, like Dr. Lindley, has compared good specimens from Mysore with others from Africa. The *obtusata* (fig 60 H.) of Hayne does not seem to differ sufficiently from his *C. obovata* (fig 60, G.) It is possible, however, that there are two very similar species in Africa. Mr H. Grant, late of the India House, has favoured Dr. Royle with a specimen in flower, collected by him in February at Philæ, which has upon it *both* obovate (H.) leaflets and some which are ovate and acute (G)! Lieut. Wellsted's collection contains a specimen from the coast of Arabia, of which the leaflets are obtuse, elliptic, and hairy.

The Sennas of commerce may be arranged as follows.

1. TINNEVELLY SENNA, first cultivated in the district of that name, in 12° of N. lat. by the late Mr. Hughes, from seed probably obtained from Arabia or picked out of *Suna Mukki*, as was done by Dr. Royle when he cultivated Senna at Saharunpore. (*v.* Himal. Bot. p. 186, t. 37, and Trans Med. Soc. of Calcutta, v. p. 433). That author also grew Senna from Tinnivelly seed sent to him by Sir C. since Lord Metcalfe; but he did not find the smallest difference between the two when grown in the same situation. The Tinnevelly Senna is well-grown and carefully picked; the leaflets are of a fine, rather lively green colour; thin, but large, being from one to two inches in length, truly lanceolate. This kind is "highly esteemed in Britain, and is quickly displacing all the other sorts in Edinburgh, and many other cities in Britain." (Christison.) Dr. A. T. Thomson says of it, it is mild in operation, certain as a purgative, and operates without griping. It is now cultivated by Mr. Hughes' successor.

Saharunpore Senna, the same kind of Senna cultivated at Saharunpore, differed only in the leaflets being smaller, as might be expected from the more northern latitude (30°). These Dr. Royle prescribed in the hospitals at Saharunpore, and found them effective as a purge, and operating without producing inconvenient nausea or griping, Mr. Twining, after trying them in forty-five cases in the General Hospital at Calcutta, says, in his report to the Medical Board: "From these trials, I am disposed to consider the Senna now under trial equal to the best I have ever seen."

Madras Senna. Senna is now imported also from Madras, the produce of that Presidency. In 1843-44, I find 11,536 lbs. were exported to this country, having been previously imported into Madras from Tinnevelly, where it is cultivated by the natives, and is of the same nature as Mr.

Hughes' Senna, though not so well grown nor so carefully picked. Dr. Christison says of it the leaflets are longer than those of Bombay Senna, and not so taper-pointed, but otherwise differ only in being better preserved, and being more active, are more esteemed.

Dr. Searle, in a communication to the India House, says of this Senna, that "now furnished to the profession of the Madras Government is in my experience quite as good as the Alexandrian," "every leaf of the Indian being of the genuine spear-shaped species."

2. BOMBAY or Common Indian SENNA, *Suna Mukki* of the natives, is first imported into Bombay from the Arabian Gulf:

319,728 lbs. in 1837-39.	570,426 lbs. in 1838-39.
Re-exported to Great Britain,	262,284 lbs. in 1838-39.

That this Senna, forms a large, if not the largest proportion of what is consumed in this country, is not only evident from the above importation, but also from a comparison with the whole quantity of the other Senna imported, as given by Dr. Pereira.

	1838.	1839.
From East Indies	72,576 lbs.	110,409 lbs.
From other places	69,538 ,,	63,766 ,,

Some of this Senna is no doubt produced in Africa, as stated above by Dr. Malcolmson; a good deal of it in Arabia, probably by *Cassia lanceolata*, and some perhaps by *C. Forskalii*. The leaflets are thin, lanceolate, usually entire, about an inch or an inch and a half in length, narrower than either the Tinnevelly or Saharunpore Senna, probably from growing in a poorer soil and drier climate. They are of a pale green colour, often with dark brown-coloured leaflets intermixed, also some pods, and many leafstalks, with occasionally other impurities. The good specimens of this Senna are, however, of excellent quality, and its commercial and medical value would be much increased, if the finest leaflets were picked out. It is in constant use in hospital practice in India, and generally highly approved of. Dr. Royle prefers them for all purposes to the following kind as found in commerce.

3, ALEXANDRIAN SENNA is an excellent kind, when the genuine lance-shaped leaflets have been picked out; but that commonly employed in England is a mixed and very impure kind, being made up of the leaflets, much broken, of *C. lanceolata* and of *C. obovata*, with some pods and broken leaf-stacks, and also with leaves of other plants. It should be used only after having been carefully picked, as directed in the E. P. Picked Alexandrian Senna is of a pale green colour, with a faint smell. The leaflets are broad-lanceolate, the two sides unequal; they are thicker and shorter than the Indian Sennas.

The lanceolate Senna of Upper Egypt, Nubia, and Senaar, yields two crops annually, the plants being cut down in spring and autumn, dried in the sun, when the leaves are stripped off, packed in bales, and sent to several *entrepots*, and finally to Boulac in the vicinity of Cairo. Of the lanceolate Senna *five* parts are here mixed with *three* parts of the leaflets of *C. obovata*, brought from other parts of Egypt and even from Syria, and also with leaves (*two* parts) of *Cynanchum Argel*. This mixed Senna is that exported from Alexandria. On the Continent a further addition is made of the leaves of *Colutea arborescens* and of *Coriaria myrtifolia*.

Dr. Pereira states that, "under the name of *heavy senna* he has met with *argel* leaves, which were sold at a higher price than ordinary senna," and Dr. Christison mentions what indeed may often be seen, that is, Argel leaves left intermixed even in what is called Picked Alexandrian Senna. This Senna is often called "Sene de la Palthe."

4. TRIPOLI SENNA, is brought from Fezzan to Tripoli. This has the general appearance of Alexandrian Senna, but is less esteemed, though it is a more pure Senna, probably because the leaflets are more broken down, and all the leaf-stalks have not been removed. The leaflets are shorter and less pointed than in lanceolate Senna —indeed, more ovate; hence this Senna is said to be produced by *C. ovata* (æthiopica); but it also contains leaflets of *C. obovata*, which species was found in Fezzan by Dr. Oudney.

5. ALEPPO SENNA is now seldom imported into Great Britain. It consists of the leaflets of *C. obovata*, as do some other kinds, such as ITALIAN SENNA. Dr. Ainslie says that the *obovate* was the only kind of Senna met with in India, meaning the Peninsula of India; for it is not met with in the Bengal Presidency; nor, according to Dr. Searle, is it used in that of Madras at the present day. It is less effective as a purgative, and apt to create nausea and griping.

Adulteration. Commercial Senna is prepared for use by picking out the leaflets, and rejecting the leaf-stalks, also extraneous matter, as dust, date-stones, &c., as well as the leaves of the other plants. The legumes, however, possess the cathartic properties of the leaves to a considerable extent, and were alone used by the original Arabs; and there is no reason to believe that the stalks are inert. The most important adulterations are, however, the leaves of other plants. Those of the *Argel* (D.) may be distinguished by being lanceolate, equal on the two sides of the midrib, thick, leathery, and paler. They operate very dubiously as a cathartic, but occasion griping and protracted sickness. (*c.*) Those of *Tephrosia Apollinea* (F.) are obovate downy, and the veins proceed transversely from the midrib to each margin of the leaf without forming a marginal vein. The leaves of *Colutea arborescens*, or Bladder Senna, are ovate, but equal at the base. Those of *Coriaria myrtifolia* (E.) are astringent, usually broken down, and

marked on each side of the midrib with a strong lateral nerve. As the systematic adulteration of Senna in Egypt with the leaves of other plants is objectionable, and has been so noticed by the Pharmaceutical Society, the most efficient method of stopping it would be to purchase only the pure African and Arabian Sennas which come to us by Bombay, instead of (unless it has been picked) that which is called Alexandrian from its place of export (*v.* P. J, ii. p. 63.) In India a good substitute for Senna is afforded by *Rae Suna*. (*v.* COMPOSITÆ.)—*Royle, p.* 361.

(7543) SENSITIVE PLANTS is a term commonly applied to those species of plants that possess the property of visibly moving their leaves when they are touched or otherwise stimulated. This term is not applied generally to plants in which any movements can be observed; for the power of moving under the influence of certain external stimulants is a very general property of the tissues of plants, and especially of the flowers. There are a great number of species of plants of various families, that possess the power of moving their leaves under the influence of a slight touch; that which is best known is a plant belonging to the order *Leguminosæ*, called *Mimosa pudica*. It is a native of tropical climates in moist districts, where it is exposed to a temperature of between 70° and 80° Fahr. It is in its native districts where its excitability is seen to the greatest perfection. A knock upon the ground at a short distance from the plant is sufficient to produce an influence on the leaves; and Von Martius says, that at Rio Janeiro the falling of horses' feet by the way is sufficient to set whole masses of Mimosas in motion. When in England, the motions of the plant are always best displayed in high temperatures. The movements are not alone produced by mechanical irritants, for if various corrosive substances, as bichloride of mercury, sulphuric acid, caustic potash, &c., are applied to the knots of the joints, the same phenomena are observed. The removal of the plant to a higher temperature will produce the same result, as well as exposing it to a lower temperature or a draught of cold air. They are destroyed by the application of chloroform and other anæsthetic agents. Besides the *Mimosa pudica* there are several other species belonging to this genus that possess the same property, though not in so remarkable a degree. Amongst them may be named *M. Sensitiva, M. viva, M. casta, M. asperata, M. quadrivalvis, M. pernambucana, M. pigra, M. humilis, M. peltata, M. dormiens.* Species of other genera of the same natural order *Leguminosæ* exhibiting these movements are *Smithia sensitiva, Æschynomene Indica, Æ. pumila*, and *Desmanthus stolonifer*. The locust tree when its branches are roughly shaken closes up its leaves, and the same has been observed of *Gleditschia triacantha*, and it is probable that close observation during hot weather would prove that other leguminous plants possess this property. Another family of plants that exhibit sensation when touched or stimulated is *Oxalidaceæ*. The *Oxalis sensitiva*, called by De Candolle on account of its sensitive properties *Biophytum*, has long been known to possess this property. *Averrhoa bilimbi* and *A. carambola* are both plants belonging to *Oxalidaceæ*, and have been described by travellers as possessing the property of folding their leaves on the application of a stimulus. But it is not only in these species that this property resides, for Professor Morren of Liege has observed it to occur more or less in all the species of the genus *Oxalis*. His observations were first made on the *Oxalis stricta*, which, if hit smartly on a warm day, will contract its leaves and assume a position as in the ordinary sleep of the leaves of these plants. He has also observed the same movements in *O. Acetosella* and *O. corniculata*, and many extra-European species. The movements in these plants consist in the folding up of their leaves, so that the two halves of the leaf approach each other by their superior surface. The midrib is also slightly bent, so that its inferior surface presents a convexity; and the petioles of the leaflets bend downwards, so that the leaf, when irritated, becomes dependent. (Morren, 'Notes sur l'Excitabilité et le Mouvement des Feuilles chez les Oxalis,' in the 6th volume of the 'Bulletins de l'Académie Royale de Bruxelles.') In the family *Droseraceæ*, or Sun-Dews, are some plants which exhibit a considerable amount of irritability. The leaves of *Dionæa muscipula*, or Venus' Fly-Trap have the remarkable property of contracting upon insects that may happen to alight upon their surface. None of the Sun-Dews inclose insects in their leaves in this manner, but the surface of their leaves is covered with long hairs, which secrete a viscous matter. When any insect settles upon the leaf, it is entangled with the viscous secretions; and before it has time to escape, the hairs exhibit a considerable degree of irritability, and curving round, pin the animal down on the surface of the leaf. Other instances of vegetable irritability occur in the *Berberis vulgaris, Mimulus*, and *Stylidium.—Eng. Cyc.*

(7544) SEPIADÆ (Σηπία), a family of Cephalopodous *Mollusca*, including the forms which are ordinarily known under the name of Cuttle-Fishes. Dr. Leach divided the group of Cuttles into two families, the Octopods and the Decapods. The forms belonging to the first division are described under the article OCTOPODA.

(7545) The *Decapoda* are thus defined. Under this division are placed the *Teuthidæ*, or Calamaries, and the true *Sepiadæ*, or Cuttle-Fishes, properly so called.

(7546) *Sepioteuthis* (De Blainville).

(7547) *S. Sepiacea.* This species is figured in the article CEPHALOPODA under the name of *Sepia officinalis*, to which however it bears a very close external resemblance, so close indeed that authors generally place it immediately before that species. Thirteen species of the genus *Sepioteuthis* have been described. They are inhabitants of the West Indies, the Cape, the Red Sea, Java, and Australia.

(7548) *Loligopsis* (Lam.) There are eight species of this genus found in the North Sea, Atlantic, Mediterranean, India, Japan, and the South Seas.

(7549) *Onychoteuthis* (Lichtenstein).

There are about six species of *Onychoteuthis* found in the Atlantic, Indian, and Pacific oceans.

(7550) *Sepia* (Lam.)—Animal with an oblong depressed body, with two narrow lateral fins extending its whole length; mantle free at its anterior margin; the acetabula supported by horny hoops with the margin entire or very minutely denticulated.

(7551) *Sepia officinalis.* This is the Common Cuttle-Fish, so well known on our coasts, and whose shell is so often thrown up by the waves on the beach. The ink (nigræ succus loliginis) is common to this and other species of cephalopods. This fluid is not only ejected as a defence to colour the water in order to favour the escape of the animal, as was well known to the ancients (Oppian, 'Halieut.,' iii.; Pliny, 'Nat. Hist.,' ix. 29), but as a direct means of annoyance. That the juice was used by the ancients as ink is evident from many passages: we content ourselves with a reference to that above given, and to the lines in the graphic description of the idler by Persius. ('Sat.' iii., lin. 10, et seq.) The flesh of the naked cephalopods was rather esteemed of old, as it is indeed now in Italy and other countries. Aristotle declares that these animals are in the highest season when pregnant, and those who wish to taste a cuttle-fish sausage, will find a receipt for making that savoury viand in Athenæus. Mr. F. D. Bennett states that the Fe, or Cuttle-Fish, is considered a luxury by all classes of the Sandwich Islanders and that when fresh and well cooked it is an excellent food, and in consistence and flavour not unlike the flesh of a lobster's claw. ('Narrative of a Whaling Voyage round the Globe,' London, 1840.)

(7552) SERENGE, a Dyeing Seed.

(7553) SERGE. A quilted woollen cloth, made in Devonshire and other parts of England. —*Faulkner.*

(7554) SERISSA. ACACIA SERISSA. In China, the Serissa is cultivated around flower beds and parterres like the box.—*Fortune.*

(7555) SERON. A kind of package, formed of pieces of wood, fastened with hides.—*Faulkner*

(7556) SEROONAVALPOO. A drug.

(7557) SERPENTINE, a rock regarding whose origin geologists have differed. It is described as an irregularly over lying mass in the Lizard district of Cornwall, as a dyke at Portsoy, and as nodular aggregations in the granite of Aberdeenshire. The relation in which it stands to Diallage Rock (a compound of diallage and felspar) is very intimate, both in the Alps, in the Shetland Isles, and in Cornwall. In fact the composition of these rocks is scarcely more different than may be seen between largely crystallised and fine-grained greenstone. Serpentine is a very handsome stone when polished. Beautiful specimens from Cornwall, and other parts of England and Ireland, may be seen in the Museum of Economic Geology, London. When mixed with limestone it constitutes the Verd-Antique Marble. It does not wear well, although at first it receives a fine polish. Chromic iron is usually found disseminated through it. Dr. Jackson of America has shown that Epsom salts or sulphate of magnesia may be profitably manufactured from Serpentine. —*Tomlinson.* One species called noble serpentine, green and translucent, is valued as an ornamental stone. (*Waterston*)—*Faulkner.* Precious serpentine exists in the Hookhoong valley, north-west of Ava, whence it is exported to China, and brought into the southern parts of the empire, but it has not yet been discovered in the Tenasserim provinces.—*Mason.*

(7558) SERRANUS, a genus of Fishes belonging to the family *Percidæ.* It has a single elongated dorsal fin, the rays of the anterior portion spinous, the other flexible; branchiostegous rays 7; small teeth in both jaws on the palatine bones and the vomer, some elongated teeth among the smaller ones; cheeks and operculum covered with small scales; preoperculum serrated; operculum ending in two or three flattened points projecting backwards.—*Eng. Cyc.*

(7559) SERRATULA ANTHELMINTICA.
Worm Saw-wort Somraj, HIND.

Somraj Grows wild in Kotah.—*Genl. Med. Top. p.* 206.

(7560) SERRURIA. PROTEACEÆ. This genus of plants require the same treatment as the Protea. —*Riddell.*

(7561) SESAMUM (Σησαμον), a genus of Plants belonging to the natural order *Sesamaceæ* sometimes called *Pedalineæ*, containing only few genera and species. It is distinguished by having a 5-parted calyx; corolla with a short tube; bell-shaped throat; and the limb quinquifid, somewhat bilabiate. Stamens 4, didynamous, with the rudiments of a fifth stamen; stigma bilamellate; capsule oblong, 4-celled, 2-valved; seeds numerous. The species, though now cultivated in many countries, are supposed to have been originally natives of India. They form

annual plants, with opposite and alternate leaves, and axillary solitary flowers. The species are by some considered to be five in number, that is, *S. orientale, S. Indicum, S. luteum, S. laciniatum,* with *S. radiatum,* said to be a native of Guinea. Others consider them all to be varieties of one species. These are cultivated in various countries, but especially in India, Egypt, and Syria. They have also been taken to the West Indies, where the plant is called Banglo and Oil-Plant. Sesamum seeds are sometimes added to broths, frequently to cakes by the Jews, and likewise in the East.—*Eng. Cyc.* Dr. Wight gives Sesamum laciniatum and prostratum and Voigt gives S. Orientale with a variety. There seems, however, to have been considerable confusion arising from various names having been given to varieties of the same plant, viz: the S. Orientale of Roxburgh, to which we adhere, taking Voigt's Botanical names and Roxburgh's description.

(7562) SESAMUM ORIENTALE, Roxb. *Fl. Ind. Vol.* III. *p.* 100. Sesamum indicum, Linnæus. S. Trifoliatum, Mill. dict. No. 3. S. Luteum, Retz. S. Laciniatum, Willd.

An annual plant growing all over India, but cultivated in Egypt, the Levant, West Indies and South America.—*Voigt.* This species or variety is by far the most generally cultivated in the warmer parts of Asia. It is annual and in a good soil grows generally to be about three or four feet high. Roxburgh never found it in a wild state, (*Roxb.*), but Dr. Riddell tells us that in the Dekhan, the Sesamum Orientale or Gingelie Plant is a common plant springing up in waste places, and flowering towards the close of the rains.—*Riddell.* Roxburgh states that his figure of this plant, called Sesamum indicum by Linnœus, is the *Krishna til* of the Hindoos, which Roxburgh regards a variety of his S. Orientale. It is larger, more ramous, the stem and branches tinged with a rusty reddish colour, the leaves a darker green but in form and structure the same. The flowers are deep tinged with red and seed of a darker colour. Great difference, however, appears, in the seed and harvest time, Sesamum Orientale being sown in Bengal in February, and the crop got in three months afterwards, so that the dues and the little remaining moisture of the earth, are the only sources of humidity by which it can benefit, as this is generally a period of drought. *Sesamum indicum* is sown on high places, about the beginning of the rains, June, and the crop cut down in September.—*Roxburgh.* It will be seen from the above that there are two spiecies or strongly marked varieties of this plant, under cultivation. It may be said indeed, that the Sesamum is extensively cultivated in Southern Asia, for the oil, which is expressed from the seeds which are slightly oval, small, tasteless and inodorous, and that there are two kinds distinguished, *black* and *white* or *yellow*, which possess the same properties, and in commerce are met with both in a mixed and separate state. Gingelly seed is largely exported to England and France, but in India, this oil is perhaps consumed by the natives of India to a greater extent than any other and is second only to cocoanut oil in its importance as an article of commerce. It is extensively cultivated throughout the whole of the Madras Presidency, and has been exported from Madras as follows.

Gingelly Seed.

Years 1847-48.	Year 1848-49.
Qr. 17,518...Rs 160,134	Qr. 8,594.....Rs. 1,02,726
Years 1849 50.	Years 1850 51.
Cwt. 1,44,125 Rs. 299,412	Cwt. 2,27,779...Rs 4,37,185
Years 1851-52.	Years 1852-53.

Gingelly Oil.

Year 1847-48.	Year 1848-49.
Gl. 19,520.....Rs. 14,766	Gl. 14 686. .....Rs. 11,535
Year 1849-50.	Year 1850-51.
Gl. 52,721.....Rs. 36 294	Ge. 77,232.....Rs. 48,605
Year 1851-52.	Year 1852-53.
Gl. 46,196.....Rs. 26,722	Gl. 72,607.....Rs. 43 608

Of the gingelly seed exported from Madras in 1852-53, the United Kingdom received cwt. 12.713—Ceylon, cwt. 590—France, cwt. 2,87,225—Pegue, cwt. 741—Bombay, cwt, 113—Malacca, cwt. 33 and Travancore, cwt: 148. Of the quantity of oil (72,607 gals.) exported in the same year—gals. 42,043 were shipped to the United Kingdom—gals. 2,963 to Ceylon—gals. 4,232 to Mauritius and Bourbon—gals. 19,698 to Pegue—gals. 46 to Bengal—gals. 27 to the French (Indian) ports, and gals. 3,593 to Malacca.

Mode of preparation.—The great disparity of color observed in the specimens of this oil is to be attributed to the mode of preparation. The method sometimes adopted is that of throwing the fresh seeds, without any cleansing process, into the common mill, and expressing in the usual way. The oil thus becomes mixed with a large portion of the coloring matter of the epidermis of the seed, and is neither so pleasant to the eye, nor so agreeable to the taste, as that obtained by first repeatedly washing the seeds in cold

water, or by boiling them for a short time, until the whole of the reddish brown coloring matter is removed, and the seeeds have become perfectly white. They are then dried in the sun, and the oil expressed as usual. This process yields 40 to 44 per cent. of a very pale straw colored sweet smelling oil, an excellent substitute for olive oil.

Uses.—In India, it is chiefly used in cookery, in anointing the person, for making soap, and for burning in lamps. In England, it is chiefly used for the manufacture of soap, and for burning in table-lamps, for which it is better suited than cocoanut oil, owing to the lower temperature at which it congeals. *Price.*—Value in England (January 1855) £47.10 per ton. In different parts of the Madras Presidency the price of this oil varies from Rs. 1 5 0 to Rs. 6 0 0 per maund of 25lbs In S. Arcot it is procurable at Rs. 27 12 5 per candy. The prices per maund of this oil, at the undermentioned stations, for the quarter ending 31st October 1854, were as follows.

Arcot	Rs.	3	8	0	Madura, ...	Rs.	5	8	3
Bangalore, ...	„	3	7	3	Mangalore, ...	„	4	1	8
Bellary, ...	„	3	2	0	Nagpore, ...	„	1	12	0

Second sort Gingelly Oil, erroneously called "Rape," (Kharasance yelloo), is obtained from the red seeded variety.—This oil differs but little from the one above mentioned. In Tanjore, it is procurable at Rupees 3 0 0 per maund.

The following particulars concerning the two varieties of plant, yielding this important oil have been furnished by F. Copleston, Esq., Rajahmundry.

First sort Gingelly. The gingelly seed *par excellence* is the produce of the plant, which is sown in the month of March, after the rice crop, and is irrigated twice, once at sowing, and once afterwards. The seed which is *black*, and is called 1st sort gingelly, from the fact of its yielding the largest per centage of oil, ripens in May, and sells at the rate of Rs. 60 per candy of 500 lbs. The oil obtained from both varieties, sells at the same price, viz. Rs. 2 14 6 to 3 per maund of 25 lbs. according to quality.

Second sort Gingelly is sown in June, and produces a red seed. The plant although a little larger resembles in most respects the former, it has, however, a somewhat longer leaf, and the flower differs a shade or two in color. A candy of 500 lbs. of this seed sells at Rs. 57 8 0. The price of the oil is the same as that of gingelly. This seed has of late been exported to France, in consequence of which the present price is double what it was three years ago.—*M. E. of* 1855.

It will have been seen that of this small annual plant there are two varieties or according to some, species. Sesamum orientale, the common sort; and S. indicum, a less robust kind, cultivated at a different season, both natives of Southern Asia. S. indicum bears a pale purple flower, and S. orientale has a deep red blossom. It is the latter which is chiefly grown in the Peninsula, and the seeds afford the Gingelly oil or til ka tael already extensively known in commerce in the East. The expressed oil is as clear and sweet as that from almonds, and probably the Behens oil used in varnish, is no other. It is called by the Arabs "Siriteth," and the seed, "bennie" seed, in Africa.

S. orientale is grown in the *West Indies* under the name of "wanglo." It is said to have been first brought to Jamaica by the Jews as an article of food. 1,050 bags of gingelly, *til*, or sesame seed, were imported into Liverpool, in 1849, from the East, South America, and Africa, for expressing oil and 3,700 bags in 1850. There are two kinds of seed, light and dark, and it is about the same size as mustard seed, only not round.

A hectare of land in Algeria yields 1475 kilogrammes of seed, which, estimated at 50 cents the kilogramme, amounts to 737 francs, whilst the cost of production is only 259 francs, leaving a profit of 478 francs (nearly £20). The oil obtained from this seed is inferior to good olive oil, but is better adapted for the manufacture of soap. This plant is not unlike hemp, but the stalk is cleaner and semitransparent. The flower also is so gaudy, that a field in blossom looks like a bed of florist's flowers, and its aromatic fragrance does not aid to dispel such delusion. It flourishes most upon land which is light and fertile. The fragrance of the oil is perceptibly weaker when obtained from seed produced on wet, tenacious soils. A gallon of seed seems to be the usual quantity sown upon an acre.

In *Bengal, S. orientale* is sown during February and the crop harvested at the end of May; but *S. indicum* is sown on high, dry soil, in the early part of the rains of June, and the harvest occurs in September.

About *Poonah* it is sown in June and harvested in November.

In *Nepaul* two crops are obtained annually; one is sown as a first crop in April and May, and reaped in October and November; the other as an autumn crop, after the upland rise in August and September, and reaped in November and December. In Mysore, after being cut it is stacked a week, then exposed to the sun for three days, but gathered into heaps at night; and between every two days of such drying, it is kept a day

in the heap. By this process, the pods burst and shed their seeds without thrashing. The seeds contain an abundance of oil, which might be substituted for olive oil; it is procured from them in great quantities, in Egypt, India, Kashmir, China, and Japan, where it is used both for cooking and burning. It will keep for many years and not acquire any rancid smell or taste, but in the course of a year or two becomes quite mild, so that when the warm taste of the seed, which is in the oil when first expressed, is worn off, it is used for all the purposes of salad oil. It possesses such qualities as fairly entitle it to introduction into Europe; and if divested of its mucilage, it might perhaps compete with oil of olives, at least for medicinal purposes, and could be raised in any quantity in the British Indian Presidencies. It is sufficiently free from smell to admit of being made the medium for extracting the perfume of the jasmine, the tuberose, narcissus, camomile, and of the yellow rose. The process is managed by adding one weight of flowers to three weights of oil in a bottle, which being corked is exposed to the rays of the sun for forty days, when the oil is supposed to be sufficiently impregnated for use. Gingelly oil, is used in India to adulterate oil of almonds. The flour of the seed, after the oil is expressed, is used in making cakes, and the straw serves for fuel and manure. The oil is much used in Mysore for dressing food, and as a common lamp oil. From 200 to 400 quarters under the name of Niger seed are imported annually into Liverpool for expressing oil. Three varieties of Til are extensively cultivated throughout India, for the sake of the fine oil expressed from their seeds, the white seeded variety, the parti-colored, and the black. It is from the latter that the sesamum or gingelly oil of commerce is obtained. Sesamum seed contains about 45 per cent. of oil. Good samples of the oil were shown at the Great Exhibition from Vizianagram, Ganjam, Hyderabad, Tanjore, the district of Moorshedabad, and Gwalior The gingelly seed is stated to be worth about £4 per ton in the Northern Circars.—*Simmonds' Comml. Products, page* 535. Dr. O'Shaughnessy says that the sesamum plant is universally cultivated in the East for the oil expressed from the seeds a very sweet oil (siritch, *Arab.*) which is much used as an article of diet, for frictions, and lighting. The oil-cake mixed with honey and preserved citron is esteemed an oriental luxury. The leaves of the plant are used as poultices.

Nine pounds of the seed yield two quarts of perfectly sweet oil, which will keep many years without becoming rancid; the oil made in Persia, and thence largely exported, is called *Kurit schuk.* Sesamum oil is of the sp. gr. 911, insoluble in alcohol, readily saponifies with alkalies, and combines with the oxide of lead. For all purposes of medicine and pharmacy it is when well prepared quite equal to the best olive oil.—*O'Shaughnessy, p.* 479. Both the white and dark seeded varieties are cultivated in Ajmere but do not thrive well.—*Genl. Med. Top. p.* 200. Ainslie tells us it is much used by the Natives of India, in preparing their victuals and when fresh made is by no means unpleasant, and that it is highly esteemed amongst the Japanese who cultivate the plant from which the seeds are obtained that yield it in great abundance.—*Ainslie's Mat. Med. p.* 266.

Tenasserim. The sesamum plant is largely cultivated in Tenasserim by the Karens, who bring the seeds to market and sell them to the Burmese, and they express the oil. The seeds are said to have the same property as linseed, and the oil to be a good substitute for olive oil. The natives use it in curries, and also burn it for lights.—*Mason.* Sesamum indicum, has been lately introduced into the United States where it yields about 2½ gallons of oil to the bushel: the produce being about 20 bushels to the acre. Flax seed yields a gallon to the bushel. The leaf of the plant has been found an excellent remedy in the bowel complaints of children and adults, and for this purpose put or dip three or four leaves in water which they render micilaginous, but do not impart any unpleasant taste. The negroes cultivate it for food using the parched seeds with their meats.—*Ag. Rep. for* 1854 *of Com. Patents p.* 226. See GINGELLY OIL.

(7563) SESBANIA, a genus of plants belonging to the natural order *Leguminosæ*, which is so named from theArabic name of the species which is indigenous in Egypt. The rest are found in the equinoctial parts of the world, but the most remarkable in India. The genus is characterised by having a 5-cleft or 5-toothed calyx: the standard of the corolla roundish, larger than the keel, which is obtuse, 2.edged at the base; stamens diadelphous (9 and 1), with the sheath auricled at the base; legume elongated, slender, torulose, many.seeded. The species form shrubs or herbs with abruptly pinnate leaves, many pairs of leaflets, cauline stipules lanceolate, and the petiole ending in a bristle point. Flowers axillary, racemose, usually yellow.—*Eng. Cyc.*

(7564) SESBANIA ACULEATA. *Syn.* ÆSCHYNOMENE CANNABINA, Roxb, 'Fl Ind.,' iii, p. 335, and Æ. SPINULOSA, do., p. 333; LEGUMINOSÆ).

Dhunchee, HIND.

Sesbania aculeata, herbaceous, annual, erect, sparingly branched, glabrous; stem and petioles usually sprinkled with minute cartilaginous points; leaves eight to ten times longer than broad; leaflets twenty to forty pairs, linear, obtuse, mucronate; racemes axillary, peduncled, erect, lax, often about half the length of the leaves; few-flowered; flowers pretty large (more than half an inch long), on slender pedicels;

corolla about four times the length of the calyx; legumes erect, nearly terete, sharp-pointed. The natives of Bengal familiarly employ and highly esteem a fibre which is known to them by the name of *Dhunchee*, *Dhunicha*, and *Dhunsha*. It is produced by a plant which Dr. Roxburgh thought was the same as the *Æschynomene cannabina* of Konig. This was described by Retz, and stated to be a native of the Malabar coast, and that its stems yielded a strong and useful fibre, as a substitute for Hemp. Messrs. Wight and Arnott, in their 'Flora of the India Peninsula,' consider it to be identical which *Sesbania cochinchinensis*, which they have from China. Dr. Roxburgh states that he had not found his plant in a wild state, but that, in various parts of Bengal, it was cultivated for the fibres of its bark, which form a coarse substitute for Hemp. Messrs. Wight and Arnott (l. c.) unite the plant described by Dr. Roxburgh with one which is very common in all parts of India in the rainy season, the *Sesbania aculeata* of Persoon, and which is called Juyunti in Bengal, and *dhundain* in North-West India. It springs up in rice-fields, and other wet cultivation, during the rainy season. These two varieties are thus described by Messrs. Wight and Arnott, under the name of *S. aculeata*. Dr. Roxburgh gives the following general directions for its culture. The soil is generally low and wet, and not requiring much preparation, as the plant is hardy, growing from six to ten feet, and rapid in growth. This renders it advantageous to cultivate, especially as it is considered a meliorating crop. The time of sowing is when the soil has been moistened by the first showers of April or May. About thirty pounds of seed are allowed to the acre, and less weeding is required than for *Jute*. The crop is ready to cut in September and October, though the fibre does not suffer if left standing till the seed is ripe, in November. The process of steeping and cleaning the fibre is similar to that required for *Sunn*, that is, *Crotalaria juncea*. The general produce of an acre is from one hundred to one thousand pounds of ill-cleaned fibre, the current price somewhat less than that of *Paut*, viz., *Corchorus olitorius* and *capsularis*. The expense of cultivation, including land rent, is about nine rupees. This plant, generally cultivated about Calcutta during the rains, grows to the height of from six to ten feet, the fibres are long (six to seven feet), but coarser and more harsh than those of Hemp, unless cut at a very early period. From its great strength it is well calculated for the manufacture of cordage and cables. In Bengal, the fishermen make drag-ropes to their nets of this substance, on account of its strength, and durability in water. Indeed by the Bengalese it is considered more durable in water than either *Sunn* or *Paut*. It has been observed to Dr. Royle by one gentleman well acquainted with this fibre in India, that he was at a loss to know why the Dhunchee remained so much neglected in Great Britain, as it is really a very excellent fibre for common cord and twine purposes, and certainly very much superior in strength and durability to Jute. It is also a much hardier plant than Jute; the latter, indeed, being rather an uncertain crop, for the production of the fine, long, silky fibre, so much called for in England. Another gentleman observed, that though rather wiry it was strong, and chiefly remarkable for its contraction when wetted, so much so, that it would even carry away the mainmast of a ship by mere contraction. Mr. Deneef, the Belgian farmer employed in India, presented samples of the Bengal Hemp, called *Dhuncha*, to the Agri-Horticultural Society, in November, 1840, and stated that they had been dressed after the Belgian mode. A begah, he says, will yield 173 lb. of cleaned fibre, and 92 lb. of seed. A woman can dress about 4 lb. a day. In April, 1581, Captain Thompson presented a dressed sample of the fibre of the Dhuncha of Bengal, and a piece of rope made of it. This rope, he stated, had been used in various way for nearly two years, and from various reports upon it, he thought it likely to come into extensive use. Specimens of the fibre and rope were also sent to the Exhibition of 1851, and we have already given (see FIBRES) the result of the trial made with this rope in the Arsenal of Fort William, whence it appears that a three and a half inch rope of Dhunchee broke with not less than 75 cwt., though the Government Proof, required for such rope, was only 49 cwt. The price of the Dhunchee, in the interior, has long been about R. 1 8 per maund. The following are reports upon this fibre: "The Dhunchee is very suitable for ropes, and if it will take in tar, is of considerable value. It would probably fetch from £30 to £35 a ton, and after being introduced and known, perhaps £5 more." It was also valued by others at £35 in 1853. These fibres, in fact all the fibres from the East, would be much more valuable if properly scutched; and if scutching mills were sent out, these fibres could be brought in a greatly improved state to market.—*Royle Fib. Pl. p.* 293.

(7565) SESBANIA ÆGYPTIACA, the Egyptian species, found also in India, forms a small and very elegant tree; its wood is employed in making the best charcoal for gunpowder.—*Eng. Cyc.* This species of sesbania may be seen in culture for the sake of its leaves, which the Burmese use for poultices to promote suppuration. Owing to this characteristic they call the tree, water chief.—*Mason.*

(7566) SESBANIA CANNABINA, the Dhanchi of Bengal, is not found wild. It is cultivated on account of the fibres of its bark, which are coarse, but more durable than some other substitutes of hemp, especially when exposed to wet,

and are therefore generally employed for the drag-ropes and other cordage about fishing-nets.—*Eng. Cyc.*

(7567) SETARIA, a genus of Grasses containing a few species cultivated as corn-grains in some countries. The genus is named from 'seta,' a bristle, on account of the bristly nature of the involucrum. The species are found in both the hot and temperate parts of the world. The genus nearly corresponds in character with *Panicum*, under which it is sometimes included, but it is also combined with *Pennisetum*. It is characterised by having the spikelets 2-flowered, supported by two or more bristles; the lower valve is the smallest; the lower flower is neuter or male, with the valves of the corolla coriaceous and indurated, awnless, the lower one embracing the other; petaloid scales very obtuse and subfalcate; germen emarginate; seed included within the persistent glumes. The species are found both in the hot and temperate parts of the world.

(7568) SETARIA GLAUCA. Glaucous Bristle Grass, has a panicle spiked, continuous; bristles of the involucre round, with erect teeth; outer glumella of the fruit conspicuously wavy, wrinkled transversely; lower floret triandrous with two glumellas. It is found in Hertfordshire and other parts of England. The first twospecies are found in America and India. *S. Germanica* and *S. Italica* are cultivated as articles of diet in Europe and India.—*Eng. Cyc.*

(7569) SETARIA ITALICA, ITALIAN PANICLE. Panicum Italicum. Lin.

Tennay, TAM.	Caraloo, TEL.
Kang, GUZ.	Dokhn, ARAB.

Cungnie, HINDOOIE.	Arzun, PERS.
Navanay, CAN.	Prayingoo, SANS.
Navaria, MAL.	

This grain is prized by the natives of India, who make cakes of it and also prepare it as porridge. For the purposes of pastry it is very little inferior to wheat, and when boiled with milk, forms a light and pleasant meal for invalids. This article grows in abundance in the southern parts of Europe, particularly in Portugal, where it is termed Mitho Painco.—*Ainslie, page* 220.

(7570) SETARIA: *Species.* A species of setaria, which the Karens call "horsetail grass" is scattered all over the Tenasserim Provinces.—*Mason.*

(7571) SETARIA VERTICELLATA. Bristle-Grass, has a panicle spiked, lobed below; branches whorled; bristles of the involucre rough, with reversed teeth, outer glumella of the fruit nearly even; lower floret united with one glumella. It is found in cultivated fields in England. Also in India.

(7572) SETARIA VIRIDIS, Green Bristle-Grass, has a panicle spiked, continuous; bristles of the involucre rough, with erect teeth; outer glumella of the fruit nearly even; lower floret neuter, with one glumella. This species is also British and Indian.

(7573) SETHIA INDICA. *Erythroxyleæ*, Ill. 48. Roxb. c. 88.

Semboolinja marum, Thavadarum, TAM.

When fully grown, it is still a small tree, the fruit yields an oil, and the wood is esteemed as a substitute for sandal wood.—*M.E.J.R.* This, Dr. Wight believes, is the *erythroxylon areolatum* of Ainslie, when largest it is still but a small tree, Ainsiie states that the wood is so fragrant, that it is used in Mysore as a substitute for sandal wood.—*Wight.*

(7574) SEWING. The art of *Sewing* is now practised in India chiefly by men, who are Mahomedans. They form the class of tailors (durzees), who make the dresses of their Mahomedan brethren. One is usually kept in the service of most Europeans.—*Royle Arts &c. of India, page* 505

(7575) SEYCHELLE COCOA-NUT is the fruit of one of the Palms (*Lodoicea Sechellarum*), respecting which many fabulous accounts were formerly related, such as, that it was produced at the bottom of the sea, the nuts being only found thrown up on the coasts of the Maldive Islands. They were called Coco de Maldivia, or Coco de Salomon, by the early Portuguese navigators. Many marvellous medical virtues were ascribed to these nuts by the physicians of the age, both Asiatic and European, and they were consequently sold at a high price. At present they form only objects of curiosity, and are well known under the name of Double Cocoa-Nuts. The tree yielding them was first discovered by Barré, a French officer of engineers, in 1769, then described by Sonnerat, but for the first time accurately described by Labillardiere, 'Ann. Mus.' Paris, ix. p. 140, t. 13. A very full description and illustrative plates have been given by Dr. Hooker, in the 'Botanical Magazine,' N. S., Nos. iv., v., and vi., 1827; and a paper on the subject was read at the Royal Asiatic Society by a resident of the Seychelle Islands. To the inhabitants the tree is useful for its timber, which is hard externally, and employed in building their huts and for posts; the leaves and their footstalks are used for the roof, walls, and partitions, and for many other domestic purposes. The nuts weigh from 23 to 25 pounds each, and when fresh contain a white, transparent, and jelly-like substance, which is edible. The shells are employed in making vessels and dishes of various kinds, and the entire nuts form articles of commerce, as they are esteemed in other countries both for their fabled virtues and as curiosities.—*Eng. Cyc.* See LODOICEA, also SEA-COCOANUT.

(7576) SHADDOCK. A large species of Citrus, commonly cultivated in the East and West Indies, for the sake of the delicate, subacid,

juicy pulp, with which they abound. When at their greatest size, they are called Pompoleons; the smallest, form the forbidden fruit of the English markets —*Faulkner.*

(7577) SHAGREEN.

Chagrin. Fr. | Schagrim, Rus.
Schagrin, Ger. |

A sort of hard grained leather, prepared in a peculiar manner from the skin of horses and other animals, and employed in the manufacture of small cases and boxes. The leather is prepared in Poland, Astracan in Russia, and various parts of the Levant.—*Faulkner. Shagreen* differs from leather in not being tanned or tawed. It bears some resemblance to parchment, but the grain or hair side is granulated or covered with small round rough specks. It is an oriental manufacture, and the method of preparing it was long kept secret. It is said to be prepared from the skins of horses, wild asses and camels, those portions being preferred which cover the chine. The fillets of skin are steeped in water until the hair is sufficiently loosened to be scraped off; the skins are then stretched upon a board, and are unhaired and fleshed with a knife. Each fillet is then stretched in a frame, as in the preparation of parchment, and is moistened from time to time and gradually distended. While still moist, the grain or hair side is sprinkled over with the seeds of a kind of *Chenopodium*; they are hard, of a shining black colour, and about the size of poppy seed. These seeds are forced into the surface of the skin by the pressure of the feet or by means of a simple press, a piece of felt or thick stuff being laid over the seeds. In this state the skin is left to dry in the shade, and when the seeds are shaken out by beating the skin, the surface of the latter is pitted with small hollows corresponding with the forms of the seeds. The skin is now stretched on an inclined plane, by attaching its upper end to hooks and fastening weights to its lower end, it is thinned off with a half-moon knife, care being taken not to cut so far as the bottom of the little pits occasioned by the seeds. On macerating the skins in water they swell, and they become prominent over the shaven surface. The process is completed by steeping the strips in a warm solution of soda; salt brine is then used, and the skins are ready for the dyer.—*Tomlinson.*

(7578) SHALE, a term applied to any argillaceous deposit naturally divisible into laminæ parallel to the plane of deposition. Thus there are *sandy, calcareous*, purely *argillaceous*, and *carbonaceous* shales; there is also a *black* and a *brown bituminous* shale;.—*Tomlinson. Shales or fire Clays*, occur at Streepermatoor, Tripasoor, Chingleput, Mettapollium, and Cuddapah.

(7579) SHALLOT. Allium Ascalonicum. Gundhund, Hind.

Propagated in the same way as the chive.—*Riddell.* Shallots are the mildest of the onion tribe, seeds seldom; propagated by the young bulbs, used in sauces, salads, &c.—*Jaffrey.*

(7580) SHA-NEE, a bast of Arracan, of a reddish brown colour, rough and coarse.

(7581) SHARK'S FINS.

Soora meen sepputtay, Tam. | Iyu or Yu, Malay
Paak, Duk. Guz. and Hind. | and Javanese.

Sharks are numerous, and of great size in the seas of the Eastern Archipelago, and their fins are a regular article of trade for the market of China, where they are prized for their real or imaginary stimulating and restorative qualities. The name for the shark in Malay and Javanese is Iyu, or, abbreviated, Yu, and this name has a very extensive currency, for it is even found in some dialects of the islands of the Pacific.—*Crawfurd Dict. page* 378.

Sharks fins are largely exported from Bombay and Madras to China, where they are much esteemed as a strengthening food. They are chiefly collected in the Persian and Arabian Gulfs, on the Coasts of Mekran and Malabar, and other places along the sea coasts.—*Faulkner.*

The Chinese fishmongers of the Straits Settlements, also, obtain Shark's fins from the same localities which supply them with Fish maws. These fins are not exclusively selected from Sharks (Squali,) but equally from (Raiæ). Quantities examined at Pinang were composed of Fins of the following Genera: *Stegostoma, Carcharias, Sphyrna, Pristis, Rhinobatus, Trygon, and Myliobatis.* Of all fishes Sharks and Rays are the most valuable to the Chinese. The flesh and entrails of all, not even the electric Rays (*Torpedinideæ*) excepted, are eaten either fresh or dried, the skin is used for polishing or converted into Shagreen; gelatine is obtained from the larger fins, glue from the smaller. All, except the caudal fins, are cut at the root so as to leave as little flesh as possible. The root is dipped in wetted lime (Chunam) in the erroneous belief of preventing attacks of insects, and then the fins are dried in the sun. Those imported in the Straits Settlements are packed promiscuously in gunny bags, each containing from one half to one Pikul. According to the value in the Chinese market, the fishmongers assort the fins in two kinds, "white" and "black" The *white* consist exclusively of the dorsal fins, which are on both sides of a uniform light colour and reputed to yield more gelatine than the other fins. In China, the lovers of gelatinous soups pay from 30 to 40 Spanish Dollars per Pikul of white fins. The pectoral, ventral and anal fins pass under the denomination of *black* fins. The colour, however, varies according to the species from buff to grey or brown, and most of them are of two different colours, the upper surface being dark, the lower light. The black fins, for obvious reasons the most numerous, are supposed to yield a comparatively small quantity of gelatine and

sell in China from 15 to 20 Spanish Dollars per Pikul. Mr. W. T. Lewis has communicated the annexed table, shewing the quantity of Shark's fins imported into, and exported during 10 years from Penang to China. The total quantities of Shark's Fins imported into and exported from Prince of Wales Island, from 1832 to 1842, were

Cantor.

Shark's fins are sought for from the Indian ocean to the Sandwich islands to supply the Chinese market. The chief supply is from Bombay and the Persian Gulf. They are fat, cartilaginous, and when cooked, esteemed by the Chinese as a stimulant and tonic. They should be thoroughly dried and kept from any moisture. About five hundred pieces are contained in a pecul. The price is from $6 to $60 per pecul. There seems to be little or no choice as to what species of shark the fins are from, but those of a whitish color are valued much higher than the black sort. Sharks and rays of all kinds form a common article of food on the Chinese sea coast. The trade in shark's fins is likely to extend at the north —*Morrison.* Travancore sends Shark's Fins which is a favorite article of diet with the Chinese, and is largely exported.—*M. E. J. R.*

(7582) SHA-PHYOO, a bast of Arracan, long, thin, smooth layers, light-colored, tough and flexible.

(7583) SHAWLS.

Chals, Chales, Fr.	Shawl, Pers.
Schalen, Ger.	Chales, Port.
Shawl, Guz. Hind.	Schavalos, Sp.
Shavali, Ir.	

Are well-known articles of dress, made of wool, silk, or more commonly of silk and wool mixed. The finest shawls are those made at Cashmere, which are largely exported from Bombay to London. The chief seats of the shawl manufacture in Britain are, Paisley and Norwich; the French shawls are, however, much more esteemed than the English.—*Faulkner.*

Although in many branches of textile manufacture, England has outstripped her oriental teacher, we still find among the workmen of the East, a degree of taste in the adjustment of their designs, an amount of skill applied to the getting-up of the fabric and the blending of patterns and colours so aptly combined, as to leave nothing to be desired, but rather to shew that what we are now arriving at in arts-design by the aid of scientific teachings, has been practised amongst that ancient race during the last thousand years. The correct principle which science has laid down in the schools of the West, that the patterns and colours of woven goods should diversify plain surfaces without disturbing the impression of flatness, has evidently been known to them from the earliest times. Nor is it in this alone that the workmen of the East excel: they are equally celebrated for the rich and varied beauty of their patterns, and the strict appropriateness of these to the colours employed. Foremost amongst the woven fabrics of India are the world-famed shawls of Cashmere, the finest of which, in spite of many imitations in Europe, are still produced in the "Vale of Cashmere," whence continues to come the supply of the most valuable wool employed in the manufacture. The Cashmere goat thrives no where so well as amidst the grassy ravines and shady clefts of the Cashmerian hills; and from the neck and under part of the body of the animal is taken the fine, flossy, silk-like hair, which is worked up into these beautiful shawls with an exquisite taste and skill which all the mechanical ingenuity of Europe has never been able to imitate with more than partial success. Mention may be found of these shawls in the *Mahabharat* and other ancient works of the East. The people of the countries adjacent to Cashmere are there spoken of as bringing skins and cloths of wool embroidered with gold as tribute to the sovereign. From the *Ayeen Akberry*, written in the sixteenth century, we gather that the Emperor Akbar encouraged the manufacture of these shawls by every means in his power, even designing some himself, and introducing a greater and richer variety of colours in their patterns. The same work informs us of the extension of this manufacture to the state of Lahore, where it is said there were then a thousand manufactories employed on them. A mixture of wool and silk for turbans is also spoken of; and some space is occupied with an enumeration of the various qualities of the shawls and turbans, and the mode of classifying them for value. Since the above period, the many troubles and political changes in the position of country have materially affected this branch of industry; and we accordingly find that from 30,000 looms, which was at one time the number at work in Lahore, there were, some years since, but 16,000. Doubtless the more settled state of the country, and the increasing demand for the article in various parts of the world, will now help to revive this manufacture. In all eastern countries the shawl is ever considered the most essential and graceful part of ornamental dress; and even in Europe, with their many beautiful imitations, the true Cashmere shawl is still sought and paid for at enormous prices. Even in India it is by no means unusual for a rajah to pay ten thousand rupees (1000*l.*) for one of the finest of those productions; and which, in all probability, will have cost the labour of a whole family for a

life-time. The annual value of these shawls imported into Great Britain does not exceed six or seven thousand pounds, and forms no sort of criterion as to the yearly produce of the Cashmerian looms, since by far the most valuable are taken by native kings and rajahs, and large quantities are also dispatched to Russia, Turkey, Greece, America, and continental Europe. Previous to the imitation of these goods at Paisley, the imports had amounted to as much as 16,000*l.* annually. In embroidered shawls, scarfs, handkerchiefs, &c., in silk, cotton, and mixed fabrics, India stands preemenent. Here also as in the make of Cashmere shawls, the Hindoos, by their skilful and delicate manipulation, are able to produce fabrics of such exquisite fineness, as to defy the more scientific labours of European nations. Their scarfs of brocaded gold and silver, laid upon red, white, and green grounds, and worked in and interspersed with beetle's wings, and other ornaments, are at once the wonder and admiration of the world.—*Capper's Three Presidencies.*

Bangalore Silk Shawls. At the Madras Exhibition of 1855, two Bangalore *Silk Bed Quilts* exhibited by Moonshee Nunjapah (CLXXIV 147) Dondala Esmursan (CLXXIV 158) were good specimens of this description of native manufacture, and the jury would have assigned a prize to the first as being the superior article of the two, had not both been priced so much above their real value as to prevent their being brought into general use.

A Bangalore Silk Shawl by Moonshee Nunjapah (CLXXIV 153) weighing 2 lbs. 3 oz. 5⅔ dr. price 125 Rs. was the best woven fabric of this description, and the jury awarded him a 2nd Class Medal.

(7584) SHAWL WOOL GOATS. In Thibet, there are two varieties; one is a large animal, with great horns, called Rappoo; the other smaller, and with slender horns, is called "Tilloo." The latter yields the finest wool, but they are mixed for ordinary purposes. Dr Hooker was assured that the sheep, of which large flocks were grazing near, afford the finest wool of any. The animals were caught by the tail, their legs tied, the long winter's hair pulled out, and the remainder cut away with a broad flat knife, which was sharpened with a scythe stone. The operation was clumsily performed, and the skin much cut.—*Hooker, Him. Jour. Vol.* II. *page* 88.

(7585) SHELL, The protective covering of a class of animals widely distributed throughout the earth, the fresh water, and the ocean. This covering is in most cases exterior, and large enough to enclose the whole body; but in some cases it is interior, and only of sufficient size to protect the heart and lungs. Shell is a secretion from the skin which covers the back of the animal, and which is of a peculiar thickness and fleshy consistence, and is called the *mantle.* This fleshy mantle is very evident on the back of the common grey slug, in which it covers only a portion of the body, and contains in general, within the substance, an internal shell, small, flat, transparent, and oval. The snail affords a familiar instance of an external shell. Shells are called *univalve* or *bivalve* according as they consist of one part, or of two parts joined together by a hinge. The snail is univalve, the oyster is bivalve. Bivalves are inferior in the scale of existence to univalves, both as it respects powers of motion and organs of sense. The generality of the bivalve shells, including various oysters, muscles, &c., are termed *nacreous* shells, from *nacre*, the French for mother-of-pearl. Their structure and uses in the arts have been already treated of Molluscous animals were chiefly represented in the Exhibition of 1851, by the ingenious arrangement of their shelly coverings in the form of vases, baskets, &c. An elegant epergne was exhibited, composed entirely of shells gathered from the shores of the Bahamas, arranged as cornucopias filled with flowers, in great variety of colour and beauty. Also a large vase from the same islands with a group of flowers composed entirely of pure white shells. Shell bracelets from Dacca, with a half moon saw, and complete set of apparatus used by the bracelet-makers, were curious. There were also interesting specimens of the conchology of Jersey, among which was the *Oreille de Mer*, a shell-fish abundantly found in that island, and used in a variety of ways for food, while the shell is preserved, and exported to England, where its pearly iridescence causes it to be valued in ornamental papier mache works. There were also vases and table-tops, from the Channel Islands, richly ornamented with wreaths of shells. The little island of Herm affords an immense collection of interesting shells, in which the greater part of the devices were executed. Bouquets in shell-work from the Mauritius, specimens from the Eastern Archipelago, and leaves, baskets and flowers, in the same material, from France, completed the large amount of shell-work displayed in the Exhibition. The so-called *Shell* of the tortoise, which is merely a bony covering, and different in structure from true shell, was displayed in its natural state, and in a variety of beautiful fancy articles, from Ceylon, the Eastern Archipelago, France, Trinidad, &c. The beautiful lining of oyster-shells, known as mother-of-pearl, was manufactured into articles of great beauty, while a profuse display of the pearls themselves, the produce of the pearl-oyster, or rather mussel, were very interesting to look upon, though they are, in fact, a proof of disease in the animal which secretes them. Pearls are produced when the transparent envelope of the animal, called the mantle, is wounded or irritated. There are small, boring worms, which pierce the shell

and penetrate to the body of the animal. The mantle then sends forth a quantity of pearly matter over the wounded spot, and this becomes a little knob or pearl. Grains of sand, or other minute substances entering the shell, are in the same way coated over with pearly matter. *Tomlinson*, p. cxxix. It remains therefore to speak of the univalve shells, and their employment in the arts. Most of the univalve shells are of the character called *porcelanous* from their brittleness, translucence, and the resemblance of their fracture to that of porcelain. But this fracture when examined by the miscroscope reveals a structure of thick parallel layers, usually of a finely fibrous nature, at right angles to the external surface. Dr. Aikin says that these fibres are often nothing more than the transverse section of thin transparent parallel lamellæ, which when viewed on their broad surfaces often exhibit the usual natural joints of calcareous spar. The soluble part of these shells is carbonate of lime, the particles of which are cemented together with a very minute proportion of animal mucus. The hard and compact nature of such shells, and their generally smooth surface, prevent their being cut by the ordinary tools, which are available for the less hard and frangible nacreous shells: it is therefore necessary to treat them after the manner of the lapidary, with emery, rottenstone, and other substances harder than the shells themselves. Such shells generally require rather to be polished than cut, but where it is necessary to divide them in order to exhibit their sections, they are operated upon by means of the slicer with diamond powder. Certain descriptions of these shells are well adapted for cameo-cutting, on account of their substance being made up of differently coloured layers, and also on account of a difference of hardness and texture in the different layers, some approaching more nearly to the nature of nacreous than of porcelanous material. Specimens of cameo-shells, and of the rude but efficient instruments for cutting them, were shown in the Indian collection of the Great Exhibition. The shells were dense, thick, and consisted of three layers of differently coloured shell material. "In the *Cassia rufa* each layer is composed of many very thin plates, in other words is laminated, the laminæ, being perpendicular to the plane of the main layer: each lamina consists of a series of elongated prismatic cells, adherent by their long sides. The laminæ of the outer and inner layers are parallel to the lines of growth, while those of the middle layer are at right angles to them." Several varieties of the genus *Strombus* or conch, supply suitable shells for cameo cutting. The outer layer is nearly colourless, can be operated upon with steel tools, and may be carved into smooth and finished forms. Experience has taught the cameo-cutter to choose the kinds known as the *Bull's Mouth*, the *Black Helmet*, the *Horned Helmet*, and the *Queen Conch*, of which the first two are the best. The art of cameo cutting was confined to Rome for upwards of forty years, and to Italy until the last twenty-six years, at which time an Italian began cutting cameos in Paris, and now upwards of 300 persons are employed in the trade in that city. About thirty years ago, the total annual number of shells used in the trade was about 300: the whole of them were sent from England, and they were worth 30 shillings each in Rome. But so rapid was the progress of the manufacture when it became more widely diffused, that the following numbers were given a few years ago, (1847,) by Mr. Gray, as the consumption of shells in France for this purpose.

Bull's Mouth	80,000	average price 1*s.* 8*d.*	value 6,400*l.*
Black Helmet	8,000	5*s.* 0*d.*	1,800*l.*
Horned Helmet	500	2*s.* 6*d.*	60*l.*
Queen Conch	12,000	1*s.* 2½*d.*	700*l.*
	100,500 shells.		£8,960

The average value of the large cameos made in Paris, as stated by the same authority, is 6 francs each, giving a sterling value of 32,000*l.*, and the value of the small cameos is about 8,000*l.*, giving a total value of the cameos produced in Paris, in one year, (1846,) at 40,000l.; while at the same time in England, not more than six persons were employed at the trade. The Black Helmet, on account of the advantageous contrast of colour in the layers, produces very effective cameos, the carved figure of the white upper layer being strongly relieved by the dark, almost black ground, supplied by the second layer. The shell is first cut into pieces the size of the required cameos, by means of diamond dust and the slitting mill, or by a blade of iron or steel fed with emery and water. It is then carefully shaped into a square, oval or other shape on the grindstone, and the edges are finished with oilstone. It is next cemented to a block of wood, which serves as a handle to be grasped by the artist while tracing out with a pencil the figure to be cut on the shell. The pencil mark is followed by a sharp point, which scratches the desired outline, and this again by delicate tools of steel wire flattened at the end and hardened, and by files and gravers, for the removal of the superfluous portions of the white enamel. A common darning-needle, fixed in a wooden handle, forms a useful tool in this very minute and delicate species of carving. The careful manipulation necessary in this work can only be acquired by experience, but there are general rules thus sensibly given which the learner would do well to remember:—"As in all other processes of producing form by reduction, the general shape should be first wrought, with care to leave every projection rather in excess, to be gradually reduced as the details and finish of the work are approached. To render the high parts more distinct during the process of carving, it

will be found convenient to mark them slightly with black-lead pencil. Throughout the cutting, great caution should be observed, that in removing the white thickness the dark ground is not damaged, as the natural surface of the dark layer is far superior to any that can be given artificially; indeed, should the ground be broken up at one part, it would be requisite from its lamellar structure to remove the entire scale or lamina from the whole surface, a process that will be found very tedious, and much more difficult than the separation of the white from the black thickness. In order that the finished cameo may possess a distinct outline at all points of view, it is desirable to adopt the system followed in antique cameos, namely to leave all the edges of the figure quite square from the ground, and not gradually rounded down to the dark surface; should this latter method be followed, it will be found that the outline is in many place undefined owing to the colour of the white raised figure of the cameo gradually emerging into that of the dark ground: this evil is entirely avoided by leaving the edge of the figure quite square, for the thickness of about $\frac{1}{50}$th of an inch. The surface of the cameo should be finished as nearly as possible with the cutting tools, as all polishing with abrasive powders is liable to remove the sharp angles of the figures, and deteriorate the cameo by leaving the form undefined. When, however, the work has been finished as smooth as possible with the cutting tools, the final polish may be given by a little putty-powder used dry, upon a moderately stiff tooth-brush, applied with care, and rather to the dark ground than to the carved surface; this is the concluding process, after which the cameo is ready for removing from the black prior to mounting." The covering of the tortoise does not properly come under the denomination *shell*, partaking as it does of the nature of *horn*.—*Tomlinson*. *Shell* then is the hard calcareous substance, which protects either partially or entirely the Testaceous Molluscs externally, or supports certain of them internally. This substance, when external, may be considered as the exo-skeleton of the animal; when internal, as its endo-skeleton. What is called the Nacre in shell, and which is more especially observed in their interior, and which is distinguished by the iridescence produced by the action of light, is found to consist of layers or folds of membranous shell-substance. When examined under the microscope, this substance exhibits a series of layers, and it has been supposed that these are alternately layers of membranous and calcareous matter; but Dr. Carpenter has shown that when these layers are decalcified they exhibit the iridescence, but that when the corrugations are removed by stretching, the membrane no longer exhibits its beautiful hues. The Pearls found in the interior of the shell of many species of *Mollusca* seem to result from the deposit of the nacreous substance around some nucleus mostly of foreign origin. They are probably always formed between the mantle and the shell, although sometimes found in the muscles or viscera of the animal. The *Avicula margaritifera* is called the Pearl Oyster, on account of the frequency with which pearls are found in its interior. Pearls are not unfrequently found in the common oyster, and most fishmongers possess specimens which they have obtained from oysters they have opened. Many of the fresh-water *Conchifera* of European rivers contain them. The *Unio margaritiferus* yields them. It is said that the reputation of British pearls excited the cupidity of Julius Cæsar, and that he presented a buckler covered with them to Venus Genetrix, which was suspended in her temple. Pliny speaks of British pearls disparagingly. Those obtained from the *Unio* are generally very good; but many are procured from the *Mytilus edulis*, and these are not so valuable.(Forbes and Hanely, 'British Mollusca.') —*Eng. Cyc.*

(7586) SHELLAC.

Chapta-Lac, Duk. Guz. & Hind.

The most common form in which lac is generally known, is the substance liquified, strained, and formed into thin transparent laminæ.—*Faulkner*. See Lac.

(7587) SHERBET. A favourite, cooling, and refreshing beverage used in the East; and made of the juice of limes, pomegranates, pine-apples, and other fruit, mixed with water aud sugar, with the addition of rose-water, or some other fragrant ingredient. The Persian sherbets are most esteemed.—*Faulkner*.

(7588) SHERRY. A well known wine, of a deep or light amber colour. When good, it has a fine aromatic odour; its taste is warm, with some degree of the agreeable bitterness of the peach kernel. It is principally produced in the vicinity of Xeres in Spain. It is extensively used as a dinner wine.—*Faulkner*.

(7589) SHIELDS.

Daraq, Arabic.	——, Tel.
Dhal Hind.	Siphar, Pers.
——, Tam.	

The use of the *Shield* or *Buckler* seems to have been universal over the Malay and Philippine Archipelagos before the introduction of fire-arms, and is still continued by all the ruder tribes. In Malay there are no fewer than seven different names for it, four of which are native, —two taken from the Javanese, and one from the Telugu. These names, however, refer to the different forms of it, rather than constitute synonyms.—*Crawfurd Dict. p.* 379

(7590) SHIMBEAMS, in Madras, are planks 20-to 30 feet long; ½-to 2-feet in breadth, and from 4-to 8-inches thick.

(7591) SHOES.

Schoenen, Dut,	Baschmaki, Rus.
Soulies, Fr.	Zapatos, Sp.
Schuhe, Ger.	Cheroopoo also
Joora, Guz.	chupatoo, Tam.
Jootie, Hind.	Chuppoo, Tel.

Are articles of covering for the feet, generally made of leather, and too well-known to need any description.—*Faulkner.* The Shoes, or rather slippers worn by the natives of Southern India, are generally of red leather if for men: they are made for the Madras market at Trichinopoly or Arcot, the patterns are called Appashahee; Chanddooroo; Chuppul; and Nok-dar: The rich natives use a buff coloured cloth. The slippers of females are ornamented with spangles. Their price is from 4 annas to a rupee.—*Herklots.* Thunberg says the shoes of Japan are always the shabbiest part of the dress of the Japanese. As they are of straw, they consequently last but a little time. But they are made in immense numbers, cost but a trifle, and may be bought in every town and village in the Empire. The pedestrian, therefore, throws away the old pair by the road side, and buys new ones as he goes along; while the more provident man takes two or three pairs with him on starting. Immense numbers of those discarded shoes may be found on the sides of all the roads. In wet weather they wear under the shoe a wooden clog, which is attached to the foot by ties of plaited straw. Dignitaries sometimes wear slippers made of fine rattan slips neatly plaited.—*American Expedition to Japan*, p. 65.

(7592) SHOLA OR SOLA. This root is made into toys, artificial flowers, birds, garlands, floats for nets, or for bundles for crossing rivers. When charred it answers for tinder.

(7593) SHOREA, a small Indian genus of Plants, belonging to the natural order *Dipterocarpaceæ*, named in compliment to Sir J. Shore, afterwards Lord Teignmouth, then Governor-General of India. The genus is found as far south as the line; and *S. robusta*, the best known and most useful species, as far north as 30 N. lat in many parts forming the forest which skirt the south-western base of the Himalaya Mountains. The genus is characterised by having a calyx of 5 sepals enlarging into 5 long wings; petals 5; stamens 25 to 30; fruit 1-celled, 3 valved, and 1-seeded. The family to which the *Shorea* belongs is remarkable for the number of useful products yielded by its different species, as the camphor of Sumatra, resin, wood-oil, and valuable timber. *S. robusta* is remarkable on all these accounts, as it is a lofty and ornamental tree with showy inflorescence. It is well known as a timber-tree by the name of 'Saul,' or 'Sal', and chiefly employed in the northwestern province of India in all government works, house-timbers, gun-carriages, &c. The wood is of a uniform light-brown colour, close grained and strong. The tree exudes a resin which by the natives is called 'rál', and by the Europeans one of the kinds of Dammer, being used for the same purposes as any other resins, and in Bengal very frequently as a substitute for pitch in the dockyards. It is also sometimes used by the Hindoos as an incense.—*Eng. Cyc.*

(7594) SHOREA: *Species.* Doubtful Shorea. The largest tree in the Tenasserim Provinces of the wood oil tree family, yields no oil, and is probably a species of shorea; but, says Mr. Mason, have never seen it either in flower or fruit. It is principally used for making large boats, but its places of growth are usually of difficult access by water, and it is not in very general use. Mr. O'Riley says: "It is well adapted for spars for vessels."—*Mason.*

(7595) SHOREA ROBUSTA, Saul Tree. Roxb.

Uswukunida, Sans.	Saj, Arab.
Eing-gyeen, Burm.	Saul, Hind.

Shorea robusta or Saul tree, is of great size, a native of Morung, the Paulghaut mountains &c. Sepals afterwards changing into 5 long wings, petals 5, stamens 15, filaments capillary below the anthers, anther cells short, obtuse, connectum filiform, produce beyond the cells into a more or less elongated colored, deciduous bristle, ovarium 3 celled, with two pendulous ovules in each cell. Seed solitary, cotyledons stalked, not crumbled, radicle superior, leaves coriaceous, oblong, obtuse, often emarginate at the base, panicles numerous from the axils of the fallen leaves, branches and pedicles glabrous. The *Shorea robusta*, and indeed some other species, yield abundance of the resin called dammer, the superior kinds of which are efficient substitutes for the pine resin of the European Pharmacopœiæ. Captain Jenkins of Assam forwarded specimens of resin perfectly transparent and colorless; in the bazars the color ranges from pale amber to dark brown. It is devoid of taste and smell. Sp. gr. 1·097 to 1·123, easily fusible, partially soluble in alcohol (83 1 per 1000) almost entirely in either, perfectly in oil of turpentine and the fixed oils; sulphuric acid dissolves and gives it a red color. Two parts of colorless dammer and 2½ parts of oil of turpentine, make the best varnish for lithographic drawings. The dammer of the Northern Circars is chiefly produced by the varieties of the genus Shorea. The *Shoreas* are also found growing to a very limited extent on the Western coast, but do not appear to produce much, if indeed any. of the resin collected for sale. Saul is the Hindoostanie name of the very valuable wood of this tree, and is commonly employed for the beams and inside planks of ships.—*Ains. Mat. Med. p.* 210. Sal grows in a thick forest on Paras nath, in Behar.—*Hooker, page* 21. The Burman books say that Gaudama died in a grove of engyen trees; and the Pali name of en-

gyen is *thala*, the Sanscrit sal, the name of the *Shorea robusta*. It not improbably exists in the Tenasserim Provinces, but the trees of the dipterocarpus tribe are so large that, to use the language of Griffith, "the flowers are frequently inaccessible." On one of the islands near Mergui, Mason found an enormous tree, whose dry fruit, with the calyx enlarged into five long wings, proved that it was at least a species of shorea, and on the Karen mountains he gathered a similar fruit. The natives say that a part of the petrified wood found in the valley of the Irrawaddy belongs to this tree, and the Burman books that Gaudama was born under one of them; although the savans state that he was born under a Jonesia. *Shorea robusta* according to Captain Munro "is probably the best timber tree in India," and every species of the natural family that produces it, affords valuable timber.—*Mason.* In Pegu, *Shorea robusta* is found chiefly on the Shan side of the Tounghoo district, and in the Forests north of Tounghoo.—(McClelland's Light-brown wood) Dammer unites with the oxide of lead and forms plasters. Two parts of colourless dammer and 2½ of oil of turpentine make the best varnish for lithographic drawings —*O'Shaughnessy, page.* 221. The dammer that exudes from the cuts in the trunk of the black dammer tree (Canarium) of the Malabar coast, seems to be a great favourite of several species of insects especially of one resembling a bee, called by the Hillmen "Kulliada" (*earth hole*) which live in pairs in holes in the ground. This curious circumstance will doubtless account for the mode of formation of the resin called in Burmah, Poon-yet and Poey ne-yet specimens of which were exhibited at the Madras Exhibition of 1857, and are said to be found in the ground and supposed to be produced by some hymenopterous insect, it is also found in hollow trees. This substance although composed chiefly of a yellow brittle resin mixed with more or less sand or earth has an appearance precisely like that which would be looked for if used by an hymenopterous insect in the construction of its cells (See classified Catalogue of the Madras Exhibition of 1857, Class iv.) The Madras Exhibition of 1855, contained a substance from Malacca called "*Dammer klootee*" which had been evidently formed in the same manner, although the cells were longer and the resin black and harder than the Poon yet. Specimens of this curious substance *Poon-yet*, were exhibited by Dr. Cleghorn and the Honorable W. Elliot, Esq. They were brought from Burmah and are said to be produced by a species of Hymenopterous insect in holes in the ground and hollow trees. Indeed the cellular structure of the specimens much resemble that of a wasp's nest. In the course of the Jury's investigations of the origin of the dammers of the western coast, it was incidentally mentioned that a species of bee appeared exceedingly fond of the liquid dammer of the Canarium, this insect lives in holes in the ground and it will probably be found on inspection that its cells are composed of a similar substance to that now under consideration. —*M.E.J.R. of* 1857. Pwai-ngyet, *Burmese*, is given by Dr. McClelland as the Burmese name of the Resin of this Shorea.—*McClelland, p.* 141.

(7596) SHOREA (VATICA,) *Species.* LARD SHOREA. On the mountains in the interior of Tenasserim is a species of shorea which produces an oil of the consistence of lard, and has been hence named by the Karens "the hog's lard tree." The books say that the shoreas produce resin, and dipterocarpus oil, but the fine long scarious wings of the dried calyx afford incontrovertible evidence that it is a species of shorea.—*Mason.*

(7597) SHRUB ('Frutex'). All plants are divided into herbs, shrubs, and trees. A shrub is a plant with a woody stem, which approaches the tree in its duration and consistence, but never attains the height of a tree, and is generally taller than the herb. It varies in height from about four to twelve feet. Linnæus attempted to distinguish trees from shrubs by the former having buds and the latter having none. But this distinction is of no avail, as plants like the willow, generally called shrubs, passes buds, whilst most trees in hot countries are without them. In horticulture, shrubs are two well known to need a definition. For practical purposes they are divided into the deciduous and evergreen kinds, and each of these kinds may be further divided according to their hardy or tender habits, their form, size, mode of growth, colour, &c. The most ornamental flowering shrubs are those belonging to the genera *Rosa*, *Rhododendron*, *Azalea*, *Kalmia*, *Andromeda*, *Vaccinium*, &c. Among the evergreen shurbs are the Holly, the Ivy, the Jasmine, the Box, various Heaths, &c. Shrubs are often planted together, forming what are called shrubberries, and when the kinds are judiciously selected and arranged, these collections add greatly to the beauty of the gardens and pleasure-ground where they are introduced.—*Eng. Cyc.*

At the Madras Exhibition of 1855, a few shells were exhibited, belonging to the genera, *Haliotis*, *turbo*, &c., useful in connection with the manufacture of mother of pearl buttons, likewise the *Chanks*, which the Hindoos use in their processions, the exportation of these is very great, chiefly to Calcutta.—*M. E. J. R.* The inland waters of China produce many species of shells, and the new genus Theliderma allied to the Unio, was formed by Mr. Benson of Calcutta, from specimens obtained of a shopkeeper at Canton. The land shells are abundant especially various kinds of snails, and are not altogether unknown as articles of food. A catalogue of nearly sixty shells obtained in Canton, is given in Murray's China (v. iii p. 445), but it is doubtful whether more than a majority of them

are found in the country as the shops at Canton are supplied in a great degree from the Indian Archipelago. Shells are common along the coast; Dr. Cantor mentions eighty-eight genera occurring between Canton and Chusan.—*Williams, page* 272.

(7598)SHULGUM. BRASSICA RAPA. Turnip.

(7599) SHUMAC OR SUMACH. Sometimes called young fustic, is the powder of the leaves, peduncles, and young branches of a small deciduous plant (Rhus coriaria) native of the South of Europe, but which is also grown in Syria and Palestine, for its powerful astringent properties, which renders it valuable for tanning light colored leather, and it imparts a beautiful bright yellow dye to cottons, which is rendered permanent by proper mordants. It is principally imported from the Ionian Islands and the Morea. The species grown for the purpose in Spain, Portugal, and Italy is R. Cotinus, a shrub with pale purple flowers, whereas R. Coriaria has greenish yellow blossoms. They may be propagated by cuttings of the roots and layers. R. typhina and R. Glabra with their varieties, are North American species, which are also used for tanning purposes. In Montpellier and the South of France the twigs and leaves are known under the name of redoul or roudo. They are gathered every year, and the shoots are chipped or reduced to powder by a mill. The imports into the United Kingdom were in 1846, 10,256 tons; in 1847, 11,975 tons; in 1848, 9,617 tons; in 1849, 12,590 tons; in 1850, 12,929 tons and in 1852, 9,758; which were all retained for consumption. In 1841, we received about 9,000 tons from the port of Leghorn. There were exported from Sicily in 1842, 123,305 tons, valued at £68,894. It is imported in packages of about a cwt., wrapped in cloth. America takes a large quantity of Sumach. The imports into the port of Boston alone, were 19,070 bags in 1847, 34,524 in 1848 and 30,050 in 1849. The prices in Liverpool duty paid in the close of this year, are per cwt.

Simmonds.

The trees producing Shumac, are,

Rhus Coriaria, Hide or Elm-Leaved Sumach.

Shumuk, PERS. | Tumtum, ARAB.

A native of Persia, Syria, Palestine, and the south of Europe, about 8 or 10 feet high, divided into numerous irregular branches. All parts of this plant are inodorous, but have a styptic taste; to the abundance of tannic acid it owes its properties and value in the arts: M. Tromsdorf has found in the berries a large quantity of bi-malate of lime.—O' *Shaughnessy, page* 282. Leaf 5-7 pairs of villous leaflets, elliptical, bluntly and coarsely toothed, petioles naked. Flowers in large loose panicles of a whitish-green. Drupes villous. This plant is extensively used for the purpose of tanning, and it is said that all the leather made in Turkey is tanned with the bark of this species of *Rhus.* The fruit is acid and astringent, and the seeds are often used as tonic for exciting the appetite.

Rhus continus, Venus-Sumach, or Wild Olive. Flowers hermaphrodite, arranged in loose panicles of a greenish-yellow colour: leaves simple, entire. This a very ornamental shrub, and is one of the European species, growing wild in various districts of the south of Europe. It is made use of, like many other of the species, for tanning, in Italy, and is called Scotino. The wood is used by the modern Greeks for dyeing wool, which is said to be of a beautiful rich yellow. It is frequently cultivated on account of its beauty.

Rhus glabra, Smooth Leaved Sumach. Leaf like the last, but broader and glabrous. Branches also glabrous. Fruit red, covered with silky hairs. This species, as well as another named *R. viridifolia,* is considered by some botanists as only a variety of *R typhina,* Like the last, this species is abundant in North America, over-running sometimes a whole district, and forming a troublesome weed. Its fruit is very sour, but may be eaten with impunity. Bees are very fond of the blossoms.

Rhus typhina, Fever-Rhus, or Stag's-Horn Sumach. Leaves with 8-10 pair of leaflets and an odd one, lanceolate-acuminate, serrated, pilose beneath. There are two forms of this plant; the one *R. t. arborescens,* in the form of a tree, from 10 to 25 feet in height; the other *R. t. frutescens,* shrubby, and only from 2 to 10 feet high. The young shoots are covered with down, which, with their somewhat crooked and stunted branches, give them the appearance of young stags'-horns: hence their name. The flowers are in dense spikes, at the ends of the branches, the pistilliferous ones developing themselves into woolly drupes, which are very conspicuous when ripe. It is found in every part of North America, and its dark-red leaves add much to the beauties of an American autumn. The fruit of this plant is exceedingly sour, and on this account it is frequently called vinegar plant, and is even used in some parts as a substitute for vinegar.

(7600) SIAMULIUM. A troublesome, dipterous insect (the "Peepsa," a species of *Siamulium*) swarms on the banks of the streams uniting with the little Rungeet river in Sikkim. It is very small and black, floating like a speck before the eye; its bite leaves a spot of extravastated blood under the cuticle, very irritating if not opened.—*Hooker Him Jour. Vol.* I. *p.* 157.

(7601) SIBIA GLOMERATA.

Thit-phyew, BURM.

Very plentiful in Prome, Pegu and Tounghoo,

as well as about Donabew; a compact and close-grained wood, seven or eight feet in girth, and is a timber that deserves to be attended to with a view of bringing it into use. Wood, white colored, adapted for fancy work and cabinet making.—*McClelland.*

(7602) SIDA, a genus af Plants belonging to the natural order *Malvaceæ*, containing nearly 200 species, which are very extensively distributed throughout the warm parts of the world, and abound in the peninsula and plains of India. The name was originally applied by Theophrastus to a plant growing in moist situations, which is believed to have been an *Althæa*, also belonging to the family of *Malvaceæ*, and was adopted by Linnæus for this genus.

Sida is characterised by having a naked quinquifid calyx with valvate segments, Corolla with 5 petals, which are obovate, with the claws often united into a tube, and joined to the bottom of the stamen tube. The stamens numerous, with their filaments connected into a columnar tube at their base, and free at the apex, bearing the reniform anthers. The styles are numerous, but more or less united at the base. Capsule 5-or many-celled, Cocci single-seeded; seeds suspended, roundish, and flattened. The species of this genus vary much in habit, as well as in the structure of their fruit and seeds, but they resemble each other, as indeed do all Malvaceous plants, in abounding in mucilage, and in some of them having tough ligneous fibres, which are employed for the purposes of cordage in different countries. From their mucilaginous nature several are employed as demulcents in India, such as *Sida Indica*, *S. Asiatica*, and *S. populifolia*, in the same way that the Mallow and the Marsh-Mallow are in Europe. The leaves of *S. carpinifolia* (a native of Brazil and the Canary Islands) are chewed by the Brazilians, and applied with success to the stings of wasps and bees. *S. rhomboidea* and *S. rhombifolia* abound in very delicate flax-like fibres, which may be used for many of the same purposes as hemp and flax; but when the plants are grown for the sake of their fibres, they ought to be sown thick, under which circumstances, like other plants similarly sown, they grow tall and slender without branches. So *S. periplocifolia*, a native of the Malay Islands, which succeeds well in India, may be cultivated for the same object, especially as when cut near the earth it quickly shoots into long simple twigs which abound in flax-like fibres. A species, *S. tiliæfolia*, is actually cultivated for this purpose in China. Seeds of this species were received at the Calcutta Botanic Garden under the name of King-ma from Pekin, in the neighbourhood of which the plant was said to be cultivated as a substitute for hemp and flax. At Rio Janeiro the straight shoots of *S. macrantha* are employed as rocket-sticks.—*Eng. Cyc.* Wight gives Sida acuta, 95; *Indica*, 12; and *populifolia*, 12.

(7603) SIDA ACUTA, Asiatica, indica, graveolens, &c. are malvaceous plants common in every part of India many of them containing fibres which might be turned to useful account.

(7604) SIDA HEMP OR FLAX OF BURMAH is the product of two species, Sida acuta and Sida stipulata, (Burmese, Pyen-dan-gna-len.) They are mere weeds, but the most troublesome, in Tavoy.—*Mason.*

(7605) SIDA LANCEOLATA, RETZ.

Sida acuta, BURM. | Kureta, DUK.
Pata, SANS.

A common plant, grows wild in many parts of the Deccan; flowers small, yellow, grows to the height of about three feet; and no doubt, like the S. Rhomboidea, a good fibre might be procured from it.—*Riddell* It is a native of the peniusula of India, and found also in the hilly districts. The root resembles common liquorice and is very bitter. Dr. Ainslie informs us that the infusion of this root combined with ginger is given in intermittents and in chronic diarrhœa. The leaves bruised with oil are applied externally as a poultice to accelerate suppuration. Dr. O'Shaughnessy used an infusion of the root with some advantage in the cases alluded to by Ainslie, but could not satisfy himself as to its febrifuge action. It promotes perspiration, increases the appetite, and is in many respects a useful substitute for more costly bitters. An electuary is prepared, in Bengal, from the expressed juice of the *Sida* and used in the treatment of worms in the intestinal canal, but experienced native practitioners say that no reliance can be placed on its efficacy. Care must be taken not to confound the classical name of this plant with the *Sidhee* of the bazar, which is a mixture of the dried leaves and young capsules of the Indian hemp, and a powerful narcotic.—*O'Shaughnessy, p.* 214. An infusion of pata root is a very useful bitter tonic and astringent. Dose, one to two ounces three times daily. Pata is also the name of Corchorus olitorious.—*Beng. Phar. p.* 304.

(7606) SIDA LANCEOLATA. THE LANCE LEAVED SIDA.

The root.

Malaytanghie vayr, TAM. | Vishabaddee, TEL.

This root, which is not unlike the common Liquorice root, in appearance, is intensely bitter and is prescribed in infusion together with Ginger in cases of Intermittent Fever, it is also considered as a stomachic, and is a useful remedy in chronic Bowel affections.—*Ains. Mat. Med. page* 87.

(7607) SIDA PERIPLOCIFOLIA, a native of the Malay Islands, was also one of those subjected to experiment by Dr. Roxburgh, who describes the plant as flowering and ripening its seed in the Botanic Garden at Calcutta, a great part of the year. " Its bark abounds in

serviceable flaxen fibres, and as it shoots quickly into long, simple twigs, particularly if cut near the earth, it answers well for procuring the fibre of good length for most purposes." Various species of Sida, as *S. asiatica, indica, graveolens,* and others, are extremely common in every part of India in the rainy season. Many of them, no doubt, contain fibre which might be turned to useful account.—*Royle Fib. Plants, page* 263.

(7608) SIDA RHOMBOIDEA AND SIDA RHOMBIFOLIA are the *sufed* and *lal bariala* of the natives of Bengal, where the plants are indigenous in the rainy season. The bark of both, according to Dr. Roxburgh, yields abundance of very delicate flaxy fibres, which he thought might be advantageously employed for many purposes. When the seed is sown thick on a good soil, the plants grow tall and slender, without branches, and are every way fit for such purposes.—*Royle.* Major Hanney sent from Assam to the Agri-Hortic. Soc., in Dec., 1851, some of the fibre of *Sida of rhomboidea,* which grows luxuriantly in that valley. Capt. Thompson thought from its length, its similarity to silk, and its great strength, that it would fetch a high price in England. The line (only half an inch in circumference) sustained, after exposure to wet and sun for ten days, 400 lb.

(7609) SIDA STIPULATA. SIDA HEMP. The most troublesome weed in Tavoy produces a very fine hemp or flax. There are two species *Sida acuta* and *Sida stipulata,* but they are not usually distinguished.—*Mason.*

(7610) SIDA TILIÆFOLIA. This species, *S. tiliæfolia,* referred at first by Dr. Roxburgh to *S. abutilon,* is cultivated for the purpose of its fibres in China. Some of its seeds were received many years ago at the Calcutta Botanic Garden, under the name of *King-ma,* from Pe-tsin, in the neighbourhood of which the plant is cultivated, for the sake of its fibre. Seeds were similarly received a few years ago by the Horticultural Society, and Dr. Royle saw a fine crop of the plants in the garden at Chiswick, which seemed about eight feet high. Some of these Dr. Lindley had steeped, in order to separate the fibres, and some were sent to Mr. Routledge in the year 1850, in order to try in his machine. Dr. Roxburgh notices "the fibre of this plant is strong and pliable, very silky in its nature, and the plant of very rapid and luxuriant growth, three crops being obtained in one year. It may be brought into England at the estimated price of £8 per ton, which is about one fifth of the price of Hemp of the best quality." Some of Dr. Roxburgh's original specimens, marked July, 1804, are still in the India House; the fibres are from four to five feet in length, and display a fine soft and silky fibre, as well as adapted for spinning as the Jute, but are apparently superior.

(7611) SIDEROXYLON (from σίδηρος and ξύλον), a genus of Plants belonging to the natural order *Sapotaceæ.* The species of this genus are natives of Africa, America, the East Indies, and Australia. They are evergreen trees, with axillary and lateral fascicles of flowers. They are remarkable for the hardness and weight of their wood, which sinks in water, and the genus has hence derived the name of Iron-wood. The *S. incime* (Smooth Iron-Wood) is a native of the Cape of Good Hope, and has long been cultivated in the greenhouses of Europe. None of the species however, are at all remarkable for beauty.—*Eng. Cyc.*

(7612) SIKAKUL. Root like a carrot, brought from Cashmeer; used in Ajmere as an aphrodisiac.—*Gen. Med. Top. p.* 150.

(7613) SILIGOREE, Dr. Hooker here noticed a wild hog, the first wild beast of any size he had seen in the plains, except the hispid hare (*Lepus hispidus*) and the barking deer (*Stylocerus ratwa.*) The hare he found to be the best game of this part of India, except the teal.—*Hooker, Him. Jour. Vol* I. *page* 369.

(7614) SILLARUS, STORAX LIQUID.

(7615) SILENE COMPACTA. SILENACEÆ. Catch Fly.—These are elegant flowering plants, of easy culture from seed, the flowers are of various colours, and require only the same treatment as the other species of Lychnis.—*Riddell.*

(7616) SILK.

Zyde, DUT.	Seta IT.
Soie, FR.	Ab reshum, PERS.
Seide, GER.	Seda, PORT. & SP.
Resum, Reshum, GUZ. and HIND	Schelk, RUS.

A soft shining filament, the product of several species of caterpillar, particularly the *Bombyx mori* or silk worm. Silk occurs in various forms. *Cocoons, knibs* or *husks,* are the balls as formed by the worm, about the size of a pigeon's egg, and of a golden yellow colour. *Raw silk,* the state when simply wound off the cocoons into skeins or hanks, is the thread composed of several fibres united by their natural gum. *Waste silk,* is that part which is first wound off the cocoons in the operation of reeling, and such cocoons as being eaten through by the worm, cannot be wound off the reel, but are afterward carded and spun. Silk husbandry is extensively prosecuted in Italy, France, China, Persia, Siam, and India. The descriptions of raw silks met with in the Bombay markets are China, Persian, Siam, and Bengal.—*Faulkner.* The Bombyx Huttoni has lately been brought to notice by Captain Hutton as producing a new variety of silk, spinning in all weathers, whereas the common silk worm is apt to be thrown off work by a passing cloud. It is thought that the new worm may prove commercially important.—*Friend of India.* A new process is announced of manufacturing silk directly from the bark of the Mulberry tree. The inventor's name is Signor Lotteri. The Exports from Madras, of silk, has reached 1666lbs.

value Rs. 6,569, and it is probable that the culture may be successfully carried on in the valleys of Neilgherries. Indeed, for some years past, experiments had been energetically carried on by the late Mr. Casamajor, and at present by Major Minchin: specimens of silk from Italian worms reared at Katy have been sent.—*M.E.J.R.*

Mysore.—The manufactured Silks sent to the Madras Exhibition of 1855, represented in a very partial degree the resources of the country in this useful as well as ornamental branch of Industry. The finest specimens of Madras silk manufacture, namely, the Shawls of Bangalore and the silk carpets of Tanjore and elsewhere very deservedly were awarded Medals. The Bangalore Shawls were very creditable from the harmony of colors and elegance of design. They have been much improved of late years both in quality of material and in beauty of pattern; white silk pocket handkerchiefs rivalling the China silk in softness and richness are also manufactured at Bangalore. The rearing of silk worms is carried on in all parts of the Mysore country, and great improvement has taken place in the quality of the silk at Bangalore, owing to the establishment, under the Mysore Government, of a farm, where mulberry trees from China and other countries have been introduced and where great attention has been paid to feeding the worms, &c. Still the state of the trade compared with that of the Bengal Presidency shows that much is yet to be done, in 1841, 1,175,308 lbs. of raw and waste silk were exported from the East Indies and Ceylon, of which nearly the whole was from Bengal. The exports from the Madras Presidency were, in 1853-4, 10,478 lbs. of raw silk and 1688 pieces of piece goods. In addition to the exports of this material, a great quantity is used in the manufactures of this country. The native cloths owe their beauty in a great degree to the richness of the silk borders. The satins, kincobs, &c. of Hyderabad are well adapted to Native costume, but hitherto little progress has been made in manufacturing articles for European costume, except in Bangalore. The silk of Tanjore and the lesser but elegant articles such as gimp, fringe, cords and tassels, braid for carriages, &c., are of every variety and of great excellence.—*M. E. J. R.*

Bengal.—Dr. Royle, writing on the silk culture in India, mentions that the Silk-worms which yielded the investments of Silk, were 1st. The large *Annual Worm* reared once in the year, and yielding its produce from only the middle of March till May. 2d. The *Desseey*, or *Indigenous Silk-worm* of Bengal, of which the cocoons are obtained throughout the year; that is, there are four or five collections annually; of these, the worm of the cold weather, or November breeds, and that of the dry weather, or March and April breeds, are superior to the others, from the more nourishing nature of the leaves at those seasons. 3d. The *China Silk worms* introduced into Bengal, which are next in estimation to the annual and country breeds; of these, both the yellow and white cocoons are abundant in the Radnagore district.

The Residents also described firstly, the *Nistry* tribe of worms, which is said to include three distinct kinds, the *madrassie*, *soonamooky* and *cranee*, and these yield a portion of what was formerly the Company's investment of Silk; secondly, the *Tusseh* Silk-worms, of which the *mooga*, *teerah*, and *bonbunda*, are described as different kinds; the cocoons of these are collected in September, and are called the Rain weather sorts; but there are others of the dry weather months which are denominated *dabba*, and *buggoy*. *Tarroy* is an inferior sort collected in December. The Tusseh, or Tussar Silk worm, is very extensively diffused, the Residents described the Worm as being reared in all the western forests from Ramghur to Midnapore. Dr. Roxburgh mentions it as a native of Bengal, Behar, and Assam, and that it is the same as the Bughy insect of other districts. The *Juroo* is also described as a variety, by Dr. Buchanan Hamilton, and as occurring in the districts of Bhagulpore and Dinajepore; by Col. Sykes it was found in the Bombay, and by Dr. W. Geddes in the Madras Presidency.

Mr. Hugon, Sub-Assistant to Captain Jenkins, Political Agent in Assam, describes six species of Silk-worm as being found in the central part of that province. Of these, the Mulberry Silk-worm, (Bombyx Mori); the Tusseh Silk-worm Saturnia (Phalæna) paphia and the Eria, or Arindy Silk-worm Saturnia (Phalæna) cynthia, were previously well known; but the others have been described by himself and by Dr. Helfer. The Mooga Silk-worm (Saturnia assamensis, Helfer), was also evidently known to the Resident (v. Report, p. 52). The Joree Silk-worm (Bombyx religiosæ, Helfer), is a new species discovered by Captain Jenkins on the Peepul tree (Ficus religiosa). This is said to yield a Silk certainly equal to that of the Mulberry Silk-worm.

Saturnia sylhetica, Helfer, is a native of the Kassia mountains, and of Silhet and Dacca. It also yields Silk, as do two other species, the wild Silk-worm of the central provinces, and another, which produces its cocoon upon the Mangoe tree. This the people of Malda gather, and mix with Arindy Silk cocoons in spinning.

There are probably other species in different parts of India, which may be found to yield useful products.

These wild Silk-worms may be thought by many unworthy of notice, as they do not yield the kind of Silk most valued in commerce; but they are more important than

they at first appear to be. We must remember that the culture of some in the forests, and the collection of all, affords employment to considerable numbers of the natives in the parts of districts least productive of useful occupation. They afford also clothing for many of the inhabitants, as Mr. Hugon informs us that Silk from the Eria, or Arindy worm (*Saturnia* (*Phalæna*) *cynthia*) is the daily wear of the poor in Assam, and is used by every class in winter. It is remarkable for its very great durability.

The Tussch Silk is still better known, having also afforded the natives in Bengal, &c. a coarse durable Silk, which is much esteemed in India, both for ladies' and children' dresses; for the latter especially, on account of its cheapness and durability. As an instance of the quantities in which the Tusseh Silk is produced in India, we may adduce the evidence of Mr. R. Montgomery of the Bengal Civil Service, in the Azimgurh district only, where 318,772 pieces of Tussch Silk are given as the quantity produced annually.

Mulberry Trees.—The White Mulberry (Morus alba) is infinitely to be preferred as food for the worms of the Bombyx mori, and this has been introduced from China into Europe, as well as into India. Morus Indica, the species most common in Bengal, is thought by Dr. Wallich to be only one of its varieties. Morus atro-purpurea is a species introduced into India from China, where it is employed as food for the Silk-worm, though Dr. Roxburgh states, that it had not been found to answer for that purpose in Bengal. Two varieties (one, the Doppa Foglia), of the Italian White Mulberry, received from St. Helena, were established in the East India Company's Botanic Garden at Dapooree, in the Bombay Presidency. The then Superintendent, Dr. Lush, forwarded to Calcutta young plants, which, in September 1833, were reported by Dr. Wallich to be in a flourishing condition. Two other species are common in the plains of North-western India, and others have been introduced there from Caubul and Cashmere; one distinct species occurs, moreover, in the Himalayas.

Col. Sykes has drawn attention to the great importance of introducing into India the Mulberry called Morus multicaulis, a distinct species or variety introduced by M. Perrottet into France, in 1821, from the Philippine Islands, where it had been brought from China. It is now thought by many, both in Italy and France, to be the most valuable sort for cultivation, and has become a favourite variety in America. It is said, besides growing easily, and affording abundance of leaves of the most nourishing kind, to be able to withstand a considerable degree of cold.

All the wild Silk-worms feed upon different trees, such as the Jujube, Ficus religiosa or Peepul, the Castor Oil Plant, Terminalia catappa some of the Laurel tribe, and others, which are found in almost all the forests of India.—*Boyle's Productive Resources of India.*

History of Silk trade with India.—Equal in antiquity to the growth of cotton was the production of silk in the countries of the East. Its limited extent, however, and the monopoly of this valuable traffic in the hands of the Phœnicians, and afterwards by the Persians, restricted its employment within the most confined limits. Until the time of the Roman empire, its very existence appears to have been unknown in the West; and when Dionysius, the imperial geographer, who visited the East in the first years of the Christian era, wrote an account of this new and beautiful product, he speaks of it as a precious web, finer than that of the spider, combed by the natives from flowers, and spun into rich garments of great price. Previous to the middle of the eighteenth century, Indian raw silk formed a very inconsiderable portion of the trade from the East. Its great inferiority to the Italian and French article was for a long period a great barrier to the profitable extension of this branch of Indian trade. The factors of the Company did no more than purchase the silk as it reached their hands from the three filatures, whence alone it came in those days. At Cossimbazar, Rungpore, and Commercolly, the natives grew large tracts of the common mulberry-plant, reared their worms, and reeled the produce of the cocoons; but with so small regard to the exigencies of the worms, and so little care bestowed upon the preparation of the silk, as to render it a most unprofitable and troublesome article in the hands of the European manufacturer; so much was this felt, that until the latter part of the last century, Indian silk was employed but for the manufacture of certain inferior minor articles of haberdashery, and never entered into the composition of satins, or silk piece-goods of any kind. One great cause of this inferiority was to be found in the careless method of winding the silk from the cocoons, which produced such inequality in the thread as to render it all but unserviceable. Besides this, it was loaded with gummy and other extraneous substances, and reeled without the least attention to colour or quality; so that it reached the buyer's hands in hanks comprising all sorts of shades. This part of their trade proved so annoying, and was attended with such fruitless results, that the Company were at one time on the point of issuing orders to cease all purchases of the article. Instead of acting on this first impulse, the Directors wisely made an effort to remedy the evil complained of, by sending to Bengal one or two persons acquainted with the Italian mode of reeling and assorting silk; these instructors were placed in the heart of the silk-districts, and appear, from after re-

sults, not to have laboured in vain. Inducements were at the same time held out to the ryots to extend the cultivation of the mulberry-plant, by allowing them all lands so used free of rent for two years, and afterwards assessing them very moderately. In this manner the silk-trade received an impulse hitherto unknown to it, and the exports of the raw article rose from 80,000 lbs. in 1750, to 320,000 lbs. in 1770. The partial success which had attended the introduction of a better mode of reeling silk induced the Company to attempt still further reforms; and we accordingly find that in the year 1771 a second supply of practical silk-reelers and mulberry-cultivators from Italy were dispatched to Bengal; proper filatures were established; a better mode of rearing the insects and growing the plants was introduced; and in addition to these measures, steps were taken to secure a supply of eggs from China, with the view of improving the breed of the Indian worms. Several years elapsed before these improvements were beneficially felt in the quality of the silks imported from Bengal; but that such was the case may easily be seen by the steady increase in the quantity taken by the manufacturers of England, which in 1785 amounted to 576,175 lbs. The greatest improvement effected by the Company at this period was the total abolition of the contract system, and the substitution for it of agencies throughout the silk-districts, by means of which supplies of the cocoons were constantly obtained from sub-agents called bekars, who received advances in money, and who, in their turn, engaged by similar means for the supply of silk-worms from the rearers in the different villages.

The vast improvements effected in England towards the end of the last century in the manufacture of cotton goods tended in a great measure to check the consumption of the more costly article of silk; and we find that from 500,000 lbs. weight of raw silk sold in 1785, the silk Company did not dispose of more than, on the average, 300,000 lbs. weight in the years 1800 to 1805. So much better were the silk transactions of the Company managed at this time, that in spite of this decline in the demand for their goods, their yearly profits gradually increased from a few thousands to the enormous amount of 132,982*l.* in 1801. The gradual decline to a certain date, in the imports of Bengal raw silk, from the cause already assigned, may be seen by the following list of exports to Great Britain, taken at intervals of ten years; and in the same may be observed the effect of the gradual relaxation of the Company's trading monopoly in favour of private merchants. In 1782 there were shipped to England from Bengal, 611,071 lbs.; in 1792 401,445 lbs.; in 1802, 114,744 lbs.; in 1812, 982,427 lbs.; in 1822, 1,042,617 lbs.; and in 1832, 956,453 lbs.

Some idea of the commercial value of thi branch of Indian trade may be formed from th fact, that between the years 1776 and 1785, th raw silk imported by the Company, and in th privileged tonnage by private traders, was wort 3,446,757*l.*; from 1786 to 1803, it amount ed to 5,221,596*l.*; and from 1804 to 181(to 3,115,044*l.*; being during these thirty five years almost equal to 12,000,000*l.* sterling Upon the last renewal of the East India Charte in 1833, which provided that the Compan should no longer engage in mercantile opera tions, their extensive and well-organised filature were put up for sale, and after some delay dis posed of to private parties. These establish ments were eleven in number, of which the fo lowing gave their names to the particular kind of silk produced by each of them, and by whic those varieties are to this day known in com mercial circles; they are Bauleah, Commercolly Cossimbazar, Hurripaul, Jungypoor, Radnagore Rungpore, Santipore, and Surdah. Besides th above, the Company possessed a number c hired filatures of less note.

The exportations of Bengal raw silk in 1814-1 amounted in value to 231,271*l.*; in 1827-8 t 855,398*l.* and in 1837-8 to only 465,451*l.* Bring ing down these figures to a more recent date, w find that the silk exports of Calcutta were, durin the years 1848-9 and 1849-50, to the value c 714,000*l.* and 655,000*l.* respectively.

Indigenous Silk Worms of India.—Beside the China, or mulberry silkworm, there ar several varieties of silk-spinning worms indige nous to India, of which mention is made in som of the earliest records of that country. Thes have been described by several scientific writers and are known amongst the natives as the mooga the arindy, the tussah, and the joree worms, a producing fibres, which, if not equal in commer cial value to those of the mulberry-worm, ar nevertheless esteemed and largely employe amongst the inhabitants of the districts in whic they are found. These insects inhabit vas tracts of forest in Upper Assam, in the Madra Presidency, and in that of Bombay; and th cloths made from the raw material are in ex tensive use amongst not only natives but Euro peans, who find them most economical anc durable for many purposes. Some idea may b formed of the extent to which these kinds o indigenous silk are produced, when it is stated that in 1837 there were in one district alone not less than 318,772 pieces of tussah silk manufactured. The food of the wild silkworm is obtained from the trees of the forests inhabited by them, and amongst those known as affording them nourishment are the leaves of the jujube the castor-oil plant, the peepul, or banyan-tree, some of the laurels, and a few other plants.

Bombay.—So early as 1795, some attempt ap pears to have been made at Bombay to introduce

the silk-worm, but evidently without effect; for until 1823 we hear nothing more of the matter, and then it seems to have been attempted at one of the public jails by the labour of the prisoners, the result of which appears to have been the preparation of a few bales of silk for local consumption. Later still, the zeal and industry of an Italian gentleman were brought to bear upon the subject, and under his directions a better cultivation of the mulberry plant, and a method of feeding and reeling was introduced, unattended with permanent results.

Madras.—In Madras this branch of industry met with great encouragement so long since as 1791. No efforts were spared to induce the natives to enter fully into the rearing of the worm and the growth of the plant; and, as the result shews, the success was, if not so great as in Bengal, still sufficiently encouraging.

China, History.—Silk is said by Chinese authors to have been known there for thousands of years. It has long been imported into India from China. The earliest notice, though there is some doubt about the passage, is in the Mahabharut where Cheenas, Hoonas, &c. are said to have brought silk, and silk-worms as presents to Yoodhistira.

Silk Worms and their products.—When the China silk-worm was first introduced into India as an object of culture we have no information; but what is called the indigenous (*desee*) silk-worm is carefully distinguished from the China worm; and there are several species of wild silk-worms, species of *Saturnia*, *Phalœna*, and *Bombyx*, all of which were shown at the Great Exhibition of 1851 with *Tussur*, *Moonga*, and *Eri* cloth. The former is much used in India by the natives, and is best known as an article of commerce, and has been used in Britain for parasols; in India it is esteemed for children's dresses. The Eri cloth is extensively used as an article of clothing by the inhabitants of Assam. The silk of Bengal was originally very inferior in quality, and very carelessly wound. The East India Company, in the year 1757, sent Mr. Wilder to improve the winding of silk; and in the year 1769 other Europeans, as drawers, winders, reelers, and mechanics. The filatures were all in Bengal, and to the Southward of 26° of N. lat., for the northwest provinces are much too hot and dry for the silk-worm. Experiments were for many years made on the western side of India to introduce the culture of the silk-worm, under an Italian, M. Mutti; but they have lately been abandoned from want of success. Some excellent silk is being produced in Mysore, and it is probable that the culture might easily be carried on in the valleys of the Himalaya.—*Royle. Arts. &c. of India, page* 496. Moorshedabad has long been a central mart for silk goods, and a variety of specimens of silk were sent from thence, and some satins (*mushroo*) from Benares, Cutch, and Hyderabad, chiefly in alternate species of different colours. On the Bombay side the culture did not succeed, and the raw material is imported from China and dyed, but the manufacture has not on that account been neglected. The weavers seem, in fact, to have paid an extra degree of attention to their art, and sent to the Exhibition of 1851, silk which is well woven, and in a variety of patterns, together with an excellent specimen (called *pytanee*) of double weaving, being red on one side and green on the other, and showing the colours and patterns very distinct. This was from Poona The silk, from Surat, Tanna, and Ahmednugger were also admired for their patterns, as well as the longees from Sindh. The silks from Cashmere attracted much attention, both from the substantial nature of the fabric, some of which is called tafeta, and for the moderate tone of the colours with which they are dyed. The flowered silks, or brocades, from Benares and from Ahmedabad, as well as those from Hyderabad, commanded notice for their richness and the happy disposition of pattern and combination of colours.—*Royle, Arts &c. of India, page* 497.

Mysore.—Surgeon Smith of the Madras Army, for many years in medical charge of the Mysore Commission, conducted experiments under his own superintendence, and the result of his observations contained in the following report may be relied on, as he spared no pains to make himself acquainted with the subject. General Sir MARK CUBBON, *Commissioner*. July. 1857

The cultivation of Silk is supposed to have been introduced into Mysore by Tippoo Sultan, and although the climate is evidently well calculated both for the growth of the Mulberry, and the development of Silkworms, the cultivation does not appear to have made any great progress until after the government of the country fell into the hands of the British in 1832.

The Mahomedans adopted the feeding and management of the worms and the reeling of the Silk as one of the few modes of gaining a livelihood to which they are not averse, purchasing the Mulberry leaves from the cultivators; and the Commissioner gladly encouraged the growth of Silk in every possible way, with a view of developing habits of industry among a class of men generally opposed to labor of any kind, unconnected with a Military life.

The open parts of the country alone seem to suit this cultivation, such as the Bangalore, Chittledroog, and open parts of the Astagram Divisions. None is grown in the Nugger, or in the Munjerabad sections of the Astagram Division, the climate is too damp in these last named Districts. Most of the Silk was formerly exported to Coimbatore and Tanjore, and a smaller

portion found its way to Bellary and Dharwar, for consumption in Native manufactures. At this time (1857), there is a considerable consumption of the raw material in Bangalore and Mysore in the manufacture of Silk Shawls, Handkerchiefs and Native Cloths, &c.

In 1841, four specimens of Silk grown in Mysore, were sent to Bengal, two of the specimens were purchased in the bazar and two were from cocoons purchased in the bazar, and privately and carefully reeled. The object being to find out the defects in the Mysore Silk, and to know if it would be valuable as an export in the state in which it is sold by the Natives. The following are Extracts from the Report: "One of the most apparent faults of this Silk is "its bad colour. This arises from the circum- "stance of the cocoons having been boiled in cop- "per pans instead of earthenware, and I should "imagine that at the time of reeling the Silk, "the water in which the cocoons were placed "was not changed often, as should be done. "This latter precaution would not only have "assisted to give the Silk a better colour, but "would have freed it somewhat more from the "gum, the superabundance of which renders "these specimens harsh and hard." It appeared from the above Extract that the faults of the Mysore Silk lay not so much in the article itself as in its mode of preparation.

A garden originally planted as a private speculation was taken by the Mysore Government in 1842, with a view to try how far Signor Mutti's proposal of growing Silk from standard Mulberry trees was likely to succeed in Mysore, and benefit the country. The larger and upper portion of the ground was planted with cuttings of the St. Helena Mulberry, and a few China ones, the lower and wet part, with Philippine, both grew well and for the first few years promised well. Eggs were obtained from Mr. Groves' Establishment at Chittoor, from an Establishment in the Neilgherries, and some of the annual March bund from Mr. Blechynder's Establishment in Bengal: these latter being annual worms, it was hoped would have proved a valuable auxiliary to the Mysore breed, and enabled us to feed from the standard trees, but in spite of every care and precaution they hatched on the eleventh day as in Mysore and from that time regularly produced their crops every fifty days. The Silk was certainly a great improvement on that of Mysore, but the worms were delicate and required more care and attention, so that I much doubt if they were ever extensively used by the Natives.

The Sub Peshkar of Bangalore, a man familiar with the country method of reeling Silk, was sent to Chittoor and placed under the tuition of Mr. Groves, who had an extensive plantation of Mulberries and experienced reelers. The man returned to Mysore well qualified for his post of Superintendent of the Government Garden. Reels of the best construction were made by Colonel Green and so expert did the Natives become, that in 1846, the following is the report of the Bengal Chamber of Commerce on the specimens sent for that purpose.

Report of the Silk Committee on specimens of Raw Silk, the produce of the Sirkar Gardens at Bangalore, forwarded by the Agricultural Society at Madras.

"Your Committee have examined these speci- "mens with great interest, and should be pre- "pared to give an unqualifiedly favourable opi- "nion on them, had the thread been a very little "stronger: as it is, it is remarkably even, round, "and free from knibs and gouts, and the colour "very pure and uniform, indeed, with the single "exception of being somewhat too fine, the pre- "sent are most admirable samples of Silk."

"Your Committee would however remark "that an opinion often prevails among such as "are not practically versed in the manufactures, "that the finer the Silk, the better and more "valuable, but it may be too fine, and the "present specimens, your Committee think, are "finer than it would be safe to prepare for the "English market, for the difficulty of unwinding "such Silk is extreme, and adds enormously to "the charge of preparing it for the weaver. A "Member of your Committee, Mr. Laidlay, ob- "serves that he has known in more instances "than one the most disastrous results from the "mistake of reeling the Silk too fine, for it will "not bear to be unwound by the machinery used "for the purpose in England.

"Your Committee however beg to add, that "these specimens are in every other respect un- "exceptionable, so clean, even, and beautiful, "that the reeler who prepared them may be pro- "nounced competent to produce Silk of the first "rate excellence, nearly, if not quite equal to "Italian. "The soil and climate too must cer- "tainly be favorable to the culture." (Signed) Robert Watson, J. W. Laidlay. Calcutta, March 1846.

To F. S. Gabb, Esq., Secretary, Agricultural and Horticultural Society, Madras. Sir,—The Honorary Secretary of the Calcutta Agricultural Society has handed to me two sample skeins of Raw Silk, the produce of Bangalore, and a copy of your letter 26th February to his address, with "Extract from Proceedings of a Meeting of your Society wherein the specimen of the Silk is ordered to be sent to the Chamber of Commerce here for report."

"Having laid such communication and the "samples before the Chamber, I am desired to "inform you that they consider the Silk very "beautiful, but the thread is too weak for free "reeling, if of stouter thread it would pay well at "the price you quote. Both sorts are too fine "for ordinary purposes and could not be re- "wound without great waste, even twice their

" thickness might be too fine to suit the English " market, the staple not being strong enough " to stand the action of the machinery used for " winding and preparing the article for the use " of the weaver, probably about 10 cocoons " would afford the best size to reel. The co- " coons from which these specimens were made " must have been very good indeed, equal to the " best annual cocoons of Bengal, but the thread " especially the white, is endy and it is not " twisted enough ; with improved implements, " and proper directions, the spinner should be " able to produce an article of superior charac- " ter and higer value."

" Though of minor importance I may here " mention that the skeins would be better if not " quite so thick. These weigh about 6 tolahs, " whereas the skeins generally made in India and " most approved in England weigh about 3 or 3½ " tolahs, a size which is attended with several " practical advantages," (Signed) W. Limong, *Secretary*. Calcutta, Bengal Chamber of Commerce, *April 25th*, 1846.

The brokers, Messrs. Norton, Thilburn and Co. of Saint Mary Axe, London, reported of some samples of the Silk sent to them in 1850, as follows," This Silk with care in the getting up " would prove a valuable substitute for many " other classes, and from its intrinsic qualities " would find a ready sale in this market." These Extracts prove the capability of Mysore to produce Silk of first rate quality. But until filatures conducted by Europeans are established as in Bengal but little of the Silk will ever find its way to the English market, At present the Natives find a ready sale in India for all they can produce, and it answers their purpose better to reel it roughly and sell it as they do, for although clean reeling will produce a greatly enhanced price, the proceeds of the Silk will be much less and the sale of the raw material not so certain as it is now. Since 1846 the average annual produce of Mysore has been about 10,000 maunds of 24 lbs. or 240,000 lbs weight, a quantity sufficiently large to attract attention to its cultivation.

The standard mode of cultivation failed for reasons explained in the following Extract from a letter to the Commissioner, dated 11th August 1849.

" When we consider the incessant demand for leaves made on the standard trees in consequence of the bi-monthly crops of silk which alone grow in Mysore, the cause of failure will be at once evident. The leaves of a plant are organs of respiration, digestion, and nutrition, a tree cannot be made to yield 5 or 6 crops annually without seriously impairing its vitality, if the leaves are stripped off a plant before the fruit has commenced ripening, the fruit will fall off and not ripen. If a branch is deprived of leaves for a whole summer, it will die, and not increase in size perceptibly, and this is exactly what has taken place with the standard trees at the Silk garden, they have aged, become woody, and throw out nothing but fruit unless pruned back to the stems, when an entire new set of branches is thrown out with an abundant crop of fine leaves ; these branches by the loss of their leaves age and die within the year, and the same process has to be renewed ; latterly the only mode of obtaining good leaves from the standards has been by cutting them down to the ground, the roots then throw up abundant fine shoots, a proceeding which in effect is returning to the bush system. On this subject I quote the following passage from a valuable little work by Count Dandalo on the " art of rearing Silk worms." He says—" It has been said, that in Asia they " obtain as many as twelve crops of cocoons in a " year. And some person made experiments, and " published some views on the subject ; stating, " that with us (that is in Italy) there might, at " least, be gathered two crops ; my experiments " on the contrary tend to prove, that it would be " a sure method of destroying the Mulberry trees, " and consequently the entire breed of Silk " worms. I cannot indeed bring myself strictly to " believe, that in Southern Asia it would be " possible to have such numerous crops of co- " coons. The southern part of China corresponds " very nearly, as to climate, with the Southern " parts of Persia, and yet there, according to the " illustrious Pallas, the boughs of the Mulberry " trees are cut only twice in the year, so as to " have in the same year two crops of cocoons. " In those climates they prune the small branches " twice a year, because the summer being long- " er, the Mulberry tree is more vigorous there " than it is with us. Here, on the contrary, the " Mulberry tree cannot even bear the stripping " of its foliage once a year without being injur- " ed, and certainly would die if stripped twice."

The Count is misinformed in regard to the number of crops annually. In Mysore, 6½ crops are the utmost ever obtained, each crop occupies 56 days, 33 in the worm, 12 in the cocoon, 11 in the egg, the insect requires food for 198 days in each year, where the succession is regularly kept up. The cultivation by standard trees is obviously not adapted to meet such an incessant demand. Of this, the Natives are perfectly well aware for Doctor Royle in speaking of the cultivation of the standard Mulberry, says, " This practice is not entirely foreign to the " Natives, as the Resident at Baulleah states that " the annual worm prefers the leaf of the shrub " which is well matured, to that which is young " and tender, and therefore he infers that it " would thrive better with the tree leaf than the " shrub leaf. He also says, that the tree is " cultivated in parts of the Rungpore and " Radnagore districts for the production of " cocoons. The Resident at Hurripal states, that

"there, the method of cultivation differs from that "in use about Baulleah and Malda, the leaves "being gathered only from standard trees, which "are preferred on account of the dryness of the "soil in that district."

The following are two Extracts from a paper taken out of an old Chinese work on the cultivation of Silk, of sufficient interest for insertion in this place. After describing at length the management of the worms for an annual crop, or a spring and autumn one at most, he says, "for if they (the Mulberry trees) are quite "stript one year, they die and fail entirely the "spring following." After speaking of the necessity for feeding the young worms every half hour during the first 24 hours of their life he says, "The reason why they take so much "pains to make these little insects eat so often, "is to forward their growth and make them spin "the sooner, the great profit which they expect "from these creatures depends upon this care, "if they come to their full growth in twenty-"three or twenty-five days, a hurdle covered "with worms, whose weight at first was a *mass*, "that is a little more than a drachm, will pro-"duce twenty-five ounces of Silk, whereas, if for "want of proper care and nourishment, they do "not come to their perfection in less than 28 "days, they will produce but twenty ounces, "and if they are a month or 40 days in growing "they will have but about 10 ounces." This is a most interesting fact, and applied to breeding in general, shows the vital importance of supplying young stock with abundant nourishment while growing: there is perhaps no other instance in nature, in which such an experiment could have been so accurately tried and its results ascertained with almost mathematical precision.

On the subject of the comparative merits of the standard and bush modes of cultivating the Mulberry, I wrote to the Secretaries of the Horticultural Societies of Bengal and Bombay. From the latter I received no reply, which I regret, for I was anxious to know how far Signor Mutti's plan had answered under his own superintendence. The Secretary to the Calcutta Agri Horticultural Society writes as follows: "The system of growing the Mulberry, as a "standard tree, has been tried in Bengal, and, "so far as the result of my enquiries enables me "to say, with as little success as has attended "the experiment of the St. Helena variety on "your side of India. The common bush Mul-"berry is very much preferred by the people at "Surdah, Commercally, Radnagore, and I be-"lieve, all other parts of Bengal, where Silk "cultivation prevails."

More than one private speculation with standard trees failed at Chittoor, and Conoor, under energetic and intelligent European superintendence. I have no reason to think that the experiment has failed from any want of care or attention on the part of the attendants, they have done their best, and if the Commissioner will refer to the report of the Bengal Horticultural Society on the specimens of Silk sent to Bengal in 1846, he will there see that the qualifications of the reeler at the garden are first-rate. I have lately found when obliged to hire reelers to wind off a large crop that it is not difficult to get very good reelers among the Natives, and the reason why the Natives do not practice reeling their own Silk cleanly and fit for the European market, is that it is not saleable in this country and there is a demand for all that can be produced reeled in the country fashion, independently of which the increased value of the Silk cleanly reeled will not compensate for the loss of weight and increased time and expenses of reeling.

The standard trees are all worn out and useless, they require to be replanted, and if replaced by young trees not a leaf should be taken from them for he next five years. A large portion of the garden is laid down with the common country bush Mulberry cuttings, of the St. Helena for standards planted at distances of 20 or 30 yards from each other among the bushes, and this I think is the proper way of growing standard trees, which thus planted, in no way interferes with the bush system, and at the same time affords food in seasons when, from want of water or other causes the bushes fail. The Philippine planted as bushes have not answered, though the leaf is large and nutritious. It is said by the Natives not to yield an equal weight of food on the same space of ground.

I beg respectfully to suggest to the Commissioner either that the entire garden be laid down in the country fashion, with standard trees at intervals as above described, or else that it be let out to Natives to be cultivated in their own way, keeping up the present breed of worms, which are very superior to their own in the bright colour of the Silk. Surgeon C. J. Smith. Bangalore, 11th August 1849.

At present, 1857, the cultivation of Silk is carried on by the Natives in their own way, and by the bush system which they have found practically the best. Captain J. Cunningham, *Secretary*.

Hyderabad in the Dekhan. The chief of the manufactures and the only one for which Warungul is famed is that of Persian carpets which are made of all sizes and of worsted cotton, or even of silk.

Silk cloth, of the width of the curtailed guz, is manufactured and sold for 12 annas a yard, but the quality is very inferior. It is dyed red with lac, green with indigo and turmeric, or yellow with turmeric alone. The *tusser* cloth manufactured is only half the value of the silk. *Cholees*, (women's boddices) are manufactured but not in sufficient quantity to supply the district, as they are imported.

The other manufactures in the Circar are *tusser* cloths at Hoosainpurty—and Chilpore silks at Mutwarrah.

The *Tusser* cloth—although the cocoons are the produce of the same insect as those of Bengal—bears no comparison in fineness or durability with the *tusser* cloth manufactured there. The silks are dearer, and the cottons of the same price as those produced nearer Hyderabad.—*M. L. S. J. No.* 35, 1849, *p.* 27.

Raw silk is imported from Madras and manufactured into sarees and women's breast cloths at Mutwarrah, Warungul, Maytpilly and Aimulwarrah, in Elgundel, at Maiduck and other Kusbahs. This manufacture is entirely for home use, and no great skill or taste is displayed by the weavers, the silk pieces are of a quality inferior to those sold at the same price in the Hydrabad bazar, and were it not for the transit duties, the manufacture would become extinct. The silk cloths are dyed red with the lac dye and yellow with turmeric; no other dyes are used. Tusser or jungle silk, the produce of a species of Saturnia, is made into sarees, punchees, and scarfs, at several towns of the Sircar of Warungul. But the chief seat of the tusser manufacture is the town of Mahdapore, on the right bank of the Godavery in the Ramgheer Sircar, where the moth that yields it is carefully reared, and from whence raw tusser silk is sent to other parts to be woven into cloth. The insect in its grub state is first fed on the tender leaves of the Careya sphærica, and, when more grown, on the leaves of the Pentaptera tomentosa; much watching and attention are bestowed in rearing the animal, subject as it is to destruction from birds, insects, and squirrels. The tusser cloths produced at Mahdapore are, in durability and fineness, very inferior to the cloths of the same kind manufactured in Bengal, they are dyed the same colour, and with the same materials as the silks, of which they are about one-half the price. At Mahdapore there are seventy to eighty families employed in rearing the insect and in the manufacture of the cloth, which is prepared principally for the Hydrabad market.—*J. M. L. S. No.* 38 of 1850 *p.* 224.

China. The two principal manufactures of China are, those of *silk* and *porcelain*, the originality of which was never contested, as the introduction of both into Europe is perfectly well ascertained; and could the Chinese urge no other claims to praise on account of their ingenuity, these two alone might serve to give them a high rank among the nations of the world. D'Herbelot justly considers that, as Rome obtained the silk manufacture from Greece, and Greece from Persia, so the last was indebted for it, according to the best Oriental authors, to China. The tradition, indeed, of the invention is there carried back into the mythological periods, and dates with the origin of agriculture. These two pursuits or professions, namely husbandry and the silk manufacture, the chief sources of food and clothing, form the subject of one of the sixteen discourses to the people, which have been before noticed. It is there observed, that "from ancient times the Son of Heaven himself directed the plough: the Empress planted the mulberry-tree. Thus have these exalted personages, not above the practice of labor and exertion, set an example to all under heaven, with a view to leading the millions of their subjects to attend to their essential interests." In the work published by imperial authority, called 'Illustrations of Husbandry and Weaving,' there are numerous woodcuts, accompanied by letter-press explanatory of the different processes of farming and the silk manufacture. The former head is confined to the production of *rice*, the staple article of food, and proceeds from the first ploughing of the land to the packing of the grain, the latter details all the operations connected with planting the mulberry and gathering the leaves, up to the final weaving of the silk.—*Mulberry Trees of China.*

Besides the common mulberry of China, which differs somewhat from that of Europe, they occasionally, in feeding the worms, have recourse to a wild specimen of the *morus* tribe, as well as to the leaves of another tree, supposed to be a variety of ash. The production of silk in the Chinese method, and with the aid of natives of the country, was tried experimentally by the East India Company at St. Helena; but has been abandoned, with the rest of their establishments on that island, since the expiration of the charter. The principal object, in the cultivation of the mulberry for feeding silkworms, is to produce the greatest quantity of young and healthy leaves without fruit. For this reason the trees are not allowed to exceed a certain age and height. They are planted at a convenient distance from each other, on the plan of a quincunx, and are said to be in perfection in about three years. The mulberry-tree for silkworms is chiefly cultivated in Che-keang, which province, together with the only three others that produce fine silk, namely, Keang-nan, Hoo-pe, and Sze-chuen, is crossed by the *thirtieth* parallel of latitude. Che-keang is a highly alluvial country, intersected by numerous rivers and canals, with a climate that corresponds pretty nearly to the same latitude in the United States of America. The soil is manured with mud, which is dug from the rivers, assisted with ashes or dung; and the spaces between the trees are generally filled with millet, pulse, or other articles of food. The time for pruning the young trees, so as to produce fine leafy shoots, is at the commencement of the year. About four eyes are left on every shoot, and care is taken that the branches are properly thinned, with a view to giving plenty of light and air to the leaves. In gathering these, they make use

of steps, or a ladder with a prop, as the young trees cannot support a ladder, and would besides be injured in their branches by the use of one. The trees, with their foliage, are carefully watched, and the mischiefs of insects prevented by the use of various applications, among which are some essential oils. The young trees of course suffer by being stripped of their leaves, which are the *lungs* of plants, and this is an additional reason for renewing them after a certain time. They endeavour in part to counteract the evil effects, by pruning and lopping the tree, so as to diminish the wood when the leaves have been stripped, and it is probable that a few leaves are left on. It is surprising, however, to observe how soon a tree in those climates will recover its leaves in the summer or autumn, after having been entirely stripped of them by a typhoon, or hurricane. Fresh plants are procured by cuttings or layers, or sometimes from seed. When the trees grow too old for the production of the finest leaves, and show a greater tendency to fruiting, they are either removed altogether, or cut and managed so as to produce fresh and young branches. Mr. Barrow, who observed the management of the trees and silkworms in Chekeang, confirms the usual Chinese accounts, by saying that "the houses in which the worms are reared are placed generally in the centre of each plantation, in order that they may be removed as far as possible from every kind of noise; experience having taught them that a sudden shout, or the bark of a dog, is destructive of the young worms. A whole brood has sometimes perished by a thunder storm." The chambers are so contrived as to admit of the use of artificial heat when necessary. Great care is taken of the sheets of paper on which the multitudes of eggs have been laid by the silkworm-moths; and the hatching of these eggs is either retarded or advanced, by the application of cold or heat according to circumstances, so as to time the simultaneous exit of the young worms exactly to the period when the tender spring leaves of the mulberry are most fit for their nourishment. They proportion the food very exactly to the young worms by weighing the leaves, which in the first instance are cut, but afterwards, as the insects become larger, are given to them whole. The greatest precautions are observed in regulating the temperature of the apartments, and in keeping them clean, quiet, and free from smells. The worms are fed upon a species of small hurdles of basket-work, strewed with leaves, which are constantly shifted for the sake of cleanliness, the insects readily moving off to a fresh hurdle with new leaves, as the scent attracts them. In proportion to their growth, room is afforded to them by increasing the number of these hurdles, the worms of one being shifted to three, then to six, and so on until they reach their greatest size. The hurdles, as well as the rest of the apparatus, were sent from Canton to St. Helena for the use of the Company's establishment there. When the worms have cast their several skins, reached their greatest size, and assumed a transparent yellowish colour, they are removed into places divided into compartments, preparatory to their spinning. In the course of a week after the commencement of spinning, the silken cocoons are complete, and it now becomes necessary to take them in hand before the pupæ turn into *moths*, which would immediately bore their way out, and spoil the cocoons. When a certain number, therefore, have been laid aside for the sake of future eggs, the pupæ in the bulk of the cocoons are killed by being placed in jars under layers of salt and leaves, with a complete exclusion of air. They are subsequently placed in moderately warm water which dissolves the glutinous substance that binds the silk together, and the filament is wound off upon reels. This is put up in bundles of a certain size and weight, and either becomes an article of merchandise under the name of "raw silk," or is subjected to the loom, and manufactured into various stuffs, for home or for foreign consumption. Notwithstanding the apparent simplicity of their looms, they will imitate exactly the newest and most elegant patterns from England or France. The Chinese particularly excel in the production of damasks and flowered satins. Their Silk crape has never yet been perfectly imitated; and they make a species of *washing* silk, called at Canton *ponge*, which becomes more soft as it is longer used.—*Davies Chinese, Chap.* xviii. *p.* 30. *Ed.* 1851.

Fortune spent a few days in the vicinity of Nan-tsin, and as it may be considered the centre of the great Silk country of China, I shall, he says, endeavour now to give a description of the cultivation and appearance of the mulberry trees. The soil over all this district is yellow loam, well mixed and enriched by vegetable matter; just such soil as produces excellent wheat crops in England. The whole of the surface of the country, which at one period has been nearly a dead level, is now cut up and embankments formed for the cultivation of the mulberry. It appears to grow better upon the surface and sides of these embankments than upon level land. The low lands, which are owing to the formation of these embankments, considerably lower than the original level of the plain, are used for the production of rice and other grains and vegetables. It is therefore on the banks of canals, rice fields, small lakes, and ponds, where the mulberry is generally cultivated, and where it seems most at home. But although large quantities of rice and other crops are grown in the silk districts, yet the country, when viewed from a distance, resembles a vast mulberry garden, and when the trees are in full leaf, it has a very rich appearance.

SILK.

The variety of mulberry cultivated in this district appears to be quite distinct from that which is grown in the Southern parts of China and in the silk districts of India. Its leaves are much larger, more glossy and have more firmness and substance than any other variety which has come under my notice. It may be that this circumstance has something to do with the superior quality of the silk produced in the Hoo-chow country, and is worthy of the notice of silk growers in other parts of the world. This popular variety is not reproduced by seeds and hence all the plantations are formed of grafted trees. Each plant is grafted from a foot or two feet above the ground, and rarely higher. The trees are planted in rows from five to six feet apart, and are allowed to grow from six to ten feet high only, for the convenience of gathering the leaves. In training them they are kept open in the centre; the general outline is circular, and they are not unlike some of those dwarf appletrees which are common in European gardens. The accompanying sketch gives a good representation of the habit and form of one of those trees which has attained its full size. The different methods of gathering the leaves in these districts are curious and instructive and show clearly that the cultivators well understand the laws of vegetable physiology. Leaves are not taken at all from plants in their young state, as this would be injurious to their future productiveness. In other instances a few leaves only are taken from the bushes, while the remainder are allowed to remain upon the shoots until the summer growth is completed. In the latter case the leaves are invariably left at the ends of the shoots. When the bushes have attained their full size, the young shoots with the leaves are clipped close off by the stumps, and shoots and leaves carried home together to the farm-yard to be plucked and prepared for the worms. In the case of young trees, the leaves are generally gathered in by the hand, while the shoots are left to grow on until the autumn. At this period all the plantations are gone over carefully, the older bushes are pruned close in to the stumps, while the shoots of the younger ones are only shortened back a little or allow them to attain to the desired height. The ground is then manured and well dug over. It remains in this state until the following spring, unless a winter crop of some kind of vegetable is taken off it. This is frequently the case. Even in the spring and summer months it is not unusual to see crops of beans, cabbages, &c., growing under the mulberry trees. During the winter months, the trees are generally bare and leafless. Those persons who are accustomed to live in countries with marked seasons, where the winters are cold, and where the great mass of vegetation is leafless, would not be struck with this circumstance in the silk country of China. But the view one gets in this country in the summer months, after the first clipping of the shoots, is curious, and striking. As far as the eye can reach, in all directions, one sees nothing but bare stumps. It looks as if some pestilential vapour had passed over the plain and withered up the whole of these trees, and the view is rendered still more striking by the beautiful patches of lively green which are observed at this time in the rice fields and on the banks of the canals. This system of clipping close in to the stumps of the old branches gives the trees a curious and deformed appearance. The ends of the branches swell out into a club like form, are much thicker there than they are lower down. After I had completed my inspection of the country near the town of Nan-tsin, I proceeded onwards to the west in the direction of Hoo-chow-foo. A few hours' sail on a wide and beautiful canal brought me within view of the mountain ranges which form the western boundary to the great plain of the Yang-tse-kiang, through which I had been passing for several days. The most striking hill which came first into view was crowned by a seven storied pagoda. It had a large tree by its side, equally striking in the distance, and which had probably been planted when the pagoda was built. I afterwards ascertained this to be the "maiden hair-tree" (Salisburia adiantifolia), a tree which attains a large size in this part of China, and is extremely ornamental.—*A Resid. among the Chi. p.* 343. The greater part of the silks and crapes used in this part of China are manufactured in the adjoining towns of Soo-chow and Kang chow. Flowered crape, however, a very beautiful production, is made in Hoo-chow. The process of manufacture is thus described by the Rev. Mr. Edkins in the "North China Herald':— "Two men are engaged at a loom in a cottage on the [illegible] stream. One sat at the end of the loom, using five pedals, and directing the shuttle and all that needed to be done with the threads that lay horizontal on the frame. The other was perched over head to superintend the pattern. This he did by means of vertical threads tied up in bundles, a large number of which, disposed transversely through the threads of the horizontal frame beneath him, were at his disposal. These he raised according to the requirement of the pattern, and thus caused that elevation in the threads on the frame which constituted the flowered part of the piece."—*Res. among the Chi. p.* 354. If there was little to notice in these temples with reference to Buddhism and its rites there were objects of another kind which soon attracted my attention. The halls and outhouses of the monastery seemed to be converted for the time into a place for feeding silkworms. Millions of these little animals were feeding in round sieves placed one above another

in open frameworks made for this purpose. So great was the number of the worms that every sieve, and there must have been many hundreds of them, was crammed quite full.' In one large hall I observed the floor completely covered with worms, I shall never forget the peculiar sound which fell upon my ear as I opened the door of this hall. It was early in the morning, the worms had been just fed and were at the time eagerly devouring the fresh leaves of the mulberry. Hundreds of thousands of little mouths were munching the leaves and in the stillness around this sound was very striking and peculiar. The place too seemed so strange; a temple —a place of worship with many huge idols, some from twenty to thirty feet in height looking down upon the scene on the floor. But to a Chinese there is nothing improper in converting a temple into a granary or a silk-worm establishment for a short time if it is required, and I suppose the gods of the place are supposed to look down with approbation on such scenes of peaceful industry. When from the large number of worms it is necessary to feed them on floors of rooms and halls, there is always a layer of dry straw laid down to keep them off the damp ground. This mode of treatment is resorted to when necessary, and not from choice. The sieves of the establishment, used in the frame work I have already noticed are greatly preferred. Whether the worms are fed on sieves or on the floor they are invariably cleaned every morning. All the remains of the leaf stalks of the mulberry, the excrement of the animals, and other impurities, are removed before the fresh leaves are given. Much importance is attached to this matter, as it has a tendency to keep the worms in a clean and healthy condition. The Chinese are also very particular as regards the amount of light which they admit during the period the animals are feeding. I always observed the rooms were kept partially darkened, no bright light was allowed to penetrate. In many instances the owners were most unwilling to open the doors, for fear, as they said, of disturbing them, and they invariably cautioned me against making any unnecessary noise while I was examining them. At this time nearly all the labour in this part of the country was expended on the production of the silk worm. In the fields the natives were seen in great numbers busily engaged in gathering the leaves; boats on the rivers were fraught with them; in the country market-towns they were exposed for sale in great quantities, and everything told that they were the staple article of production. On the other hand, every cottage, farm house, barn and temple, was filled with its thousands of worms which were fed and tended with the greatest care. On my way up from Hoo-chow-foo to Mei-chi and about the 23rd of June, I observed that many of the worms had ceased to feed and were commencing to spin. The first indication of this change is made apparent to the natives by the bodies of the little animals becoming more clear and almost transparent. When this change takes place, they are picked, one by one, out of the sieves, and placed upon bundles of straw to form their cocoons. These bundles of straw which are each about two feet in length, are bound firmly in the middle, the two ends are cut straight and then spread out like a broom, and into these ends the worms are laid, when they immediately fix themselves and begin to spin. During this process I observed the underside of the framework on which the bundles of straw were placed surrounded with cotton cloth to prevent the cold draught from getting to the worms. In some instances small charcoal fires were lighted and placed under the frame inside the cloth, in order to afford further warmth. In some of the cottages the straw covered with spinning worms was laid in the sun under the verandahs in front of the doors. In a few days after the worms are put upon the straw they have disappeared in the cocoons and have ceased to spin. The reeling process now commences and machines for this purpose were seen in almost every cottage. This apparatus may be said to consist of four distinct parts, or rather, I may divide it into these for the purpose of describing it. There is, first, the pan of hot water into which the cocoons are thrown; second, the little loops or eyes through which the threads pass, third, a lateral or horizontal movement, in order to throw the silk in a zigzag manner over the wheel; and lastly the wheel itself, which is square. Two men, or a man and woman, are generally employed at each wheel. The business of one is to attend to the fire and to add fresh cocoons as the others are wound off. The most expert workman drives the machine with his foot and attends to the threads as they pass through the loops over on to the wheel. Eight, ten, and sometimes twelve cocoons are taken up to form one thread, and as one becomes exhausted, another is taken up to supply its place. Three and sometimes four, of such threads are passing over on to the wheel at the same time. The lateral or zigzag movement of the machine throws the threads in that way on the wheel, and I believe this is considered a great improvement upon the Canton method, in which the threads are thrown on in a parellel manner. The water in the pan into which the cocoons are first thrown is never allowed to boil, but it is generally very near the boiling point. I frequently tried it and found it much too hot for my fingers to remain in it. A slow fire of charcoal is also placed under the wheel. As the silk is winding, this fire is intended to dry off the superfluous moisture which the cocoons have imbibed in the water in which they were immersed. During

he time I was in the silk country at this time was continually visiting the farm-houses and ottages in which the reeling of silk was going n. As silk is a very valuable production, it is eeled with more than ordinary care, and I ob-erved that in almost all instances a clean, ctive, and apparently clever workman was en-rusted with the care of the reeling process. The ld temple at Hoo-shan, which I visited again on ıy way down, was in a state of great excitement nd bustle. The quantity of silk produced here /as very large, and all hands were employed enerally all, rather averse to work of any kind, /ere obliged to take their places at the wheel or he fire. But as the silk was their own, they eemed, notwithstanding their habitual indolence, o work with hearty goodwill. On the following ıorning, when I awoke, I found myself quietly at nchor close by the west gate of Hoo-chow-foo, ıy boatmen having worked all night. I spent he next few days in the country to the north-/ard bordering on the T'aihoo lake, and partly ear the town Nan-tsin being anxious to see the nd of the silk season. About the eighth, or :om that to the tenth of July, the winding f the cocoons had ceased almost everywhere, nd a few days after this there was scarce-y a sign of all that life and bustle which s visible everywhere during the time that he silk is in hand. The clash of the winding-ıachines, which used to be heard in every ottage, farmhouse, and temple, had now ceased ; he furnaces, pans, and wheels, with all the ther parts of the apparatus in common use uring the winding season, had been cleared way, and a stranger visiting that country now ould scarcely have believed that such a busy ustling scene had been acting only a few days efore. During my peregrinations in the silk ountry I made many inquiries amongst the natives as to the price of raw silk in the districts /here it is produced. At Meiche the price was aid to range from twelve to eighteen dollars for 00 taels of silk. At Hoo-chow and Nantsin, /here the silk is of a superior quality, the rices in 1855 were from eighteen to twenty two ollars for 100 taels. The price of raw silk ke that of every thing else, no doubt depends ı a great measure upon the supply and demand, nd varies accordingly.—*A Res. among the Chi.* . 372.

The Honorable Mr. Morrison tells us that the ulberry is cultivated in all the provinces f China, except the most northerly, and lk is raised wherever the tree grows. The est raw silk, called *tayssam*, comes from the rovince of Hookwang ; the *tsailee* also comes om that province and Cheaking ; both kinds are alled Nanking raw silk, and are chiefly exported o England. In 1833-34, the price of the best orts was from £ 300 to £ 350 per pecul, and he annual exportation was between ten and twelve thousand bales ; in 1836-37, it was upwards of twenty thousand peculs, much of which was shipped off at $ 500 per pecul, since that period, for some undiscovered reason, the quantity brought to market has fallen off, and although the prices range between $ 400 and $450, still the whole amount hardly exceeds 5000 bales in a twelve month. In the new tariff the duty is the same on the raw silk from all the provinces ; for it is probable, that as the trade extends at Ningpo and Shanghae, inferior qualities of silk will be sent abroad ; indeed, if the exportation of silk and tea does not increase, it is difficult to see with what commodities the Chinese are to buy the large amount of foreign goods that are likely to be brought to the new ports. The Nanking raw silk exported the past year will average $ 450 per pecul, or $ 100 higher than it is set down in the statement. The waste or refuse raw silk goes entirely to India. *Silk organzine* is "formed of two, three, or more singles (*i. e.* reeled threads after being twisted), according to the substances required, twisted together in a contrary direction to that of which it is composed are twisted." It is included in the statements of trade under the name of silk thread. Organzine is also called *thrown silk*, though there may be some difference between the two, as it is said organzine is not made by the Chinese ; it is used in weaving piece goods. *Silk thread and ribbons* go to the United States, and South America. *Silk* piece goods of all kinds are shipped for the most part to the United States, Mexico and South America ; but considerable quantities go also to England chiefly for re-exportation : one seventh of the total exportation in 1836-7 was in English ships. Instead of the annual export of $400,000 stated in the Table, it should be one million of dollars, and the duties put at $ 30,000. Most of the various descriptions of silk piece goods usually exported are enumerated in the Table ; there are a few others, as gauze, crape shawls, levantines, taffeta, but all description of them is here omitted. — *Morrison.*

The manufacture of silk is original among the Chinese as well as those of porcelain and lacquered ware, and in neither of them have foreigners yet succeeded in fully equalling the native products. The notices of the cultivation of the mulberry and the rearing of silkworms found in Chinese works have been industriously collected and published by Mr. Julien by orders of the French government. From his work it appears that credible notices of the culture of the tree and manufacture of silk are found as far back as B.C. 780 ; and in referring its invention to the Empress Siling, or Yuenfi wife of the emperor Hwang-to, B. C. 2602, the Chinese have shown their belief of its still higher antiquity. "The Shi King contains this distich : The legitimate wife of Hwangti named Siling

shi began to rear silkworms." The best silk is found in the provinces of Sz'cheun, Hupeh Chehkiang, and Kiangnan, but every province south of 45° N. produces it of different degrees of fineness. Probably the kind called *tsatle*, brought from Hupeh, is the finest silk found in the world. While the worms are growing, care is taken to keep them undisturbed, and they are often changed from one hurdle to another that they may have roomy and cleanly places; the utmost attention is paid to the condition and feeding of the worms and noting the time for preparing them for spinning cocoons. Three days are required for them to spin, and in six it is time to stifle the larva; and reel the silk from the cocoons; but this being usually done by other workmen, those who rear the worms inclose the cocoons in a jar buried in the ground and lined with mats and leaves, interlaying them with salt, which kills the pupæ and keeps the silk supple, strong, and lustrous; preserved in this manner, they can be transported to any distance, or the reeling of the silk can be delayed till convenient. Another mode of destroying the cocoons is to spread them on trays, and expose them by twos to the steam of boiling water, putting the upper in the place of the lower one according to the degree of heat they are in, taking care that the chrysalides are killed, and the silk not injured. After exposure to steam, the silk can be reeled off immediately, but if placed in the jars, they must be put into warm water to dissolve the glue, before it can be unwounded. The raw silk is an article of sale; the sorts usually known in the Canton market are tsatle, taysaam, and Canton raw silk. The loom is worked by two hands, one of whom sits on the top of the frame, where he pulls the treddles, and assists in changing the various parts of the machine. The workmen imitate almost any pattern, excelling particularly in crapes, and flowered satins and damasks, for official dresses. The common people wear pongee and senshaw, which they frequently dye in gambier to a dust or black color; these fabrics constitute most durable summer garments, and the pongee becomes softer by repeated washing. Many of the delicate silk tissues known in Europe are not manufactured by the Chinese, most of their fabrics being heavy. The *lo* or law is a beautiful article, used for summer robes, musqueto curtains, festoons and other purposes, but is seldom sent abroad. The English words *satin*, *senshaw*, and *silk*, are probably derived from the Chinese terms *sz'tiin*, *sensha* and *sz*,' intermediately through other languages.—*Williams' Middle Kingdom, Vol.* I. *page* 123.

Silk, in Europe.—The discovery of the uses to which the cocoon of the silkworm might be applied, appears to have been first made in China: the written records of that country declare that an Empress was the first to unravel the filmy thread, and to work it into a web of cloth, and this is stated to have taken place 2,700 years before the Christian era. However this may be, it is a fact that when the existence of the silken fabrics of China became known in other countries, the manufacture was not in its infancy and imperfectly executed, but had attained a degree of excellence which proved a long and successful practice of it among the Chinese. Such indeed was its importance, that the very people and their country are named *Seres*, and *Serica*, in ancient writings, from the Chinese word *Se*, which signifies *Silk*. At length, about the middle of the sixth century, the western world received the great boon of a supply of silkworms' eggs: these were conveyed from China to Constantinople by two Persian monks, who had gone to the East as missionaries, and had observed in China the various processes connected with the rearing of the silkworm, the nature of the trees on which they fed, and the preparation of the silk. This occurred about the year 552, in the reign of Justinian, who gave every encouragement to the introduction of the valuable insect. The eggs were secretly conveyed from China within a hollow cane: at the proper season they were hatched, and the caterpillars were fed with the leaves of the wild mulberry tree. The monks continued to superintend, at Constantinople, the rearing of the insects, and the whole process of manufacturing the silk. From this small commencement the myriads of silkworms have sprung, which throughout Europe and western Asia have met the demand for silk, which has gone on increasing from that time to the present.

The silkworm in Europe, is the caterpillar of the mulberry tree moth (*Bombyx mori*) belonging to the tribe of mealy-winged nocturnal insects, of which in the summer evenings we see so many examples. The eggs of this moth are smaller than grains of mustard seed, very numerous, slightly flattened, yellowish at first, but changing in a few days to a blue or slate colour. In temperate climates they can be preserved through the winter without hatching until the time when the mulberry tree puts forth its leaves in the following spring. This tree forms the entire food of the caterpillar, and seems almost exclusively its own; for while other trees and vegetables nourish myriads of insects, the mulberry-tree is seldom attacked by any but this insect, which in many parts of its native country, China, inhabits the leaves in the open air, and goes through all its changes without any attention from man, whose only care is to gather in the harvest of silk cocoons at the right season. In some parts of China, however, the silkworm requires the same care in the way of shelter, feeding, and nursing which in other countries is found necessary to ensure success. The common mulberry-tree (*Morus nigra*), so well known in Great Bri-

tain, is not the best species for the nourishment of the silkworm, although the caterpillar feeds readily on the leaves. The whitefruited mulberry, *M. alba*, a native of China, is the best, and is greatly preferred by the insect. It is now cultivated in many parts of Europe, frequently as a pollard by road sides. It comes into leaf a fortnight earlier than the black mulberry, which is an advantage in the culture of silkworms. The white mulberry does not thrive in Britain, the winters being too severe. There is another variety of mulberry, called the *Philippine* mulberry, which is a favourite in the south of France, on account of the size and quantity of the leaves, and the ease with which it can be propagated. In the south of Europe mulberry leaves are sold by weight in the market, and the buyer chooses them either young or mature, according to the age of the insects which are to feed on them. Young worms are fed on tender leaves, while full grown caterpillars require the stronger nutriment of the mature leaf. Attempts have been made to store food for the silkworm by drying the leaves in the sun, then reducing them to powder, and placing the latter in jars. This powder moistened with water is eaten with avidity by the silkworm; and may prove a valuable resource in late seasons, or under circumstances which affect the principal crop. It is even thought that three or four crops of cocoons per year may be obtained even in northern climates, by keeping successive hatchings of eggs in warm rooms, and supplying the worms with this food during winter. The silkworm, when first hatched, is about a quarter of an inch long, and of a dark colour. If supplied with appropriate food it remains contentedly in one spot: this is the case throughout its changes, so that there is no trouble in retaining it within bounds, as there would be with some other caterpillars. After 8 days' feeding and rapid increase of size, it prepares to change its skin, the first skin having become too small for its body. It remains 3 days without food, during which time a secretion forms on the surface of the new skin, which helps the caterpillar to cast off the old one; but the operation is further facilitated by silken lines which the insect casts off and fixes to the adjacent object: these hold the old skin tightly, while the caterpillar creeps out of it. The whole covering of the body is thus cast off, including that of the feet, and of the teeth and jaws, but it is done with difficulty, and sometimes the skin breaks, and a portion of it remains attached to the hinder part of the body, compressing it, and usually causing death. The newly moulted worm is pale in colour, and wrinkled; but it immediately recovers its appetite, and grows so rapidly that the new skin is soon filled out, and in 5 days another mould becomes necessary. Four of these moults and renewals of the skin bring the caterpillar to its full size, when its appetite becomes voracious, and the succulent parts of the mulberry-leaves disappear with extraordinary rapidity. The insects is now nearly 3 inches long; its structure consists of 12 membranous rings, which contract and elongate as the body moves. There are 8 pairs of legs; the first 3 pairs being covered with a shelly or scaly substance, which also invests the head. The mandibles are strong, and indented like a saw. Beneath the jaw are 2 small orifices, through which the insect draws its silken lines. The silk is a fine yellow transparent gum, secreted in slender vessels, which are described as being wound, as it were, on 2 spindles in the stomach; these vessels, if unfolded, would be about 10 inches long. The insect breathes through 9 pairs of spiracles distributed along the sides of the body. The caterpillar has 7 small eyes near the mouth; the 2 spots higher up are not eyes, but portions of the skull. Arrived at maturity, the caterpillar is of a rich golden hue; it leaves off eating, and selects a corner in which to spin its cocoon. It first forms a loose structure of floss-silk, and then within it the closer texture of its nest, of an oval shape: here the caterpillar remains working until it is gradually lost sight of within its own beautiful winding-sheet. Taking no food, and emitting this large quantity of silk, its body diminishes one-half, and on the completion of its cocoon it changes its skin once more, but then becomes an apparently inanimate chrysalis, or aurelia, with a smooth brown skin, and pointed at one end. It remains in this corpselike state for a fortnight or 3 weeks, when it comes forth a perfect winged insect—the silk moth. In escaping from the cocoon it pushes aside the fibres, first moistening the interior of the cocoon with tasteless liquid from its mouth to dissolve the gum which holds the fibres together. The mouth has no teeth, therefore it cannot gnaw its way out as generally supposed. In the perfect form, the insect takes no food, and only lives 2 or 3 days: the female dies soon after laying her eggs, and the male does not long survive her. The common silkworm is not the only caterpillar from whose cocoons silk has been obtained for manufacturing purposes; but it is so superior in the quality and quantity of its silk to all other insects, that small mention is made of any other. The larvæ of many European moths produce a strong silk, and the native silkworms of America yield a material which has been manufactured into handkerchiefs, stockings, &c. by the inhabitants of Chilpancingo, Tixtala, and other places of South America. The ancient Mexicans used the internal layers of white cocoons, which strongly resemble Chinese paper, as a material for writing on. A quantity of inferior silk is obtained in India from the Tusseh and Arindy silkworms, both natives of Bengal. The first affords a coarse dark-coloured silk, which is woven into

a cheap durable cloth ; the second yields a delicate flossy silk, which cannot be wound from the cocoons, and is therefore spun like cotton. Of this, a coarse kind of white cloth is manufactured, which is loose in texture, but so durable that it can scarcely be worn out in a life-time. The domestic treatment of the silkworm has been brought to great perfection in Italy. Formerly the eggs were hatched at uncertain periods, depending on the natural warmth of the season, or they were put in manure-beds, or were worn in little bags about the person next the skin. They are now hatched in an apartment heated to the proper degree by a stove ; but they are first washed in water, and afterwards in wine, to separate light eggs, as well as dirt, and the gummy envelope which surrounds the heavy ones. The temperature of the hatching-room is at first 64°, but is gradually raised 1 or 2 degrees daily, until it reaches 82°, which it is not to exceed. Pieces of coarse muslin, or of white paper pierced with holes, are placed over the eggs when they are about to be hatched. Through these the worms creep to the upper surface, and are removed as soon as possible to a cooler place. Young leaves and sprigs of mulberry are laid upon the muslin or paper, when the worms eagerly settle on the leaves, and can thus be transferred to trays, and removed to the nursery. This is a dry room of regulated warmth, with windows on both sides, so that free ventilation may be attainable. Chloride of lime should be in use to purify the air, and a thermometer and hygrometer to regulate the heat and moisture ; the latter is apt to abound where silkworms are kept, and is very prejudicial to them. Moist exhalations arise from the leaves and from their bodies ; fermentation, also, soon takes place if litter and dung be not speedily removed from their trays ; these are fertile sources of disease among the worms, and may carry off thousands in a day. One of the diseases to which silkworms are liable is of an extraordinary character, consisting of the formation of a minute cryptogamous plant of mildew within the body of the living insect. Damp and fermenting food and litter produce, in the first place, among the fatty matter of the body of the caterpillar, an infinite number of sporules supported by minute stems. These increase to such a degree that the vegetation soon pierces the skin, gives a general mealy appearance to the body of the caterpillar, ripens its seed, which is borne by the winds to every part of the nursery, carrying contagion with it, and at length causes the death of the worms. The dead bodies of worms or moths (for the insect is infected in all stages) are sources of contagion unless immediately destroyed. This disease is called *Muscardine* in France, *calcinetto* in Italy ; the French name arises from the resemblance of the diseased caterpillar to a mealy kind of sugar-plum made in Provence, and sold by the name of muscardine ; the Italian name also refers to the chalky or mealy surface of the skin. Various fumigations and washes have been tried, in order to purify infected nurseries, and to preserve others from the ravages of this malady ; a solution of blue vitriol (sulphate of copper) applied to the wood-work, frames, &c. of the nursery is of great use in destroying the seeds of the fungus, but nothing is so good a preservative as rigid attention to cleanliness and good ventilation. The improved means, first employed in Italy, for preserving the health of these valuable insects, are due to Count Dandolo, who gave particular and scientific attention to the subject, and superseded many an absurd custom in the rearing of silkworms. According to his method wicker shelves are arranged in a room at convenient distances, and are lined with paper on which the worms are placed. Such worms only are placed together as have been hatched at the same time, the space allowed them being, for each ounce of egg, 8 square feet during the first age, 15 feet for the second age, 35 feet for the third age, 82½ feet for the fourth, and about 200 feet for the fifth age. The mulberry-leaves are chopped in order to present a large number of fresh-cut edges to the young insect. Four meals a-day, as a regular rule, and luncheons between when the worms are particularly voracious, is the liberal allowance for their subsistence. The temperature at which silkworms are healthiest appears to be from 68° to 75°, though they are able to bear a much higher temperature. Alternations of heat and cold are exceedingly injurious to them. When the silkworms are about to spin they are provided with little bushes of broom, heath, or other flexible substance, which are arranged upright between the shelves, their tops being bent into an arched form by the shelf above. The bushes are spread out like fans, to allow plenty of space for the cocoons ; for if crowded, the worms are apt to form double cocoons, two working together, and these are worth only half the price of single cocoons. Specimens of these bushes, laden with cocoons, appeared in the Great Exhibition, like diminutive trees bearing golden fruit. There were also illustrations in abundance of the advanced state of silk culture in France, and of the success of a series of systematic attempts which have been made in that country to improve the breed of silkworms, and to lessen their liability to disease. The *Central Society of Sericiculture of France* exhibited beautiful specimens of silk, remarkably pure in colour, strong, and lustrous. In the department of the Drome, where the culture is so extensive that upwards of 2,000,000 of mulberry-trees are required to supply the food of the myriads of worms, the method of managing the insects is slightly different from that which we have described. Instead of wicker shelves lined with paper, large bam-

boo-like rushes which grow on the banks of the Rhone, are cut down, split open, and attached together so as to form long cane beds about 2½ feet broad, called *claies*. These are arranged one above another on a rude frame-work erected throughout the chamber, spaces being left at intervals as passages for the attendants to traverse. The worms, as soon as they are hatched, are strewed among the *claies*, and the mulberry leaves at the proper moment scattered over and amongst them. The attendants make use of a short ladder to ascend to the higher *claies*. In other establishments the *claies* are arranged so as to hang from the circumference of large wheels placed at each end of the apartment; by turning these wheels the ranges of shelves rise and fall, and are transferred from side to side at the pleasure of the attendant. British India possesses the climate and the abundance of labour favourable to this undertaking. accordingly, we find the culture of the silkworm spreading and improving in that country. In Bengal there are 8 or 10 principal factories or *filatures*, each employing from 3,000 to 10,000 persons, and the results of the Great Exhibition prove the fine quality of the silk obtained. The manufacturing treatment of the silk, when the labours of the silkworm are over, is as follows:—When the crop of cocoons is complete it is gathered from the bushes, and bout one-sixtieth part is set aside for the production of eggs, the finest cocoons as to web and colour being selected for this purpose, A difference of weight generally determines which are the cocoons of male, and which of female insects: the latter are heavier and rounder than the former. The cocoons intended to produce eggs are preserved in a very dry room, and in about 10 days, they lose in weight to the amount of 7½ per cent. The main crop of cocoons is next sorted into 9 qualities, known in the factories as—1. *Good cocoons*, which are strong, firm, almost equally round at both ends, not very large, but free from spots. 2. *Calcined cocoons*, in which the worm has died *after* having completed its work, and is reduced to a powdery substance. 3. *Cocalons*, which are larger and less compact than good cocoons. 4. *Choquettes*, cocoons in which the worm has died *before* finishing its work. 5. *Dupian*, or double cocoons, difficult to unwind, and often kept for seed. 6 *Soufflons*, cocoons of so loose and soft a texture that they cannot be unwound. 7. *Pointed cocoons*, in which one end rises in a point, which breaks off after a little silk has been unwound, and so spoils the thread. 8. *Perforated cocoons*, from which the moth has escaped. 9. *Bad choquettes*, in which the silk is spotted, rotten, and blackish in colour. The vitality of the chrysalis is destroyed previously to unwinding the cocoons: this is done either by exposure to the sun, or by artificial heat, such as that of an oven after the bread is withdrawn. The floss silk is removed from the cocoo by opening it at one end and slipping out th cocoon. In reeling, it is necessary to use cocoon of one quality, as different qualities require diffe ent treatment. The natural gum of the cocoons softened by immersion in warm water, kept the proper temperature by a charc al fire, or b a steam pipe. After they have remained in for a few minutes, the reeler (generally a woman gently stirs up or brushes the cocoons with short birch-rod, and to this the loose threads the cocoons adhere, and are thus drawn out the water. They are then taken 4 or 5 togethe twisted with the fingers into one thread (as man as 30 can be wound together) and passe through a metal loop, which rubs off dirt an impurities; it then passes on to the reel, whic has a slight lateral motion, so that the threa of one revolution does not overlay the other If it were allowed to do so, the threads woul be glued together before the gum had time t harden by exposure to the air. When any singl thread breaks or comes to an end, its place i supplied by a new one, that the united threa may be of equal thickness throughout. Th new thread is merely laid on, and adhere to the rest by its native gum, and as th filaments are finer near their terminatio than at the commencement, it is necessar to add other cocoons before the first set i quite exhausted. The cocoons are not entirel wound off, but the husk containing the chrysali is used, together with the floss silk, under th name of *waste*. Improved methods of reeling ar introduced from time to time, but they are o the same principle as the above. The length o filament yielded by a single cocoon is 300 yards though some have yielded upwards of 600 yards Eleven or twelve pounds of cocoons yield on pound of silk, from 200 to 250 cocoons going t the pound weight: thus about 2,817 cocoons ar included in that quantity. The reeled sil is made up into hanks for sale and use. Th form and contents as well as the quality of thes hanks differ according to the quarter whenc they are received.—*Tomlinson*. See BOMBYCIDÆ MORUS, MULBERRY: SATURINA.

(7617) SILK CARPETS. At the Madra Exhibition of 1855, some very handsome specimens were contributed by the Tanjore and Hyderabad Local Committees, and His Highness th Rajah of Tanjore exhibited a very large silk carpet (No. 253) intended as a present for Her Majesty Queen Victoria. The colors were brilliant, the pile close and velvety, and the pattern harmonious. The Jury considered His Highnes entitled to a 1st Class Medal.—*M.E.J.R.*

(7618) SILK COTTONS. The species of Bombax, which are remarkable for their gigantic stature and their splendid inflorescence, on account of their capsules, which, on bursting, display a flocculent substance, are often mistaken by travellers for cot-

ton, and the tree is hence called *cotton tree*. But as this substance is more silky than cotton, it has been distinguished by the name of *Silk Cotton*. It differs also in not spinning like cotton. Some difficulty, therefore, is experienced in making use of this very abundant cotton like produce; but Mr. Williams, of Jubbulpore, has succeeded in spinning and weaving some of it so as to form a very good coverlet. It might be easily made use of for stuffing pillows, muffs, or coverlets, for wadding, or for conversion into half-stuff for paper-makers, perhaps for making gun-cotton. In the 'Trans. of the Agri-Hortic. Soc.,' iii. p. 274, there is a report from the Society of Arts on two pieces of cloth made from the Sinool or Silk Cotton tree; and it is observed that, from the shortness of the staple of the down, and its elasticity, it could not be spun by cotton-spinning machinery.—*Royle*. At the Madras Exhibition of 1855, small samples of the silk cotton from the *Bombax*, *Ochroma lagopus*, *Calotropis* and *Cryptostegia* were exhibited, but they appear to have been put to no other use than stuffing pillows; they might be employed for the manufacture of paper, and the silky down of the Cryptostegia being very strong might be applied to some textile manufactures. —*M. E. J. R.* Thus, the products of several plants, the *Bombax*, *Eriodendron*, the Ochroma lagopus, the feathery silk-like material in the pods of the Calotropis gigantea, and the Cryptostegia are so named. A trial has been given to the cotton of Calotropis gigantea, and Cryptostegia, as a material for cloth and cord, but their principal use hitherto has been for stuffing pillows: they might be employed as a material for making paper. There are two genera of plants, known under these names, Cotton tree or Silk cotton tree; the red and white cotton trees, common in many parts of India. They belong to the natural family Byttneriaceæ.—The red cotton tree and silk cotton tree, Bombax malabaricum, and white cotton tree, Eriodendron anfractuosum. Some difficulty is experienced in making use of the very abundant floss or cotton like produce of these trees; but it has been spun into cloth, and it might be employed for stuffing pillows, muffs, or coverlets for wadding, or for conversion into half stuff for paper makers: perhaps for gun cotton. From the shortness of the staple of the down, and its elasticity, it could not be spun by cotton spinning machinery.—*Royle, Mason.*

(7619) SILK GOODS. Those of China, go mostly to the United States, and raw silk to England, the supply is not equal to the demand, and only about ten thousand bales are now exported, while upwards of twenty thousand were sent off, mostly to England, in 1836, some of which rated as high as $500 a peeul. The refuse raw silk goes to India. The exportation to the United States for making silk thread is trifling. Silk goods are shipped to the United States, Mexico and South America, and elsewhere, to the annual value of about a million of dollars; they consist chiefly of pongees, handkerchiefs, crape-shawls, scarfs, sarsenet, senshaws, levantines and satins; ribbons, sewing thread, and organzine or thrown silk, are not much shipped. The silk trade is more likely to increase than any other branch of the commerce, after tea, and the Chinese can furnish almost any amount of raw and manufactured silks, according to the demand for them.—*Williams.*

(7620) SILK GUT OR SILKWORM GUT. A hard, white, transparent thread, about a foot in length, made in Italy and China, from the intestines of the silk worm, and used for angling. —*Waterston—Faulk.* *Silkworm Gut* is prepared for the angler as follows:—A number of the finest silkworms are selected when they are about to spin: they are killed by being immersed in strong vinegar, in which they are left for 12 hours closely covered up: should the weather be cool they may be left in the vinegar 2 or 3 hours longer. When removed therefrom, and pulled asunder, two transparent yellow green cords will be observed: this is the silkworm gut: the other portion of the entrails are of a dark-green colour. If the gut be soft, or break by stretching, that is an indication that the worm has been taken out of the vinegar too soon. When the gut is fit for drawing out, one end is to be dipped into the vinegar, and the other to be gently stretched to the required length, and it must be kept extended on a thin piece of board by inserting its extremities into slits in the end of the wood, or fastening them to pins, and in this state it is placed in the sun to dry.—*Tomlinson.*

(7621) SILK WORM.

Puttoo poochie, TAM.	Puttoo poorughoo, TEL.
Reshm ke keereh, DUK.	

These are the names of the common sort, but there is frequently met with in the southern parts of India, a large species of caterpillar, of a dirty, brownish, yellow color, which produces a very coarse kind of silk, or rather thread, and has, on this account, got from the weavers the name of "Nar puttoo pootchie," it is nearly three times as big as the common silk worm and its body is marked, not with seven, but eleven rings.—*Ainslie's Mat. Met. p.* 296.

(7622) SILPHIUM (Σίλφιον). Ancient authors mention this plant and its juice. Two kinds of this substance are described; one, from Cyrene, was probably yielded by *Thapsia Silphium* [LASER]; and the other was most likely assafœtida, which has been employed medicinally by Asiatics from very early times, though it has been known by this name in comparatively modern times. *Silphium* was however remarka.

ble for other properties, and hence has attracted the attention of modern travellers who have recently visited the countries where the *Silphium* is described as growing by the ancients. The army of Alexander, in crossing the mountain range which Arrian calls Caucasus (iii. 28, 10), and which is the same range that he afterwards mentions under the name of Paropamisus (v. 5, 3), met with the *Silphium*. Arrian says, on the authority of Aristobulus, "In this part of the Caucasus nothing grows except pines and *Silphium*, but the country was populous and fed many sheep and cattle, for the sheep are very fond of the *Silphium*. If a sheep should perceive the *Silphium* from a distance, it runs to it, and feeds on the flower, and digs up the root and eats that also. For this reason, in Cyrene, they drive the sheep as far as possible from the spots where the *Silphium* grows, and some even fence in such places to prevent the sheep from entering them if they should approach; for the *Silphium* is worth a good deal to the Cyrenæans." Burnes, in crossing the Hindu Koosh, and seeing both the men and cattle eating the young parts of the assafætida plant, supposed that it must be the *Silphium* of Arrian. But as this author describes the country where the *Silphium* grows as abounding in cattle, Dr. Royle had concluded that the *Prangos* of Mr. Moorcroft was the *Silphium* alluded to, and which is much fed on by sheep and cattle in the present day in Tibet, Mr. Vigne, when travelling in these regions, came to the same conclusion. It is probable therefore that both plants, being umbelliferous, and employed for the same purposes in nearly the same regions, may have contributed to form the accounts which are so brief in ancient authors. —*Eng. Cyc*

(7623) SILVER.

Fazzeh, ARAB.	Perak MAL.

Silver is one of the most anciently known of the metals, is found native and also combined with Sulphur in considerable quantities, also as a Chloride, and alloyed with other metals, especially Lead, Gold, Antimony, Arsenic, Copper. It is separated from its ores by the process of amalgamation. The Arabs are thought to have been the first to employ it in medicine. In its metallic state it is inert, but being little liable to alteration, or to be affected by reagents, it is much employed for surgical instruments and for vessels for chemical purposes.—*Royle.* Among the metallic ores of Southern India, holding the promise of being marketable, are a rich ore of galena or sulphuret of lead from Jungumrazpillay in the vicinity of Cuddapah. This ore is rich in silver, and is worked by the Natives on this account, but all the lead is wasted and the silver is obtained by a tedious, clumsy, and expensive process. Mr. H. L. Pattinson's new process for separating the metals by careful, slow-cooling and crystalization, is applicable to this ore. The re-examination of the first specimen of a Kurnool ore proved it to contain upwards of 1 per cent of silver, or 374 ounces in the ton, the quantity of lead and silver together being only 45 per cent which was occasioned by there being a considerable quantity of gangue disseminated through the portion examined. Another specimen, given by Colonel Cotton, and also said to be from Kurnool, was found to contain 175 oz. 3 dwts. in the ton. Dr. Scott some years ago examined a specimen of the Kurnool Galena and found it to be free of silver. But the re-examination of the specimens in 1857, revealed the fact that at least some portions are very rich in the precious metal and this accords with the recent researches of Malagah and Durochet who have found that when Sulphide of Silver is associated with the Sulphides of other metals, it is *always* unequally distributed. It would appear therefore from the above facts that it would be quite impossible to calculate, with any approach to accuracy, from the examination of any given specimen, what would be the average yield of silver in a silver lead mine, until it is actually worked for the separation of that metal. Considering however that nearly one half of the silver now in circulation in Great Britain is recovered from silver lead ores similar to the above, and seeing that it is found to be advantageous to separate the precious metal where it exists to the extent of only 6 ounces in the ton, it becomes evident that these ores must be of great value provided they can be found in sufficient quantity. From recent information obtained from Kurnool it would appear that the Galena there occurs abundantly in all probability; therefore it would prove to be highly remunerative to work this mine, both for the lead and silver contained in the ores.—*M. E. of* 1857.

Silver has been got, in trifling quantities, in upper India. The late Mr. W. Mainwaring found it in the Madura district in a native Sulphuret of Zinc (blende) Captain Arthur was the first who discovered this metal in Mysore, both in its native state (in thin plates adhering to some specimens of Gold crystallized in minute cubes) and as a muriate in an ore containing Sulphur and oxide of Iron.—*Ainslie.*

At the Madras Exhibition of 1857, a rich ore of Argentiferous Galena was exhibited from Martaban by Dr. Brandis, granular, or in minute crystals, with silver passing through it in thready

veins. This ore assayed by Dr. Scott, contains about 80 per cent of silver lead. The quantity of silver was found to vary in the portion examined from 70 to 300 ounces in the ton of ore. It is imposible therefore to say what its commercial value may be, unless an average sample were obtained, but if the ore exists in any quantity and of the same quality as that examined, it is a most valuable one, and would be well worth working by Pattenson's mode for separating the silver, as the process proves remunerative where only 7 ounces of silver can be obtained from a ton of metal.—*M. E. J. R.* This is probably the ore referred to by the Rev. Francis Mason, A. M. in his publication on the natural productions of Burmah, where, he says, the limestone of the Provinces probably contains a large quantity of lead: in the valley of the Salwen there is a rich vein of argentiferous galena, which is reported to appear on the surface. A specimen which Dr. Morton sent to England for analysis, was said to be a very valuable mineral, and destined to make a fortune for some one. Professor Mitchell in the certificate that he furnished Dr. Morton of the analysis, says, it contains Lead, Sulphur, Silver, Gold, (traces) Lime, Magnesia, Iron, Silica, and Carbonic Acid. It is a sulphuret of lead or galena. The quantity of lead and silver appears to be considerable, but there was not sufficient of the mineral to estimate either." The ore is seen in the limestone precisely as galena is found in the limestone of the Mississippi, one of the richest known deposits of lead in the world.—*Mason.* In a small hand specimen from Martaban the amount of silver was found to vary in different portions of it, the per centage of lead being about 75. In the first trial, the silver was found to amount to about 70 ounces to the ton of the ore; but in the second to not less than 300 ounces in the ton, or a little less than 1 per cent.—*M. E. J. R.* Mr. O'Riley had a specimen of an ore of silver, antimony, copper, and sulphur brought him, which produced thirty-five per cent of silver; and the Tavoy gold, it would appear, contains nearly ten per cent of the same metal.—*Mason.*

Silver is brought from Yennan near the borders of Cochin-China and the mines in that region must be both extensive and easily worked to afford such large quantities as have been exported during the last five years.—*Williams' Middle Kingdom, p.* 144. Gold is found in many parts of the Japanese Empire, sometimes it is obtained from its own ore, sometimes from the washings of the earth or sand and sometimes it is mixed with the copper. The quantity in the country is undoubtedly great. An old spanish writer of the seventeenth century tells us that in his day the palace of the Emperor at Yeddo, as well as many houses of the nobility were literally covered with plates of gold. In the beginning of the Dutch trade the annual export was £840,000 sterling and in the course of sixty years the amount sent out of the Kingdom through the Dutch alone was from twenty-five to fifty millions sterling. Silver mines are quite as numerous as those of gold. In one year the Protuguese, while they had the trade, exported in silver £587,500 sterling. Copper abounds throughout the whole Japanese group and some of it is said to be not surpassed by any in the world. The natives refine it and cast it into cylinders about a foot long and an inch thick. The coarser kinds they cast into round lumps or cakes. Quicksilver is said to be abundant but this, so far as we know, has never been an article of export. Lead also is found to be plentiful but like quicksilver it has not been sent out of the kingdom. Tin has also been discovered in small quantities, and of a quality so fine and white that it almost equals silver, but of the extent of this mineral little is known, as the Japanese do not attach much value to it, and therefore have not sought for it. Iron is found in three of the provinces, and probably exists in others. The Japanese know how to reduce the ore, and the metal they obtain is of superior quality, of which they make steel unsurpassed in excellency. "They have no want of coals in Japan," says Kœmpfer, "they being dug up in great quantities in the province of Sikusen and in most of the northern provinces." Dr. Siebold also speaks of coal as being in common use throughout the country, and on visiting one of the mines he saw enough to convince him that it was skilfully worked. For domestic purposes they convert the coal into coke. Viewed in the light of commercial intercourse between the two hemispheres, this coal is worth more than all the metallic deposits we have enumerated.—In a region so volcanic, sulphur is, as might be expected, an abundant mineral. In some places it lies in broad deep beds, and may be dug up and removed with as much ease as sand. A considerable revenue is derived by the government from sulphur.—*American Expedition to Japan, p.* 76. On the island of Banca there are silver-mines, but the Sultan has a great objection to their being worked: there are silver mines too in the Kingdom of Ava. We also know this valuable metal to be a product of Siam, from which country it is occasionly brought to India as well as from Manilla and Batavia.—*Ainslie.* Crawfurd however says that no veins of this metal have hitherto been discovered in any of the islands of the Malay or Philippine Archipelagos, many of which contain such abundant stores of iron, gold, tin and antimony. A small quantity of it, however, appears to be contained in all the gold of these countries. In Malay the name for silver is perak, and in Javanese salaka. Both are native words of which the origin has not been traced.—*Crawfurd Dict. page* 395.

Silver was well known to the ancients, and

is mentioned in the book of Job. It is the whitest of all the metals, and capable of receiving a lustre which is scarcely inferior to that of polished steel. In its polished state it reflects more light and heat than any other metal, so that it has a very low radiating power for heat, and hence a silver vessel retains the heat of the liquid contained in it longer than a vessel of any other metal. The preference given to a silver pot for making tea is founded on correct observation: a black earthen ware vessel is such a powerful radiator of heat, that a hot liquid contained in it rapidly declines in temperature, and if used for making tea the temperature of the boiling water soon falls below the point required for making the infusion. Silver ranks next to gold in ductility and malleability. Its density is 10·47: it is harder than gold and softer than copper, and, when pure, it is so soft as to be cut by a knife: the addition of a small quantity of copper increases its hardness: it fuses at a full-red heat, corresponding to 1,873° Fahr. Exposed to the heat of a blast furnace, silver throws off metallic vapours, and when fused between the charcoal electrodes of a powerful voltaic battery it is readily volatilized. There is a large demand for silver not only for the purposes of coinage, but also for services of plate, for which it is admirably adapted, inasmuch as it is not attacked in the slightest degree by any of the substances used for food. The large demand for the metal thus occasioned is met by its comparative abundance in the native state or alloyed with various other metals; it is also found mineralized by the non-metallic elements, and also in combination with certain acids. It is also obtained in large quantities from lead ores, as noticed under LEAD. One of the richest and most abundant ores of Chili is the *chloride*, where it is often accompanied by native silver. A large proportion of the silver of commerce is extracted from ores which are too poor to allow of their being smelted or fused, even supposing fuel were abundant in the neighbourhood of the mines, which is not the case. Recourse is therefore had to the process of *amalgamation* founded on the ready solubility of silver and many other metals in metallic mercury. The Saxon process as adopted at Freyberg differs somewhat from the American process.—*Tomlinson.*

Silver, has been well known and highly valued from the remotest period, a circumstance which is readily explained by the fact of its occurring frequently native, and possessing great lustre and fitness for immediate use without being subjected to any metallurgic process. Native Silver occurs crystallised, arborescent, or dendritic, capillary, reticulated, granular, and massive. The primary form of the crystal is a cube. It has no cleavage. Fracture hackly. Colour white, but externally often blackish, owing probably to the presence of a little sulphur. Hardness 2.5 to 3. Lustre metallic. Color pure white, except when tarnished. Streak shining. Opaque. Specific gravity 10.47. Malleable, but commonly less so than pure silver, probably owing to an admixture of other metals. Soluble in nitric acid, and the solution colourless when pure, but blue, if copper be present; and if antimony, a white substance; and if gold, a black one remains undissolved. Fuses into malleable globules before the blow-pipe. Native Silver is met with in most parts of the western world; in the British Isles, Germany, Hungary, in the north of Europe, but especially, and in largest quantity, in Mexico and South America. Silver occurs in mixture or combination with other metals. The ores from which the silver of commerce is mostly obtained are the Vitreous Silver, Brittle, or Black Silver-Ore, Red Silver-Ore, and Horn Silver, in addition to Native Silver. Besides these, silver is obtained in large quantities from galena (lead-ore), and from different ores of copper; and some galenas are so rich in silver that the lead is neglected for the more precious metal. This metal occurs in rocks of various ages, in gneiss, and allied rocks, in porphyry, trap, sandstone, limestone, and shales; and the sandstone, and shales may be as recent as the middle secondary, as is the case in Prussia. The silver-ores are associated often with ores of lead, zinc, copper, cobalt and antimony, and the usual gangue is calc spar or quartz, with frequently flour spar, pearl spar, or heavy spar. The Silver of South America is derived principally from the Horn Silver and Brittle Silver-Ores, including Arseniuretted Silver-Ore, Vitreous Silver-Ore, and Native Silver. Those of Mexico are of nearly the same character. Besides, there are earthy ores called Colorados, and in Peru, Pacos, which are mostly earthy oxides of iron, with a little disseminated silver; they are found near the surface, where the rock has undergone partial decomposition. The sulphurets of lead, iron, and copper, of the mining regions, generally contain silver, and are also worked. (Dana). The principal mines of silver in Europe are those of Spain, of Konigsberg in Norway, of Saxony, the Hartz, Austria, and Russia. In England, argentiferous galena is worked for its silver. Forty thousand tons of this ore were reduced in 1837, which contained upon an average about six ounces of silver in a ton of lead. The annual product of the several countries of Europe is thus estimated by Dana in his 'Manual of Mineralogy:'—

	Pounds Troy.
British Isles,	7,500
France,	4,150
Austria,	63,000
Sweden and Norway,	13,000
Spain,	130,000
Saxony, the Hartz, and other parts of Germany,	78,500
Belgium	440
Piedmont, Switzerland, and Saxony	1,560

making in all 298,150 troy pounds, or about 4,500,000 dollars annually. With the sum from Russia, about 730,000 dollars, it becomes 5,230,000 dollars a year. This is small compared with the amount from America, which at the beginning of the present century equalled 2,100,000 pounds, or 31½ millions of dollars, nearly six times the above sum; and it is probable that these mines will again yield this amount when properly worked. The whole sum from Russia, Europe, and America, makes nearly 2,000,000 pounds avoirdupois.—*Eng. Cyc.*

(7624) SIMARUBACEÆ, *Quassiads*, a natural order of Plants belonging to the Gynobasic group of Polypetalous Exogens. The plants of this order are trees or shrubs, with alternate exstipulate usually compound leaves, and mostly without dots. The flowers are whitish-green or purple, on axillary or terminal peduncles, hermaphrodite, or occasionally unisexal; the calyx is 4-5-parted; petals 4-5, twisted in æstivation; stamens twice as many as the petals, arising from the back of an hypogynous scale; ovary 4-5-lobed; style simple; stigma 4-5-lobed. Fruit a drupe. Seeds pendulous, exalbuminous, with a superior short radicle drawn back within thick cotyledons. With one exception, they are all natives of Africa, India, and tropical America.—*Eng. Cyc.*

(7625) SIMIADÆ, the name of a Quadrumanous family of Mammalian Animals. It embraces the most highly-developed forms of the Monkey, and the relations of this family might be more or less given under the following articles: —APE; ATELES; BABOON; CHEIROPODA CHIMPANZEE; HYLOBATES; LAGOTHRIX; MACACUS; MYCETES, NASALIS; ORANG-OUTAN; QUADRUMANA; SAKIS; SAPAJOUS; and SEMNOPITHECUS. These animals were known at a very early period. The Kophim of the Scriptures (1 Kings, x. 22; 2 Chron., ix. 21), the Ceph of the Ethiopians, the Keibi and Kubbi of the Persians, the Κῆβοι of the Greeks, and Cephi of the Romans, were clearly Apes. They are to be traced in some of the earliest paintings of the Egyptians. (Rosellini, &c.) The Cephi exhibited by Pompey, (Pliny, 'Hist. Nat.,' viii. 19), as well as those shown by Cæsar, appear to have been Ethiopian apes; and in the Greek name inscribed near the Quadrumanous animals in the Prænestine pavement, the oriental origin of the word is apparent. It is remarkable that the name *Cebus* [SAPAJOUS] is applied by modern zoologists to a genus of monkeys which could not have been known to the ancients; for the *Cebi* of our present catalogues are exclusively American. The following is a definition of the family *Simiadæ*, which embraces the animals to which the term Ape is most properly applied. They are all of them inhabitants of the old world:—The nostrils are divided by a narrow septum; they possess opposable thumbs on their fore and hind feet; the callosites on the rump are generally naked. Some of the species only are furnished with cheek-pouches. They usually possess a tail. The dental formula is as follows:—

$$\text{Incisors } \frac{4}{4}\ \text{Canines, } \frac{1-1}{1-1};\ \text{Premolar, } \frac{2-2}{2-2};\ \text{Molars, } \frac{3-3}{3-3};\ = 32.$$

The following definition of the second family of the *Quadrumana*, the *Cebidæ*, will afford the means of contrasting the two families:—The *Cebidæ* are natives of America. The nostrils are separated by a broad septum; the thumbs are sometimes absent on the fore feet; callosities and cheek-pouches absent; the tail is always present, and sometimes prehensile. In the list of the specimens of *Mammalia* published by Dr. J. E. Gray, we find almost a complete representation of the Asiatic forms of this family. They are as follows:—

(7626) Chimpanzee (*Troglodytes niger*, Geoff; *Homo Troglodytos*, Linn). West Africa.

(7627) Orang-Outan, or Pongo (*Simia Satyrus*, Linn.; *S. Wurmbii, Kuhl; S Agrias*, Schreb.) Borneo. [ORANG-OUTAN.]

(7628) Siamang (*Siamanga Syndactyla*; *Simia Syndactyla*, Raffles, Horsf.) Java.

(7629) Hoolock (*Hylobates Hoolock*, Martin; *Simia Hoolock*, Harlan). [HYLOBATES.]

(7630) Oungka (*H. agilis*, F. Cuv.; *Simia Lar.*, Vigors and Horsfield; *Pithecus agilis*, Desm.). Himalaya and Malacca.

(7631) Gibbon (*H. Lar*; *Homo Lar*, Linn.; *S. longimana*, Schreb.). Malacca.

(7632) Silvery Gibbon, or Wou-Wou (*H. leuciscus* Kuhl; *Simia leucisca*, Schreb.). Malacca.

(7633) Kalasie (*Presbytes rubicunda*) Borneo.

(7634) Simpal (*P. melalophos*; *Simia melalophos*, Raffles). Sumatra.

(7635) Tianac (*P. flavimana*; *Semnopithecus flavimanus*, I. Geoff.). Sumatra.

(7636) Rufous Presbytis (*P. nobilis*, Gray *Semnopithecus melalophos*, Desm.). Himalaya.

(7637) Lutung (*P. Pyrrhus*). Java.

(7638) Chingkau (*P. cristata*; *Simia cristata*, Raffles) Java and Sumatra.

(7639) Dusky Presbytis (*P. obscura*). Singapoor.

(7640) Negro Presbytis (*P. maura; Simia maura*, Schreb. China.

(7641) Hooded Presbytis (*P. Jhonii; Simia Jhonii*, Fischer). India, Madras.

(7642) Hoonuman (*P. entellus*). Bombay and Nepaul.

(7643) Nestor (*P. cephalopterus; Cercopithicus cephalopterus*, Zimm.). Ceylon.

(7644) Zati, or Capped Macaque (*Macacus radiatus*, Desm.) India.

(7645) Munga, or Bonnet-Macaque (*M. Sinicus*, Desm.; *Simia Sinica*, Linn.) India.

(7646) Bruh (*M. nemestrinus*, Desm.; *Simia nemestrina*, Linnæus). Sumatra.

(7647) Macaque (*M. cynomolgus*, Desm.; *Simia cynomolgos*, Linn.) India, Sumatra.

(7648) Rhesus (*M. Rhesus*, Desm.; *Simia Rhesus*, Audeb.) India, Bengal.

(7649) Oinops (*M. Oinops*). Nepaul.

(7650) Brilliant Macaque (*M. speciosus*, F. Cuv.) Japan.

(7651) Black Macaque (*M. niger*, Bennett; *Cynocephalus niger*, Desm.). Philippines.

(7652) Wanderoo (*S. veter*; *Simia Silenus*, and *S. Veter*, Linnæus). Ceylon, China, India.

(7653) Gelada (*Gelada Ruppellii*). Abyssinia.

(7654) Tartarin (*Cynocephalus Hamadryas*, Latr: *Simia Hamadryas*, Linn.) Abyssinia.

The following forms of *Simiadæ* and *Cebidæ* were existing in the Gardens of the Zoological Society, Regent's Park, between the years 1847 and 1852 :—

Simiadæ.

Simia Satyrus, Hylobates Hoolook, Semnopithecus Gulettus, Cercopithecus nictitans, C. petaurista, C. melanogenys, C. cephus, C. albopilaris, C. Campbellii, C. Pluto, C. Mona, C. Pygerythrus, C. Sabæus, C. cynosurus, C. callithricus, C. Talaponi, C. niger, Cercocebus fuliginosus, C. Æthiops, Macacus sinicus, M. pileatus, M. cynomolgus, M. erythræus, M. nemæstrinus, M. Silenus, M. niger, Inuus sylvanus, Cynocephalus Hamadryas, C. Sphinx, C. Babouin, C. Porcarius, C. leucophæus, C. Mormon.

Cebidæ.

Ateles Chamek, A. paniscus, A. ater, A. Beelzebuth, A. marginatus; Pithecia chiropotes; Lagothrix Humboldtii; Brachyurus Ouakari; Saimiri sciureus; Callithrix torquatus; Nyctipithecus trivirgatus; Cebus apella, C. capucinus, C. cirrifer, C. xanthosternum, C. hypoleucus; Hapale Jacchus, H. aurita, H. penicillata, H. (Midas) Œdipus, H. (Midas) rufimanus, H. (Midas) Tamarin.

Fossil Simiadæ.—Remains of *Simiadæ* have been discovered and described from the tertiary formations of India, France, England, and Brazil. These fossils are illustrative of four of the existing types of quadrumanous or rather Simious forms. Thus we have *Semnopithecus* from India; *Hylobates* from the south of France; *Macacus* from Suffolk; and *Callithrix*, peculiar to America, found in Brazil. Nor is it unworthy of remark, that we here have evidence that so high a quadrumanous form as the Gibbon, a genus in which the skull is even more approximated to that of man than it is in the Chimpanzee, was living upon our globe with the Palæothere, Elephants, and other Pachyderms. We say that the skull of the Gibbon comes nearest to that of man, because, though the cranium of the young Chimpanzee approaches that of the human subject, it is far removed from it when the permanent teeth are developed. Teeth of *Macacus*, are the only remains of the *Quadrumana* which have been found in Britain. In other countries larger remains have been found. Thus, in 1836, Lieutenants Baker and Durand discovered, in the Sub-Himalayan Hills, near the Sutlej, an almost entire right superior maxillary bone, containing the five molar teeth and part of the canine. The strata in which this fossil was found was tertiary, and consisted of a mixed calcareous sandstone and clay. In the year following, Colonel Cautley and Dr. Falconer discovered in the same formation a considerable portion of the lower jaw, with all the molars of the right side, and a part of the teeth of the left side, together with two middle incisors and the right canine. These remains belonged to a species of *Semnopithecus*, which must have existed with the *Sivatherium* and *Hippopotamus*, whose remains were found in the same formation.—*Eng. Cyc.*

(7655) SIPHONOSTOMATA, M. De Blainville's name for his first family of Siphonobranchiate *Mollusca*. The forms comprised under this family are principally to be found under the extensive genus *Murex* of Linnæus. It is sometimes applied to several families forming a section of Prosobranchiated *Mollusca*. In Woodward's 'Manual' the following families are included :—

1. *Strombidæ.* [STROMBIDÆ.]
2. *Buccinidæ.* [BUCCINUM.]
3. *Conidæ.* [CONIDÆ.]
4. *Volutidæ.* [VOLUTIDÆ.]
5. *Cypræidæ.* [CYPRÆIDÆ.]

All the known animals belonging to it are carnivorous and marine, and all are furnished with a horny operculum. The *Siphonostomata* are thus subdivided by M. De Blainville :—

Pleurotoma (Lam.)

(7656) *P. Babylonia.* The shell fusiform-turreted, transversely carinated and belted, white, with black-spotted belts, the spots quadrate; whorls convex; tube or canal rather long. It is found in the East Indian Seas and the Moluccas.

British Islands and Greenland	17
Mediterranean	19
Africa	15
Red Sea and India	6
China	90
Australia	15
Western America	52
West Indies and Brazil	20

Fusus (Lam.).

(7657) *F. Colus* (*Murex Colus* Linn.) Shell fusiform, narrow, transversely furrowed, white, the apex and base rufous; whorls convex, nodulously carinated in the middle; canal long and slender; the lip sulcated within, and denticulate on the margin. It is a native of the East Indian Ocean.

Pyrula (Lam.)

(7658) *P. carnaria* (*P. Vespertilio*, Lam.; *Fusus carnarues*, Mart.; *Murex Vespertilio*, Gm.) Shell subpyriform, thick, ponderous, muricated anteriorly, of a rufous-bay colour; the last whorl crowned above with compressed tubercles; spire rather prominent; the sutures simple; canal sulcated and subumbilicated. It is a native of the Indian Ocean.

(7659) *P. Spirillus*. Shell ventricose anteriorly the canal very long delicately striated transversely, white, spotted with saffron-colour; body-whorl abbreviated; carinated in the middle, flattened above, tuberculated below the middle; spire very much depressed, its apex mamilliferous. It is a native of the East Indian Ocean and the coasts of Tranquebar.

(7660) *P. ficus*. Shell fig-shaped, delicately decussated, cœrulescent-gray; sprinkled with variegated bay or violet spots; transverse striæ the largest and most crowded; the spire short, convex, mucronated at the centre; mouth cœrulescent-violaceous generally. It is a native of the Indian Ocean and the Moluccas.

Pyrulæ have been found on mud, sandy muds, and sand, at depths ranging from the surface to nine fathoms. There are 59 recent species and 39 fossil. The recent are found in the West Indies, Ceylon, Australia, China, and West America. The fossil are found in the Neocomian beds of Europe, India, and Chile.

Fasciolaria (Lam.).

(7661) *F. Trapezium*. Shell fusiform, ventricose, tuberculiferous, rather smooth, white or rufescent, girt with rufous lines; the tubercles conical, subcompressed, and in a single series in the middle of the whorls: columella reddish-yellow; outer lip elegantly striated within, the striæ red. It is found in the East Indian Ocean.

(7662) *F. filamentosa*. Shell elongated, fusiform, turreted, transversely sulcated, white, painted with longitudinal orange-red stripes; middle of the whorls subangulated, and the whorls themselves crowned with short and compressed tubercles; the canal rather long; the outer lip striated within. It is found in the East Indian seas.

Fasciolariæ have been found on muddy bottoms, at depths ranging from the surface to seven fathoms. There are 11 recent and 28 fossil species. The former are found in the West Indies, Mediterranean, West Africa, India, Australia, the South Pacific, and Western America. The latter are found in the Upper Chalk.

Turbinella (Lam).

(7663) *Turbinella Rapa*. Shell subfusiform, ventricose in the middle, thick, very ponderous, unarmed, white; the whorls above covering the base of the preceding one; canal rather short; columella subquadriplicated. It is found in the East Indian Ocean.

(7664) *T. Scolymus*. Shell subfusiform, ventricose in the middle, tuberculated, pale yellow; spire conical, tuberculato-nodose; the last whorl crowned above with great tubercles; canal transversely sulcated; the columella orange-coloured and three-plaited. It is a native of the East Indian Ocean.

Turbinellæ have been found on bottoms of sandy mud, at depths varying from the surface to 18 fathoms. There are 70 recent species, chiefly tropical, and 20 fossil, from the Miocene Tertiary beds.

Triton (Lam.)

(7665) *Triton variegatus*, the Marine Trumpet, or Triton's Shell. Shell elongated conical, trumpet-shaped, ventricose below, grit with very obtuse smooth ribs, white, elegantly variegated with red and bay; the sutures crisped at the margin; the aperture red; the columella wrinkled with white and with a single plait above; the edge of the outer lip spotted with black, the spots bidentated with white. It is a native of the seas of the West Indies and the Asiatic seas, especially those of the torrid zone.

(7666) *Triton Lotorium*. Shell fusiform turreted, distorted below, very much tuberculated, transversely rugous, and striated, rufous; the whorls above angulate-tuberculated; canal tortuous, the extremity recurved; the aperture trigono-elongated and white; the outer lip toothed within. It is a native of the East Indian Ocean.

(7667) *Triton Anus*, the Grimace. Shell ovate, ventricose-gibbous, distorted, flattened beneath; nodulous above, subcancellated, white, spotted with rufous; the aperture narrowed, sinuous, irregular, ringent; the lip very much toothed; the canal short and recurved. It is found in the East Indian seas. Tritons have been found on various bottoms at depths ranging from the surface to 30 fathoms.

(7668) *Ranella* (Lam.).—Shell oval or oblong, depressed, having only two varices situated latterally; aperture oval; canal short, and a sinous at the union of the two lips, backwards.

(Genus *Bufo*, De Montfort).

(7669) *R. granulata*, a native of the East Indian Ocean.

(7670) *R. foliata*, found in the vicinity of Mauritius.

Ranellæ have been taken on different bottoms at depths varying from the surface to 20 fathoms.

Fifty recent and 23 fossil species have been described.

Murex. (Linn.).

(7671) *Murex Tribulus*, Linn. (*Murex tenuispina*, Lam).—Shell ventricose anteriorly, the tube very long, elegantly spired throughout its length, the spires set in triple order, each row at regular intervals, grayish or purplish gray, the spires very long, thin, rather closely set and somewhat hooked ; body of the shell transversely sulcated and striated ; the spire prominent. It is a native of the Indian Ocean and the Moluccas. This is the Venus's Comb of collectors, and when perfect is a most delicate and striking shell.

(7672) *M. haustellum* (Snipe's or Woodcock's Head of collectors) .Shell anteriorly ventricose, naked, scarcely armed, fulvous inclining to red, lineated with bay ; body of the shell rounded and furnished with three or more ribs between the varices ; the tube very long and slender ; the spire short ; mouth rounded, red. It is a native of the East Indian Ocean and the Moluccas.

(7673) *M. acanthopterus.* Shell oblong, fusiform, trialated, transversely sulcated and striated, white ; the alæ membranaceous ; whorls angulated ; aperture ovate rounded. It is a native of the East Indian Seas.

(7674) *M. adustus.* It is a native of the East Indian Ocean.

(7675) SINAPIS, the name of a genus of Plants belonging to the natural order *Cruciferæ*, or *Brassicaceæ*. All the species are known by the name of Mustard, a word derived from *Mustum ardens*, in allusion to their hot and biting character. The genus is known by its siliquose fruit, which is rather terete, with nerved valves ; small short acute style ; sub-globose seeds disposed in one row in each cell, and spreading calyx. The leaves are of various forms, lyrate or deeply toothed ; the flowers yellow, arranged on terminal bractless racemes ; they are chiefly natives of the temperate parts of both hemispheres of the Old World. Between 40 and 50 species of this genus are enumerated. Of these, two species are well known and much cultivated in this country, *S. nigra* and *S. alba*, the Black and White Mustard.—*Eng. Cyc.* Five or six species of Sinapis are cultivated in all parts of India, for the sake of the valuable oil they yield, those most frequently seen are *S. glauca*, *toria* and *racemosa*.—*M. E. J. R.*

(7676) SINAPIS ALBA. The seeds of the "sinapis alba" yield by expression 36 per cent of a bright yellow, pleasant tasted, edible oil, having a strong smell, and slight taste of mustard. The seeds of "sinapis nigra," yield only 28 per cent of an oil in all respects similar to the above. The average price of mustard seed in eighteen large stations, in all parts of the Madras Presidency, for the Quarter ending 31st October 1854, was Rs. 1 2 8 per maund of 25lbs., the maximum being Rs. 1 11 6 at Cannanore and the minimum As. 15 5 at Nagpore. In Vizagapatam it costs Rs. 2 8 per Sicca garee. The oil is not exported from Madras, but the seeds have been shipped as follows :

In the years	1847-48	Cwt.	5,828
,,	1848-49	,,	6,767
,,	1849-50	,,	9,435
,,	1850-51	,,	9,909
,,	1851-52	,,	3,636
,,	1852-53	,,	16,075

—*M. E. J. R.*

The Mustard plant is officinal on account of its seeds, or rather of the flour of these seeds, so well known as a condiment by the name of Mustard. But Dr. Pereira learnt that the best flour of Mustard is prepared by crushing the seeds of both Black and White Mustard between rollers, and then pounding them in mortars, when they are twice sifted to yield *pure flour of Mustard.* Dr. Christison's information confirms that of Dr. Pereira, that common flour of Mustard is adulterated, partly on account of the pungency of Black Mustard seed. "Two bushels of black, and three of white seed yield, when ground, 145 pounds of flour ; which, to diminish the pungency and improve the colour, is mixed with 56 pounds of wheat flour and two pounds of turmeric ; and the acrimony is retored without the pungency, by the addition of a pound of (capsicum) chilly pods, and half a pound of ginger." (*c*) Dr. Thomson says he could detect no turmeric, nor cayenne pepper in the specimen which he examined. The *pure flour* of Mustard ought alone to be used officinally. Though Black and White Mustard have both been minutely examined by several chemists, they still require further investigation. The former contains a Fixed Oil, Gummy matter, Sugar, a Colouring and a Peculiar green matter, a Fatty pearly matter ; *Myronic acid* in combination with Potash, or Myronate of Potash (the Sulpho-Sinapisin of Henry and Garot) *Myrosyne*, *Sinapisin*, and some salts.—*Royle.*

The oil.

Mustard Oil, ENG.	Kadaghoo yennai, TAM.
Avaloo and Sursava noona, TEL.	Raee ka tael, HIND.
Sarshapatailum, SANS.	Rai ka tael, GUZ.

This valuable oil, although seldom sold in the Market, being only made when required, is used in most parts of India in cookery, and is considered superior to all other oils for anointing the body, which it is supposed to invigorate. In medicine, it is sometimes given internally, but is more frequently applied as a rubifacient.—*M. E. J. R.* Common Mustard consists of the flour of the seeds of the Black Mustard, though generally mixed with that procured from the seeds of the White Mustard, or Sinapis alba, and deprived of fixed oil by expression. Both species have been

long used in medicine, being the *vara* of Hippocrates, and the Sinapi of the Romans.—*Royle.*

The botanical description *of Sinapis alba, or* "White Mustard." would be Siliques hispid, spreading, rather narrower than the ensiform beak; leaves lyrate, smoothish; stem smooth. It is a native of Great Britain and most countries in the south of Europe. It is frequently cultivated, and when young is eaten as a salad. —*Eng. Cyc.*

(7677) SINAPIS CHINENSIS. MUSTARD SEED. Lin.

Kadaghoo, TAM.	Sasavee, MALAY.
Rai, GUZ.	Tukhm-i sipeedan, PERS.
Rains, DUK.	
Rai, HIND.	Rajaca, SANS.
Khirdull, ARAB.	Avaloo, TEL.

Ainslie's Mat Med. p. 264.

(7678) SINAPIS DICHOTOMA, OR MUSTARD.

Moung-ngyeen, BURM.

This is cultivated in small quantity in the Tounghoo district.—*McClelland.*

(7679) SINAPIS NIGRA, Black Mustard, is known by its smooth, even, somewhat tetragonal siliques closely pressed to the peduncle; lyrate lower leaves, and lanceolate upper leaves. It is found in cultivated fields, waste grounds, and roadsides throughout Europe. The black Mustard is indigenous in almost every part of Europe. The root is thick and fleshy, the stem about 2 to 3 or 4 feet high, hispid below, with smooth round branches above. Lower leaves large, rough, lyrate, variously lobed and toothed; upper ones narrow, lanceolate, smooth, dependent. Calyx yellowish, equal at base, spreading. Petals obovate, yellow, spreading. Silique small, erect, or placed close to the stem, obtusely quadrangular, nearly even and smooth, tipped by a short quadrangular style, but without the proper, often seed-bearing beak of the genus; the valves convex, with one straight dorsal nerve, and a few lateral anastomosing veins. Seeds numerous, in a single row, small, round, blackish brown. Fig. 41.—E. B. t. 969.

(7680) SINAPIS TRILOCULARIS. MUSTARD.

Rai, DUK.

(7681) SINGHARA. This is the spinous fruit of Trapa bispinosa &c. The plant furnishing this important article of food appears to have been extirpated from the tanks of southern India, while it has been still preserved in the Mahratta Country and Deccan.—*M. E. J. R.* There are more than one species which produce the Singhara or Water Nuts. The large seeds of *Trapa bicornis*, a native of China, and of *T. bispinosa* and *natans*, species indigenous to India, are sweet and eatable, and the aquatic plants which furnish them are hence an extensive article of cultivation. In Cashmere and other parts of the East they are common food, and known under the name of Singhara nuts. In Cashmere the government obtains from these nuts £12,000 of annual revenue. Mr. Moorcroft mentions that Runjeet Sing derived nearly the same sum. From 96,000 to 128,000 loads of this nut are yielded annually by the lake of Ooller alone. The nut abounds in fecula. In China the kernel is used as an article of food, being roasted or boiled like the potato. The seeds of various species of *Nelumbium*, natives of the East Indies, Jamaica, and the United States, also form articles of food. The fruit of *N. speciosum* is supposed to be the Egyptian bean of Pythagoras. The petioles and peduncles contain numerous spiral vessels, which have been used for wicks of candles. The fruit of *Willughbeia edulis*, a native of the East, as its name implies, is eatable. The kernel of the mango can be reduced to an excellent flour for making bread.—*Simmonds.*

(7682) SIPHOCAMPYLOS. *Lobeliaceæ.*—These are small pretty shrubs growing well in a light sandy soil, and are propagated by seed and cuttings.—*Riddell.*

(7683) SIPHONANTHUS FRAGRANS.

Hatti-kana, DUK.

Double variety. A native of China.—*Riddell.*

(7684) SIPHONANTHUS INDICA. *Verbenaceæ.*

Burungee, DUK.

A tall, erect growing, suffruticose plant, with linear leaves; flowers white or cream coloured, with long tubes.—*Riddell.*

(7685) SIPHONIA, a genus of Plants belonging to the natural order *Euphorbiaceæ*, consisting of two species, but one may be only a variety of the other. This is celebrated as being the tree which yields the large quantities of caoutchouc, called cahuchu by the native Americans, annually imported from Para in South America.—*Eng. Cyc.*

(7686) SIPHONIA ELASTICA is a tree 50 to 60 feet in height, common in the forests of Guiana and Brazil, and which has been introduced into the West Indies. Condamine frequently mentions it in his voyage down the Amazon. Caoutchouc is the milky juice of the plant, which exudes on incisions being made and solidifies on exposuore to the air. [INDIA RUBBER.]—*Eng. Cyc.*

(7687) SISON, a genus of Plants belonging to the natural order *Umbelliferæ*. It possesses the following characters:—calyx obsolete; petals broadly obcordate, deeply notched, and curved with an inflexed point; styles very short; fruit ovate, laterally compressed; carpels with five filiform equal ridges, of which the lateral ones are marginal; interstices with single short club-shaped vittæ; seed gibbous, convex, plane in

front; universal and partial involucre of few leaves.—*Eng. Cyc.*

(7688) SISSOO, (Dalbergia Sissoo,) is one of the most valuable of the timber-trees of India, and with the Saul, is more extensively employed than any other in north-west India. The ship-builders in Bengal select it for their crooked timbers and knees; it is remarkably strong, its colour is a light greyish brown, with darker coloured veins. "In structure it somewhat resembles the finer species of teak, but it is tougher and more elastic." There are two kinds used respectively in Bengal and Bombay, the latter is much darker in colour. The Indian black rose-wood, (Dalbergia latifolia,) is a superior species of Sissoo, from the Malabar-coast.—*Holt.*

(7689) SITANUK. One valve of a muscle shell, with the dried fish attached. The punsaris call it "the small head of a sea animal:" used in Ajmere as an aphrodisiac, and also said to cure the cynanche of children: comes from Bombay via Pali: one seer costs two rupees.—*Genl. Med. Top. p.* 132.

(7690) SIVATHERIUM (from Siva, an Indian deity), a genus of extinct animals belonging to the family *Elephantidæ*. The remains of species of this remarkable genus were found by Dr. Falconer and Colonel Cautley in the valley of Mackanda, in the Sewalik Hills of the Himalaya. Two species of this genus, *S. giganteum* and *S. Perimense*, have been described. A cranium, lower jaw and teeth, and bones of the extremities of *S. giganteum* are now in the British Museum. The skull of this animal is nearly as long as that of the Elephant, the neck was shorter and stronger than in the Giraffe. The posterior portion of the skull is greatly developed, and formed of cellular cavities, as in the Elephant. "The face is short, and the nasal bones are remarkable for the manner in which they are prolonged into a pointed arch above the external nostrils, indicating a trunk, or proboscis. The very inclined direction of the front of the face in relation to the triturating surface of the teeth imparts a physiognomy altogether peculiar. Two horns arise from the brow between the orbits, and diverge from each other, and it is probably that the posterior protuberances of the forehead also supported a pair of short massive horns." (Mantell.) When living, the Sivatherium must have resembled an immense Gnu, or Antelope, with a short thick head surmounted with two pairs of horns. The front pair of these horns were small, whilst those behind were probably palmated. The eyes were small, and it had a nasal proboscis, an organ unknown amongst the *Ruminantia*. (Mantell, *Petrefactions and their Teachings*; *Journal of the Asiatic Society*.).—*Eng. Cyc.*

(7691) SIZE.

Sirrus. Guz.; Sirisht, Hind. Glue.

A gelatinous substance, obtained from parchment-shavings, fish skin, and several animal membranes. It is less adhesive than glue, and is used by book-binders, paper-hangers, and painters. (*Waterston.*)—*Faulkner.*

(7692) SKIMMIA LAUREALA. This plant has been lately introduced into English gardens, from the northwest Himalaya, and is greatly admired for its aromatic, evergreen foliage, and clusters of scarlet berries. It is a curious fact, that this plant never bears scarlet berries in Sikkim, apparently owing to the want of sun; the fruit ripens, but is of a greenish-red or purplish colour.—*Hooker, Him. Jour. Vol.* 1, *p.* 187.

(7693) SKIMMIA REEVESIANA. On the same stage, Fortune says, with this Azalea I observed a fine new shrub, which I mistook for a holly. It turned out to be a species of *Skimmia*, and I observed that Dr. Lindley has described it as *Skimmia japonica*. It is however quite a different plant from that known by the name in the gardens of England, and I propose to call it *Skimmia Reevesiana*. —*Fortune's Tea Districts, page* 329.

(7694) SKINS.

Peaux, Fr.	Pelli, It.
Felle, Ger.	Churm, Pers.
Chamro, Guz.	Pelles, Port.
Chumra, Hind.	Pieles, Sp.

This term is applied in commercial language to the skins of those animals, as calves, deer, goats, lambs, &c. which, when prepared, are used in the lighter works of book binding, the manufacture of gloves, parchment, &c; while the term hides, is applied to the skins of the ox, horse, &c., which, when tanned, are used in the manufacture of shoes, harness, &c. (*McCulloch.*) Salted and tanned hides, and also sheep and goat skins, are exported from Bombay to London and Liverpool.—*Faulkner.*

(7695) SLATE (Roof).

Ardoise, Fr.	Lavagna, Lastra, It.
Schiefer, Ger.	Pizarra. Sp.

A laminated stony substance, of which there are many kinds; though the only one of commercial importance is *clay slate*, employed for roofing. The principal slate quarries in Britain, are [illegible] Wales, Cumberland, and Scotland.—*Faulkner.*

(7696) SLIPPER PLANT. Euphorbia Tithymaloides.

(7697) SMALTE.

Smalte Dut.	Schmalz, Ger.
Smalt, Fr.	Lasor, Rus.
Smalto azzurro, Smaltino, It.	Esmalte. Azul-azur, Sp.

An oxide of cobalt, melted with siliceous earth and potash. It is sort of glass, of a beautiful deep blue colour; and being ground very fine, is known by the name of azure or powder blue. It is in great demand for the painting of earthenware, in the colouring of paper, and for other

arposes in the arts. Smalt is principally manuctured in Germany and Norway.—*Faulkner.* he Chinese use it for painting on porcelain and lazed copper vessels; the consumption, which as never very great, has fallen off, and the price eclined the last few years.—*Morrison.*

(7698) SMILACEÆ, *Sarsaparillas*, a small atural order of Plants belonging to Lindley's ass of Dictyogens. There has been much difrence of opinion amongst botanists with regard the position of *Smilax* in the natural system, s well as the number of genera that ought to be dmitted into the order *Smilaceæ*. Lindley has laced two genera, *Smilax* and *Ripogonum*, in his order, which possess the following characrs: — Flowers hermaphrodite or dioecious; cax and corolla confounded, inferior 6-parted; tamens 6, inserted into the perianth near the ase, seldom hypogynous; ovary 3-celled, the ells, 1- or many-seeded; style usually trifid; tigmas 3; fruit a roundish berry; albumen beween fleshy and cartilaginous; embryo usually istant from the hilum. They are mostly herbaceous plants, with a woody stem, and a tendency to climb. Their leaves are reticulated. his last character separates the order from *Liiaceæ* and its allied orders, with which it otherise closely agrees. *Smilax* is found in most arts of the world, especially in Asia and merica. [SMILAX].—*Eng. Cyc.*

(7699) SMILACINA, is a potherb growng in Thibet, North of *Kinchinjunga*, to which Dr Hooker was afterwards more indebted than uy. This beautiful *plant*, grows from two to five eet high, and has plaited leaves and crowded paicles of white bell-shaped flowers, like those of s ally the lily of the valley, which it also resembles in its mucilaginous properties. It is called 'Choklibi" and its young flower-heads, sheathed in tender green leaves, form an excellent vegetable.—*Hooker, Him Jour. Vol.* II. *page* 47.

(7700) SMILAX, a genus of Plants which gives its name to the natural order *Smilaceæ*. The name occurs in Greek authors, as Theophrastus and Dioscorides, and is applied to several different kinds of plants, as the yew-tree; a species of Phaseolus or Convolvulus (Σμίλαξ τραχεῖα) is *Smilax aspera*, which belongs to the present genus. *Smilax*, is characterised by having a 6-leaved corol-like perianth, with six stamens inserted into their base; the anthers are linear and fixed by the base; ovary 3-celled; ovules solitary, in each cell affixed to the apex; style very short; stigmas 3, spreading; berry 1-3-celled, 1-3-seeded; seeds globular; testa membranaceous, whitish; hilum large and coloured; albumen cartilaginous; embryo very small, remote from the hilum. The species form evergreen climbing shrubs, of which a few are found in temperate, but the majority in warm and tropical regions of both hemispheres, extending south to Australia, and north to Japan, North America, and the south of Europe. The species have fibrous or tuberous roots, stem often prickly; leaves alternate, petiolate; cordate or hastate, nerved, reticulate, venose, conchiferous stipulæ between the petioles; flowers sessile on a globular receptacle; subcapital pediculate and umbellate. Though the original species (*S. aspera*) of this genus is an inhabitant of the south of Europe, those now most celebrated for yielding the different kinds of Sarza or Sarsaparilla are natives of South America. But *S. aspera* still continues to be employed for medicinal purposes in the south of Europe, where it is called *Sarsaparilla Italica*, but there is no truth in the statement of its being the plant yielding Indian Sarsaparilla, which is *Hemidesmus Indicus*. Another celebrated species is the *Smilax China*, which has a tuberous root abounding in fecula, and therefore probably useful as a demulcent, though the Chinese esteem it invigorating, and ascribe to it other virtues. It is remarkable that two Indian species, which, like the Chinese species, have tuberous roots, should be called in Silhet Hurina-Shook-China and Gootea shook-China These are *Smilax glabra* and *S. lanceæfolia*, and their roots cannot be distinguished from the China root, or *Chob-chinee*, as it is called in India. A similar species is common in the southern parts of North America, and has been called *Smilax Pseudo-China*, though there is reason to believe that more than one species may be confounded under this name. *S. glycyphylla* is an Australian species, which has received its specific name from the sweetish taste of its leaves, and has been called Sweet Tea from its employment in the form of infusion, and is probably alterative and diaphoretic, as well as slightly tonic. It is probable that some of the species found in the Old World will be discovered to be possessed of virtues equal to the American species. Some of the Indian species were sent some years ago by Dr. Gibson, superintendent of the East India Company's botanic garden near Poonah, to the Medical Board of Bombay, for trial in the hospitals of that presidency. [See SARSPARILLA.].—*Eng. Cyc.* Dr. Wight gives Smilax [illegible]aculata, 2059; ovalfolia, 809; and Zeylanica, 2057-58.

Together with these we may notice, *S. Roxburghiana, Vern.* "Koomare shook China," and *S. oxyphylla. Vern.* "Chotee or small koomaree;" *S. rigida* and *ferox*, are Nipalese species. *S. elegans*, extends to the Deyra Doon, and *S. maculata* is found in Nepal, Kemaon, and Missouree. *S. prolifera* occurs very generally, and *S. Villandia* on the Morung hills.—(*Royle*). *O'Shaughnessy, p.* 645.

Mr. Royle also mentions a root sold in the bazars under the name of *Ashoba mugrabee*. This is translated sarsaparilla in Dictionaries, and the root much resembles that drug. Its origin is unknown.

Roxburgh states that the natives of India use the roots of the *S. glabra* in venereal and leprous ulcers, and that they also employ the *S. lanceæfolia* very extensively for the same purpose, and in the treatment of rheumatism.

Both these species deserve attentive examination. It seems however that the Ununtamol (*Hemidesmus indicus*) is likely to supersede all the varieties of sarsaparilla not only in Indian but in European practice.—*O'Shaughnessy, pages* 645 *and* 646.

(7701) SMILAX CHINA.

The roots.

Shookchina, Beng. | Chob Chinee, Hind.

Wild in China; the rhizome is hard, large, woody, knotty, brown or blackish externally, white in substance. The root is one of the China roots of the bazars, it is much, and we believe advantageously, employed as a substitute for sarsaparilla. It is largely imported into Calcutta from the Eastward, and much employed by native practitioners.—*O'Shaughnessy, p.* 645. The China root which comes to Ajmere via Bombay: is a largish, insipid, whitish root, in slices. taken as restorative and aphrodisiac in milk, one tola is a dose: used also in mesalihs: one seer costs two rupees. Natives suppose that this is the root of the "hazari," marygold (Tagetes erecta), after being in the ground three years.—*Gen. Med. Top. p.* 131.

(7702) SMILAX GLABRA.

Gootcea shook China, Beng.

A native of Sylhet and the adjacent country. A climber with a large tuberous rhizome. The stem and branches are thornless, leaves lanceolate, pointed, pale green beneath. Flowers umbellate, axillary, sessile and solitary. The root is identical in appearance with the China root of commerce.—*O'Shaughnessy, page* 645.

(7703) SMILAX LANCEÆFOLIA. Eastern Bengal.

Hurria shook China, Beng.

Much resembles the former, the leaves are lance shaped and three-nerved, umbels stalked —*O'Shaughnessy.*

(7704) SMILAX OVALIFOLIA. Wild Sarsaparilla. There or two are more species of smilax in Tenasserim jungles, one of which is used by the natives as medicine, to supply the place of a species of sarsaparilla, whose dried roots are sold in the bazars.—*Mason.* Smilax ovalifolia is indigenous at Dapoorie, and possesses perhaps the virtues of the genuine Sarsaparilla.—*Spry's Suggest. p.* 68.

(7705) SMUT OR DUST BRAND, (Uredo Segetum) is a disease produced in wheat by a fungus, and is said to infect chaff, straw, seeds and leaves.—*Hassell.*

(7706) SNAKE FRUIT. Eleagnus Conferta.

(7707) SNAKE GOURD. Trichosanthes anguina. A curious contorted gourd, peculiar to India, is in very general demand for vegetable curries. The plant is of easy culture on trellises around the doors of the native cabins, and the fruit often grows two feet long, beautifully striped, small, and tapering, so that streaming down from the trellis, they immediately remind one of striped snakes suspended from the foliage of trees.—*Mason.*

(7708) SNAKES HEAD LILY.—Amaryllis Frittilaria.

(7709) SNAKE-WOOD, Letter or speckled wood. A wood bearing this name is used at Demerara, Surinam, and along the banks of the Orinoko, for the bows of the Indians. The colour of the wood is red hazle, with numerous black spots and marks, which have been tortured into the resemblance of letters, or of the scales of the reptile; when fine it is very beautiful, but it is scarce in England, and chiefly used for walking sticks, which are expensive; the pieces that are from 2 to 6 inch diameter, are said to be the produce of large trees, from three to four times those diameters, the remainder being sap. Dr. Bancroft says, "*Bourra courra*, as it is called by the Indians, by the French bois du lettre, and by the Dutch Lettre hout, is the heart of a tree growing 30 feet in height with many branches," &c.

Canjica paise, No. 64, in Mr. Morney's collection of Brazilian woods, is somewhat like snakewood, but less beautiful; it is much less red, and the marks are paler and larger. If not an accidental variety, the wood would be worth seeking.

The above must not be confounded with the snake-wood of the West Indies and South America, the Cecropia, of which there are three species all furnishing trees of straight and tall growth, and a wood of very light structure, presenting sometimes distinct and hollow cells. The Balsas, or floats, used by the Indians of South America for fishing, &c. are very commonly constructed of this wood.—*Holtzappfell.*

(7710) SNOW, RED. The valley, says Hooker, remains almost level for several miles, the road continuing along the east bank of the Lachen. Shoots of stones descend from the ravines, all of a white fine-grained granite, stained red with a minute conferva, which has been taken by Himalayan travellers for red snow; a phenomenon Dr. Hooker never saw in Sikkim. Red snow was never found in the Antarctic regions during Sir James Ross's South Polar voyage; nor does Dr. Hooker know any authentic record of its having been seen in the Himalaya.—*Hooker, Him. Jour. Vol* II. *page* 118.

(7711) SNUFF.

Tabac en poudre, Fr.	Tabacco da naso, It.
Schnupftaback, Ger.	Nosowoi tabak, Rus.
Nass, Guz. Hind.	Tabaco de polvo, Sp.

Is tobacco in a powdered state, and in general use as an errhine. Other articles are sometimes added to vary its pungency, scent, &c.—*Faulkner.*

(7712) SOAP.

Saboon. Arab.	Sapo, Lat.
Zeep Dut.	Saboon, Sujah, Mal.
Savon, Fr.	Sabao. Port.
Seife, Ger.	Mulo Rus.
Saboon. Guz. Hind.	Jabon, Sp.
Sapone, It.	Natsowcaram, Tam.

The manufacture of Soap was known to the Romans, and has long been practised in India. Hard or Castile soap is made by beating together olive oil and a solution of caustic soda. Chemists conceive that at the time when soap is formed, the Elaine and the Margarine are, by a re-arrangement of their elements, converted into two acids, called Elaic and Margaric acids, and that these combine with the Soda forming Eleates and Margarates of Soda. But with the formation of the acids, a new substance, *Glycerine*, is also produced, and becomes dissolved in the water which forms one of the constituents of Soap. Some oils and animal fats contain Stearine, a substance closely allied to Margarine : in that case some Stearic acid is also formed. All Soaps are slightly alkaline, feel soft and slippery, and are detergent. The watery solution is readily decomposed by acids, also by earthy and many metallic salts, hence, when water holds any of them in solution instead of dissolving, the soap becomes decomposed. Such waters are called *hard*, while those which are comparatively pure are called *soft* waters. Castile Soap is composed of 9. to 10·5 of Soda, 76·5 to 75·2 of Oleic and Margaric acids, and of 14·3 to 14·5 of water, (*Ure*). Common Soap made of Tallow and Soda, and Yellow Soap of Tallow, Resin, and soda, are not so well adapted for medical use.—*Royle.*

Soap seems to have been introduced by the Mahomedans into India, though the Hindoos have long used alkaline leys, obtained from the ashes of plants, for many of the purposes of soap ; and they have a substitute for soap in several berries. Soap is made at Dacca, of shell lime, 10 mds. ; *sajie muttee*, 16 mds. ; common salt, 15 mds. ; sesamum oil, 12 mds. ; goat's suet, 15 seers. It is made of good quality at Saharunpore ; and some marine soap, of excellent quality though in small quantity, was sent to the Exhibition of 1851 from Calicut.—*Royle Arts &c. of India, p.* 484. Soap is an article of which a considerable quantity is made at Dacca. It is considered the best in India ; and like the Soap of Tranquebar, which is also of an excellent quality, it was formerly an export to the Mauritius, Penang, Sumatra, and the Islands of the Indian Archipelago. It is made of sajee mathee (impure carbonate of soda) sesamum oil, common salt, fine shell lime, and goat's suet. The manufacture of this article is carried on by Mahomedans, by whom it appears to have been introduced into India. The Arabic word *saboon* indeed, is the origin of the names given to soap in many countries, as that of *sabun* in the Crimea, and *savum* at Genoa. (See Dr. Clarke's Travels in Russia, and on the Don.) *Dr. Taylor.* At the Madras Exhibition of 1855, several samples of soap were exhibited and carefully examined by Mr. Stanborough. The best appeared to be a cake of castor oil soap, exhibited by Dr. G. W. Flynn, for which the Jury awarded a 2nd Class Medal.—*M.E.J.R.*

(7713) SOAP ACACIA. Acacia Rugata, Buch. The dried pods of this plant are sold in the Bazars of the Tenasserim provinces, and used as a substitute for soap in cleansing the hair. —*Mason.*

(7714) SOAP NUTS.

Reeta, Arectah. Duk. Guz. Hind.	Poovandie cottay Manay poongung kai. Tam.
Rarak, Mal.	Koomutti ghenzaloo, Tel.
Bindake-i-hindee, Pers.	
Arishta, Phenila, Sans.	

These capsules, which contain black seeds, have a singular sweetish bitter taste, and a smell not unlike that of an over-ripe mango. They are used medicinally by native practitioners ; and form, when bruised and agitated in water, a kind of sud like that of common soap, which is extensively used by the natives in India for washing their heads ; and by washermen for cleaning silks. The pounded seeds are said to be a valuable remedy for epileptic paroxysms, and other diseases. Soap nuts are procurable in most bazars.—*Faulkner.*

(7715) SOAP-NUT OIL—Sapindus emarginatus.

Poovandie cottay, or Poongum-kai yennai, Tam.	Koocoodie noona, Tel. Reethay ka tael, Hind.

This semi-solid oil is used medicinally by the natives, and is extracted from the kernel of the Soap-nut. Its cost prevents its general use. Excellent specimens are shown by the Trichinopoly Local Committee, and Lieut. Hawkes, also fair samples from Tanjore and the Madras Tariff.—*M. E. J. R.*

(7716) SOAP NUT TREE, Sapindus emarginatus.

Poochee-cottay, Tam. | Reethay ka jhar, Hind.

A tree met with about villages all over the country. The fruit used as indicated by the native name and sold in all bazars. Wood white, only used for fuel. In many situations, this tree yields a more profitable return than any other fruit tree. Wight No. 75, Hort. Garden. —*M E. J. R. The Soap Nut Tree.* These trees are very common in the Deccan villages. The leaves have a shining appearance,

and the flower stalk a soft brown downy look, bearing a small whitish flower. The berries are used for washing by the natives.

Resembles the S. Indicus. The seeds are used medicinally, and also for washing the finer kinds of silk.—*Riddell.*

(7717) SOAP, SOFT, as used in the arts, is made with Caustic Potash and Fish-Oil and Tallow; is semitransparent, of the consistence of honey, brownish-coloured, and nauseous. But that referred to by the Colleges as made with Potash and Olive Oil, Dr. Pereira was unable to meet with, and found on inquiry that common Soft Soap is usually substituted in making *Ung. Sulphuris Comp.*—*Royle.*

(7718) SOAPSTONE, STEATITE.

Sunkjeeroo. HIND. GUZ. | Bulpum, TAM. TEL

This mineral has a soft and greasy feel; is of a yellowish white or greenish gray colour; sometimes spotted or veined; with little lustre or transparency. It is composed of silica, magne-alumina, oxide of iron, and water, in various proportions, according to the variety and the place whence obtained. It occurs at the Lizard Point in Cornwall; and is used for porcelain manufactures.—*Eng. Cyc.* Soapstone is met with in India, where it is known by the name of *Sunkjeroo.* also *Bulpum.*—*Faulkner.* Soapstone, potstone, or steatite, is constantly for sale in the stalls, in Tenasserim, being used by the Burmese to write with on their black boards, as Europeans use chalk. It is not however a production of the Provinces but is imported from Burmah, where it is abundant.—*Mason.*

(7719) SOAP WORTS; Soap-fruits and Soap-nuts in tropical climates furnish substitutes for soaps, of a more or less useful character. Several of them are well known in Eastern Countries, and the dried berries of the Soap-worts, to which the genus Sapindus belongs, are to be found in almost every bazar, being used throughout India for special purposes, such as in washing silk, or hair, or woollens and cloths of various kinds.

In the W. Indies and the continent of America, *Sapindus saponaria* yields the so called soap berries, and, in Java, *Sapindus Rarak*: In India, several species, as *Sapindus Laurifolius, Sapindus acuminatus, Sapindus emarginatus, and Sapindus detergens,* yield berries, used as above. The fleshy part of these sapindus berries is viscid, and when dry and rubbed with water, they form a lather like soap, and the bark and roots have similar properties, though it is said that articles washed by the root and bark rapidly corrode. Hindoo physicians deem the *endocarp* a useful expectorant, and it is said the seeds, pounded with water and a small quantity put into the patient's mouth, often put an end to the epileptic paroxysm. The tincture or extract, of the Soapy matter of the Capsules of saponaria has been used in chlorosis. The berries, which are about the size of cherries, inclose black shining nuts which take a fine polish, and were formerly much used in England for making bottons after having been tipped with gold, silver or other metal. They are also made into beads, necklaces &c. The kernel contains an edible oil, which is sometimes used for burning. In India the nuts of the *Rheeta, S. emarginatus,* are eaten by young people, and in the West Indies, the fruits of S. Senegalensis and S. esculentus are deemed as palatable as the hazel nut and almond The *Sapindus* genus gives its name to the *Sapindaceæ,* the national order, to which it belongs. S. rubiginosus is a close-grained, hard wood, and forms an excellent timber. *Saponaria vaccaria,* is well known in India, and is identical in its properties with S. officinalis, a decoction of the root, frothing like a solution of soap.—*Kritz, kris, or kreess,* the root of some parisitical plant, but of unknown origin, is used in Cashmere to wash the shawls, soap being used only for the white shawls: It is used also medicinally, and for dyeing the color called na-furmanee.

(7720) SODA.

Jumd chenee, ARAB.
Sujacara, CAN.
Hydrate de Soude, FR.
Astz-natron, GER.
Sedjee Mittee. Sajeekhar (impurecarbonate) Papudkhar (sub-carbonate) GUZ. HIND.
Neter, HEB.
Charum, MAL.
Sajee-khar, Papud-khar PERS.
Sarjica, Sarjikashara, SANS.
Karum, Ponheer karum, TAM.
Savittie-munnoo-ooppoo, TEL.

The substance known in commerce by the name of soda is a carbonate of soda, but mixed with various impurities, according to the source whence it has been obtained; that is either from the Natron lakes, from the soda soils, from the burning of sea-weeds, or from the decomposition of other salts of soda. In commerce, soda generally occurs as a carbonate, as above stated, or in the impure forms of Barilla and Kelp. Barilla is the ash obtained by burning plants on the shores of the Mediterranean, of the Red Sea, and Indian Ocean. Kelp used to be prepared on the coasts of Scotland and its Islands, also on those of Ireland and Wales, and on that of Normandy in France, by burning a great variety of sea-weeds. In its original state, soda is of a gray colour, and fracture vitreous: it is an article of the greatest importance in the soap-glass, and other manufactures.

The Arabic name, *sagimen,* seems to be derived from the Hindoo *saji-noon,* that is, sajji, or soda salt. Nitre must have been produced then, as now, in their soil, and borax imported from Tibet, while sal-ammoniac must have been produced ever since they made bricks, as they now do. Alum is in India, obtained by throwing potash on alum slate, which has been sometime exposed to the air.—*Royle, Arts. &c. of India, p.* 463.

Dr. Taylor gave the following as Asiatic Salts of Soda.

Soda, from ashes of species of Salsola and Salicornia, on the Coromandel Coast.
Sujjee or carbonate of Soda, in Tirhoot.
Oosur Salt, Mirzapore, &c.
Lanee Kharee, Scinde.
Natron, from Lonar Lake in Lat. 20° and Long. 76° 30.
Mineral Alkali, Bombay.
Salt, common, (Chloride of Sodium,) Tumlook, Balasore, Tanjore.
,, or Samur, Samur or Samur Lake.
,, Rock Salt, Salt Range of Punjaub,
Borax, Kemaon and Gurhwall, from Tibet.
Khara Noon, (Sulphate of Soda,) Gyah, Tirhoot, &c.

(7721) SODA BIBORAS, SODÆ BORAS, BORAX, Biborate of Soda. Borate of Soda.

Borax Borate de Soude, FR.	Boraxsaures Natron, G.
Sohaga, HIND.	Tincana, SANS.

Borax or (Na O, 2 B O_5 + 10 Aq =192) Biborate of Soda, is supposed to have been known to the ancients, and to have been the *Chrysocolla* of Pliny. The Hindoos have long been acquainted with it; it is their *Sohaga*, Sanscrit *Tincana*, and one of the kinds of *Boorak* of the Arabs. Its nature was first ascertained by Geoffroy in 1732. It is produced by spontaneous evaporation on the shores of some lakes in Tibet, that is, in the same country, with Musk and Rhubarb; brought across the Himalayan Passes into India, and imported into other countries by the names of *Tincal* and *Crude Borax*. It is also obtained by saturating the Boracic Acid of Tuscany (p. 37) with Carb. Soda. Crude Borax is in pale greenish pieces, covered with an earthy coating, and feels greasy to the touch. The natives of Tibet are said to cover it with some fatty matter, to prevent its destruction by efflorescence. It is purified by calcining, which destroys the fatty matter, or by washing with an alkaline ley, which converts it into a kind of soap, then dissolving and re-crystallizing. It crystallizes in irregular hexahedral prisms often terminated by 2—4 converging planes. Sp. Gr. 1·35. It is colourless, transparent, somewhat shining; taste sweetish, a little styptic, and subalkaline. It has an alkaline reaction on Turmeric. The crystals effloresce slightly in the air, are soluble in 12 parts of cold and 2 of boiling water. When heated, they lose water, swell up into a porous substance called *Boraæ usta v. calcinata*, and at a red heat run into a transparent glass called *Glass of Boraæ*, much used as a flux. Another variety, more useful in the arts, contains only 5 Eqs. Aq., and crystallizes in octohedra, which are permanent in the air. Borax increases the solubility of Cream of Tartar, p. 86, and converts mucilage of Lichen and of Salep into a thick jelly. Comp. Na O 16·0 Bor' 35·79 Aq. 47 37=100.—*Royle.*

(7722) SODÆ CARBONAS, L. E. D. Carbonate of Soda. (Sodæ Subcarbonas. Aerated Mineral Alkali. Fossil Alkali. One of the kinds of *Nitrum* of the ancients, is the *neter* of the Hebrews. It was known to the early Hindoos, and is by them called *Sajji noon* (i. e. *Sajji* or Soda Salt); it is the *Sagimen vitri* of Geber. The Natron lakes of Egypt were known to the ancients, and it was early employed in glass-making, &c. Carbonate of Soda is a very valuable article of commerce being largely used not only in medicine but in arts and manufactures; but it is made from common Salt on a large scale in England, and so cheap that, it is a question if our Indian article, though a natural product, could compete with it in the market.—*Royle.*

(7723) SODA, IMPURE CARBONATE OF. CARBONAS SODÆ IMPURUS.

Barilla is the Ash obtained by burning plants, on the shores of the Mediterranean, of the Red Sea, and Indian Ocean. These plants belong mostly to the natural family of Chenopodeæ, q. v.; and chiefly to the genera Salsola, Salicornia, Suaeda, and Chenopodium. The quantity of Carbonate of Soda in the ash varies from 25 to 40 per cent, and is produced from the combustion of the Oxalate and other Salts of the Vegetable Acids. The soda is no doubt obtained from the soil, for Du Hamel planted Soda-plants inland, and they yielded only Potash. Infusion of a Salsola in cold water afforded by evaporation two Salts, Carbonate of Soda and Chloride of Sodium. *Murr. Chem.* ii. p. 612. A portion of the Chloride is no doubt converted into the Carbonate during the incineration.

Kelp used to be prepared on the coasts of Scotland and its islands, also on those of Ireland and Wales, and on that of Normandy in France, by burning a great variety of Algæ or Sea-weeds. The ashes when cold form *Kelp*, which is in hard cellular masses, of a bluish grey colour, and of a disagreeable alkaline taste, containing from 3 to 8 5 per cent. of Carbonate of Soda, and other salts, as in the case of Barilla, but also some Potash and Iodine (v. p. 4:). Carbonate of Soda is, however, now obtained very cheaply from Chloride of Sodium or Sea-salt. This is first converted into Sulphate of Soda by the action of Sulphuric Acid then mixed with pounded small Coal and Chalk, and heated in a reverberatory furnace and stirred. The Carbonaceous matter abstracts Oxygen both from the Sul. Ac. and the Soda; Sulphuret of Sodium is formed, and decomposed by the Lime; Carbonate of soda, insoluble Oxi-

Sulphuret of Calcium, caustic Soda, and Carbonaceous matter being the result. The insoluble parts are separated by lixiviation, and the Sulphur subsequently burnt away; during which the Soda is completely Carbonated. The mass now contains about 50 per cent. of Soda. Being lixiviated and evaporated, the Carbonate is obtained in large crystals. As Barilla is not sufficiently pure for medicinal purposes, the L. and D. Colleges give directions for its purification. The E.C. justly consider the Carbonate of Soda produced as above, pure enough.—*Royle.* Ainslie tells us that some of the more enlightened vyteans knew how to prepare Carbonate of soda from saline earths which contain it, such as Ovar Munnoo, and Poonheer. The soda prepared from the first, the Hakeems of lower Hiudoostan called "*Chour ke muttie ka nemuck,*" that from the second they call "Chowr ke pool ka nemuck."—*Ains. Mat. Med. p.* 43.

(7724) SODA, MURIATE OF. This mineral salt of very fair quality was exhibited from Bangalore, Bellary and Hyderabad, and is known to occur also in the Guntoor and Nellore Districts, and to be almost invariably accompanied with some interesting minerals, viz. Gypsum, magnesian limestone, sandstone, sulphur, red and brown iron ores, and Alum slate; as most of these minerals have come in from the districts that produce the mineral salt, it would be worth while to direct further search to be made in the vicinity for the sulphur and Alum slate, both of which are valuable products. Sulphur was exhibited from several Districts associated with the above and other combinations. Alum slate is also exhibited from the Cuddapah District, Vellore and the Neilgherries, but the accompanying minerals had not been forwarded. It is of great importance that the minerals associated with Rock Salt and Gypsum should always be recorded or collected, as Fossils of some kind or other almost invariably occur in the vicinity, and these are the best and safest guides for determining the relative ages of the accompaying strata. The following interesting description of the Salt Range in the Punjaub, by Dr. Jameson, will show the importance of this class of formations. The Salt Range, extends from the Eastern base of the Suliman Mountains to the River Jhelum in the Punjaub. Lat 32° 30'—33° 20'

The rocks in this part of the range are, first (1) Magnesian Limestone, (2) New Red Clay and sandstone, (3) Fossiliferous sandstone, (4) Red Clay and sandstone containing Coal and Mineral Sulphur, Rock Salt, Gypsum, brown and red Iron ore and Alum slate. The lower beds contain no organic remains but the upper abound in them. The Iron ore is a red or brown Haematite, so rich that in many places the needle of the compass becomes quite useless even at a considerable distance from the Rocks owing to their being highly Magnetic, from the quantity of Iron which they contain. The sandstone abounds with the Exuviae of enormous animals either Saurians or Sauroid fishes.

The Hills at Kala Bagh contain great quantities of Aluminous slate from which Alum is obtained at various manufactories in that Town. The slate well sprinkled with water is laid in alternate strata with wood, until the pile reaches a height of 25 to 30 feet; it is then lighted and the combustion continued for about twelve hours, in which time the color of the slate is converted from greyish black to dark red. This change of color indicating that the process has been carried to a sufficient extent, the mass is thrown into a tank holding as much water as it is computed the Alum is competent to saturate. After three days the water, which becomes of a dark red color, is drawn off, mixed with a due proportion of potash and boiled down. The residuum on cooling becoming a solid mass of Alum.

A very interesting series of salts consisting chiefly of the Muriate and carbonate of soda from the Loonar Lake in the Hyderabad territories was exhibited by Dr. George Smith, Residency Surgeon Hyderabad. These have already been carefully examined by Professor Mayer and reported upon at some length in Vol. 1, New series of the Madras Journal of Literature and science. The following is a condensed epitome of the Report, and of the chemical composition of the salts:—

No. 1. Dulla.

This is a Carbonate of Soda with a faint trace of Muriate of Soda and about 2 per cent of impurities.

No. 2. Nimmuck Dulla.

Is nearly pure Muriate of Soda.

No. 3. Khuppul.

Is carbonate of Soda, with water and about 2 per cent of impurities.

No. 4. Puppree.

Is nearly pure Carbonate of Soda.

No. 5. Madkhar.—This is an impure salt containing Carbonate of Soda, 27
Clay and sand,. 30 } water about 17.
Common Salt,. 25

No. 6. Bhooskee.

This is also a crude impure substance

containing Neutral Carb of Soda.	26
Insoluble matter chiefly sand and Clay,	58
Water, ...	15
Common Salt, ...	2

No. 7. Travertin.

This contains Carb of Lime, ...	78
Carbonate of Magnesia,...	4
Insoluble matter with Oxide of Iron &c.	9
Chloride of Sodium, ...	2
Water, ...	3

The Natron lake of Loonar occurs in the Circar of Meinker Soubah of Berar about 45 miles N. W. of Hingolie in Lat. 20 N. it is about 510 feet below the level of the surrounding ground

in a kind of Crater of 5 miles in circumference, the lake being about 3 miles in circumference and surrounded by luxuriant vegetation; springs of clear soft water occur close to the lake, which has evidently been extending its bounds lately, as numerous dead trees are standing within its margin, and a bowrie of sweet water protected by a wall is now completely surrounded by the water of the lake. An intolerable stench of sulphuretted hydrogen is emitted by the lake during the heat of the day and its waters prove destructive to animal and vegetable life, though flocks of Duck and Teal dot the surface of its waters. There are two saline springs near the Centre of the Lake and about ½ a mile apart. These never become dry. It is supposed that the muriate of Soda from this source coming in contact with the carbonate of Lime which abounds in the vicinity causes the deposition of the carbonate of Soda or Natron Salt in a greater or less state of purity. The depth of the lake near the salt springs varies from 6 feet during the hot months to 12 or 14 feet during the rains. The Salt is raised by divers who bring it up in their hands, it is much prized and finds a ready sale in Berar, Nagpore, Candeish, and Poonah, to which places it is carried in Bamboo baskets and retailed by dealers. The lake has not been regularly worked since 1836 in which year 2,136 candies of the different Salts were raised, valued at Rs. 60,081. In 1853 Major Johnston rsised 35 candies valued at Rs. 1,461-4-0.

Some suggestions have been proposed for increasing the productiveness and revenue of the lake. These are contrivances for preventing the flushing of the Lake with water, supplied by the main feeder, and by several streams from the surrounding water shed, such as bunds and channels.—*M. E. J. R.*

(7725) SODA, NITRATE OF, CUBIC NITRE.
Nitrate de Soude, FR. | Wurfelsalpetre GER.

Consists of nitric acid and soda. It is similar in its properties to saltpetre, differing chiefly in being more pungent in taste, more soluble in cold water, more inclined to attract moisture from the atmosphere, and in crystallizing in a rhomboid form. It is highly esteemed as a manure for pastures, and for all other sorts of agricultural produce, except that grown in heavy wet soils. It is also applied to many of the purposes for which saltpetre is used, though being more deliquescent than that salt, it is not adapted for the manufacture of gunpowder. This salt is found in immense quantities in deposits in South America, particularly in the districts of Atacama and Tarapaca in Peru.—*Waterston. Faulkner.* Samples of this Salt were exhibited at the Madras Exhibition of 1857, from Bellary and Hyderabad, where it seems to form a natural efflorescence. Its chief use is as a substitute for saltpetre for the manufacture of Nitric and other acids and chemical substances. It is too deliquescent for making gunpowder, though it answers well for some descriptions of fireworks. The samples exhibited were indifferent.—*M. E. J. R.*

(7726) SODÆ SESQUICARBONAS. Sesqui-Carbonate of Soda. Natron.

Anderthalb Kohlensaures Natron, GER. | Natron, FR.

A Sesqui-carbonate of Soda ($NaO\ 1\frac{1}{2}\ CO_2 + 2\ HO = 83$) exists in nature; for the Trona found near Tripoli in Africa, the Natron of the country to the west of the Delta of the Nile, and of the Lonar Lake described by the late Dr. Malcolmson, have all been proved to consist of $1\frac{1}{2}$ Eq. of Carbonic Acid to 1 of Soda; or Na O 38·55 + C 39·76 + Aq. 21·69=100. The analyses were made in the Laboratory, and the specimens are deposited in the Museum, of King's College. A solution of it may be obtained by heating Bicarbonate of Soda in solution to a temperature of 212°.—*Royle.*

(7727) SODÆ (SESQUICARBONAS, L.) BICARBONAS, E. D. *Sodæ Carbonas.* Bicarbonate, and Carbonate of Soda of the shops.

Zweifach Kohlensaures Natron, GR. | Bicarbonate deSoude, FR.

The Bicarbonate of Soda ($NaO\ 2CO_2 + 2HO = 94$) of the E. and D. P's is the same salt as the Sesqui-carbonate of the L. P. That which is met with in commerce is usually a pure salt, but occasionally mixed with a small portion of the Carbonate. It exists in some mineral springs highly acidulated with Carb. Ac., as in those of Vichy.

Prop. As usually sold, it is colourless, in powder, or in minute scale-like crystals, having a saline, slightly alkaline taste and reaction.—*Royle.*

(7728) SODA, SULPHATE OF. L. E. D. Sulphate of Soda. *Natrum Vitriolatum. Sal Catharticus. Sal mirabile Glauberi.*

Sulphate de Soude, FR. | Nemuck, PER. & HIND.
Schwefelsures Natron, GER. | Malh. ARAB.
Oopoo, TAM. & TEL. | Noona, HINDEE.

Sulphate of Soda ($Na\ O, S\ O_3 + 10\ Aq. = 162$, or Glauber's Salt, is found effloresced on the soil in some countries, as in India, where it is called *kharee nimuk* or *kharee noon.* It exists in sea-water, in that of some lakes and mineral springs, also in Glauberite. It is found in the ashes of many plants, and in some animal secretions.—*Royle.* In Bengal, *Sulphate of Soda*, or Khari Noon, is an impure sulphate of soda extracted from an earth in which the salt exists, in the proportion of from ten to fifty per 100. It is prepared in large quantities by simply washing the earth. It is usually sold in crystalline dirty brown masses. These are purified by a simple process often described.—*Beng. Phar. p.* 362.

(7729) SODII CHLORIDUM, L. SODÆ MURIAS (PURUM, E.) E. D. Chloride of Sodium. *Muriate of soda.* Sodæ Murias purum, E. *Sal Fossile. Sal Marinum. Sal Gemmæ.*

Chlorure de Sodium, FR. | Chlor Natrium, GR.

Chloride of Sodium (Na Cl=60), or Common Salt, is abundantly diffused in nature, and, being an essential article of diet, must have been known from the earliest ages. It is found in many animal solids and fluids, and in the juices of some vegetables. It exists in large quantities in the solid form as Rock Salt, or in solution in some springs, and everywhere in sea-water. From these it is obtained by evaporation, when it crystallizes with slight variations of appearance according to differences in the process. These varieties are known by different names in commerce, as Butter, Stone, and Basket Salt, also Sea Salt, and, in large crystals, as Malden, Fishery, and Bay Salt. Most of the kinds of Salt require purification, by being again dissolved and re-crystallized (Sodæ Murias purum, E.) as they are apt to contain other salts, as alkaline and earthy Sulphates and Chlorides, especially of Magnesium and of Calcium.—*Royle.*

(7730) SO-E. A garment of leaves, which, as well as hats, is fabricated by the agricultural laborers of Northern China, from the leaves of *Chamærops excelsa*, a palm indigenous in the Northern and Central parts of that country: but in the Southern districts of China, the *So-e*, is made from the leaves of the Bamboo and of other broad leaved grasses.

(7731) SOI KEERY, *Tam.* This green, says Ainslie, I have never seen, nor do I believe that the Botanical name of the plant has been ascertained. It grows in the Southern parts of the Peninsula and is eaten by the poor.—*Ains. Mat. Med. p.* 257.

(7732) SOJA, a genus of Plants belonging to the natural order *Leguminosæ*. *Soja hispida* (Mœnch), *S. Japonica* (Savi), the *Dolichos Soja* (Linn.), is a native of Japan and the Moluccas, and abundant in the peninsula of India, though probably introduced there. The seeds resemble those of the haricot, French or kidney bean, and are used by the Chinese to "form a favourite dish called 'tau-hu,' or 'tau-hu,' which looks like curd, and which, though insipid in itself, yet with proper seasoning is agreeable and wholesome." The Japanese call the seeds 'Miso,' and put them into soup, of which they sometimes partake three times a day. They likewise prepare with them the sauce termed 'Sooja,' which has been corrupted into 'Soy.' Soy is only sparingly used as a sauce in this country. It has the character of being a useful stomachic, but not more so than any of the other condiments when used with moderation.—*Eng. Cyc.*

(7733) SOLA, frequently *Shola*, is the name of a Plant common in moist places, and in the rainy season in many parts of the plains of India. It belongs to the genus *Æschynomene*, and has been called *Æ. aspera* by Linnæus, from the lower part of the stem being rough and scabrous, as well as the legumes. It has been called *Æ. lagenaria*, both by Loureiro and Roxburgh. The plants are remarkable for their light and spongy texture, and seem indeed to be composed almost entirely of pith. On this account the thicker stemmed plants are collected in the dry months and the light substance applied to a variety of uses, as for making some kinds of toys, and the floats of fishermen's nets; cut into thin slices and pasted together, they are much employed for making hats, which, being light and having broad brims, are well suited for protecting the head from the influence of the powerful Indian sun, especially if a handkerchief be put loosely into the crown of the hat. This substance has also been employed for lining drawers of natural history, and in its texture very much resembles the substance called rice-paper, which is the pith or stem of a Malvaceous plant cut into thin slices.—*Eng. Cyc.*

(7734) SOLANACEÆ, a natural order of Plants belonging to the dicarpous group of Monopetalous Exogens. This order is composed of herbs or shrubs, rarely of arborescent plants, with colourless juices, round or irregularly angled stems or branches, sometimes armed with thorns or prickles; their leaves alternate, simple, entire, or lobed. The inflorescence is variable, mostly axillary, sometimes terminal; pedicles without bracts, and the flowers regular and united. The plants of this order are natives of most parts of the world, without the arctic and the antarctic circles, and especially within the tropics. The order is one of the most important and interesting in its class, from its bringing together plants of the greatest utility, yet possessing apparently opposite properties. It is a great advantage of a natural system that it brings together not only plants that are allied in structure, but in properties also; but this order seems to form an exception. The Deadly Night-shade, the esculent Potato, the pungent Capsicum, the mild Tomato, the wholesome Egg-plant, and the poisonous Tobacco, are all found here. They will all however, on close examination, be found to possess the same properties in a greater or less degree. The potato, the tomato, and egg-plants possess, when uncooked, in a mild degree, the properties of the Nightshade, the Stramonium, and the Henbane, confirming the remark of De Candolle, "that all our aliments contain a small proportion of an exciting principle, which, should it occur in a much greater quantity, might become injurious, but which is necessary as a natural condiment." In fact, when food does not contain some stimulating principle, we add it in the form of spices. Many of the plants of this order are used in

medicine, amongst the most valuable of which are Henbane [HYOSCYAMUS], Deadly Nightshade [ATROPA], Bitter-Sweet [SOLANUM], Stramonium [DATURA], and Tobacco [NICOTIANA]. The species of *Physalis* were formerly used in medicine, but are not now in repute in England. *P. Alkekengi*, the Common Winter Cherry, is grown as an ornamental plant; and in Arabia, and even Germany and Spain, the berries are eaten as a dessert. *Lycium barbarum* is known in England as Tea-Plant, and has been recommended as a substitute for the Chinese plant. The Calabash-Trees of the West Indies and the American continent are different species of *Crescentia*, which is often referred to this order. The fleshy pulp of the fruit of some is eaten, but in most species is deleterious. The most valuable part of the calabashes is their rind, which is tough, and is applied by the negroes to a variety of purposes. Cups, mugs, bowls, basins, and saucepans, are made from them, and many other articles of household use. Cayenne-pepper [CAPSICUM] is the produce of the order, as well as the potato, tomato, and egg-plant [SOLANUM], which are used extensively as articles of diet.—*Eng. Cyc.*

(7735) SOLANUM, the name of one of the most extensive genera of Plants, the type of the natural order *Solanaceæ*. This genus is distinguished by the following characters:—Calyx permanent, 5-10-parted; corolla rotate; anthers oblong, connivent, opening by two pores at the extremity. Fruit a berry, subglobose, 2-celled, sometimes 3-4-celled. The species are herbs or shrubs, unarmed or prickly, rarely spiny. The leaves are entire, sinuated or lobed, mostly alternate. Upwards of 400 species of plants belonging to this genus have been enumerated, including many with apparently very opposite properties. The esculent Tomato, the Egg-plant and the invaluable Potato, with the various species of poisonous Night-Shades, are found united so closely by botanical characters that it is impossible generically to separate them. The properties of these plants however do not differ in kind but in degree; and the berries and leaves, and even the tubers when uncooked, of the Potato, possess in a mild degree the narcotic properties of the poisonous Night-shades. Many of them have also very handsome flowers, and are much cultivated in English gardens and greenhouses. From the immense list of species belonging to this genus, we shall select for description a few of those that are used as medicines, or food, or are much cultivated. Several of the species of *Solanum* are recorded as having medical properties. *S. Jacquini* is considered by the native practitioners of India as an expectorant; *S. Bahamense* is used as a gargle for sore throat in the West Indies; *S. mamosum*. *S. paniculatum* and *S. cernuum*, have the reputation of being diuretic and astringent.—*Eng. Cyc.*

(7736) SOLANUM. *Species.*

Vatarajakoolo, CAN.

Vatarajakooloo is the Canarese name of a species of wild Brinzal (without thorns) which is eaten by the Natives on the Malabar coast.—*Ainslie, p.* 246.

(7737) SOLANUM ÆTHIOPICUM. ÆTHIOPIAN NIGHTSHADE. Stem herbaceous, leaves ovate-repand, angular; peduncles usually 1-flowered, drooping. Berries torulose. It is a native of Ethiopia, China, and Japan. There are two varieties recorded: one, the *Æ. violaceum* is a native of China, and the fruit is frequently eaten in that country as a dessert. It has a large spheroid oval berry of a red colour. The other variety is the *S. Æsculentum*, having a prickly stem, and small yellow berries of the size of peas.

(7738) SOLANUM DULCAMARA, Woody Nightshade, or Bitter-Sweet. Stem shrubby, thornless, climbing, flexuous; leaves cordate, upper ones jagged; corymbs almost opposite the leaves. It is a native of Europe, Asia and North America, in hedges and among bushes. It is plentiful in Great Britain. It has purple flowers and crimson berries, which latter may be mistaken by children for red currants, a mistake that has sometimes been attended with fatal consequences.—*Eng. Cyc.* It is a native of temperate climates, a shrubby twining plant, with scarlet, oval, bitter and juicy berries. These are acrid narcotics, and poisonous in moderately large quantities. The young stalks and tops have been much used in medicine as a diaphoretic and alterative, especially in the treatment of cutaneous diseases, and in asthma; in lepra, psoriasis, and similar affections, it is said to be employed externally with good effect. It is on the whole, however, an unimportant article, and not likely to be much prescribed in Indian practice. The Sol. Dulcamara, or a variety thereof, is found on the Choor mountain. (*Royle.*) —*O'Shaughnessy, p.* 462.

(7739) SOLANUM INCERTUM.

Mannuttha-Kalee, TAM.

The leaves are used as a pot herb. The fruit and leaves in the preparation of chatnies; cultivated by the natives commonly.—*Jaffrey.*

(7740) SOLANUM JACQUINI. Fruit of Jacquin's Nightshade.

Cundungkatre kai, TAM. | Vankoodakai, TEL.
Dorle ka pull. DUK. | Kuntakari, SANS.

This is the edible produce of a low growing prickly (medicinal) plant, used only by the common people. See article Cundungkatri vayr in Ainslie's Catalogue 1st, Section 3d.—*Ainslie, page* 239.

(7741) SOLANUM LYCOPERSICUM. Lin. LOVE APPLE or TOMATO.

Seemie Takalie pullum, also Thuckkalee, TAM. | Tamatie, MALAY.

This is chiefly cultivated by the European inhabitants as a valuable ingredient in soups and

stews.—*Ainslie, p.* 232. Is used also for sauces, chatnies, garnishing, soups, &c. : produces the best fruit when trained on a trellis; more a luxury than valuable as a vegetable.—*Jaffrey.* The large lobed, red berries, and very succulent, of the Tomata, or love-apple, contains much malic acid, and used in sauces.—*O'Sh. p.* 463. Solanum Lycopersicum of Linnæus, is the Common Love-Apple or Tomato. This, with some other of the older species of *Solanum*, now form the genus *Lycopersicum*, which is distinguished by possessing a calyx 5-6 parted; corolla rotate, 5-6-cleft; stamens 5; anthers conical, connate at their extremities by an elongated membrane, and dehiscing lengthwise inside; berry 2-3-celled; seeds villous. The present species is called *L. esculentum*; it has herbaceous pilose stems; unequally pinnate leaves; leaflets cut, attenuated at the apex, glaucous beneath; flowers many, united; berries torulose. This plant is a native of South America, but it is much cultivated and well known in Southern Asia, United States of North America, and in France, Germany, and Italy. When ripe, the fruit has an acid flavour, and is added to soups, sauces, &c. It is also used in confectionary as a preserve, and sometimes as a pickle. It is not often used in Britain, but in Italy, near Rome and Naples, whole fields are covered with it, and scarcely a dish is served up into which it does not enter as an ingredient. In the cultivation of these plants, in England, the seed should be sown in March in a hot-bed, and when 2 inches high they may be pricked out into another hot-bed. In May they should be transplanted into a warm south border, where they may have the full sun, and the fruit may ripen quickly. The stem runs up 6 or 8 feet high, and should be trained to stakes or nailed up a wall or poles. The fruit begins to ripen in August, and may be gathered in October, and, when kept dry, will keep good till November. There are several varieties cultivated; the best are called the Large and Small Cherry and Pear-Shaped Red, and the Large and Small or Cherry-Shaped Yellow. The size of the fruit is seldom larger than a golden-pippin apple. (Don's Miller, vol. iv., p. 444).

(7742) SOLANUM MELONGENA, Egg-Plant, Mad Apple, or Jew's Apple.

Bengan, Brinjal, Hind. | Kuthecreekai, Tam.

This is everywhere cultivated in India and Cashmere. The fruits large, ovoid, firm, and innocent, insipid.—*O'Shaughnessy, page* 463. Several varieties are largely cultivated as a vegetable in Ajmere.—*Gen. Med. Top. page* 183. It is one of the most useful of Indian vegetables; and is used in culinary purposes in various ways, The large Cape varieties are the best; commonly cultivated and used by Europeans and Natives; require good soil and abundance of water.—*Jaffrey.*

Stem herbaceous, woody at the base, clothed with starshaped hairs; ovate serrated leaves flowering peduncles reflexed; fertile peduncle solitary, sterile one racemose; calyx campanulate corolla angular. It is a native of the East Indies and also said to be of Arabia. This plant has purple flowers, and bears large, smooth, shining berries, which are the shape and size of a small hen's egg. Two varieties of this plant are recorded—the *S. M. oviyerum*, in which the stem, calyx and leaves are without thorns; and the *S. M. esculentum*, in which these parts are more or less covered with thorns. Several sub-varieties of both these are recorded, varying in the shape and colour of the fruit. The berries are mostly of a white colour, but in some of the sub varieties they are yellow, red, purple, and black. The fruit of this plant is used by the French and Italians in stews and soups. For this purpose the varieties used are the oval-shaped white, the globular-shaped white, and the purple or violet-coloured of both forms. In cultivating them in Britain, they may be reared in hot-beds in rich light soil, or in fine summers they will even produce their fruit in that country against a wall, if planted out in June after having been struck in a hotbed. See Bayngum also Egg Plant.—*Eng. Cyc.*

(7743) SOLANUM NIGRUM.

Arrub ul-salib, Arab.

Common or Garden Nightshade. Stem herbaceous, without thorns; leaves ovate, bluntly toothed, and waved; umbels lateral, drooping. Throughout Europe it is a weed in cultivated ground, and is also found in Africa and Asia. It is common in gardens, fields, and waste places in Great Britain. It has white flowers, producing small berries of a black colour.—*Eng. Cyc. Solanum Nigrum* grows in waste places in most countries, and is employed as a narcotic by the Hakeems. The fruits are very dangerous, and act in the same manner as those of the belladonna mandrake. The extract of the whole plant according to Orfila, acts like *lactucarium*.—*O'Shaughnessy, page* 462.

(7744) SOLANUM NIGRUM, Fox Grape Var.

Munna Takalie pullum, Tam.	Ruba Tarbuc, Pers.
Communie, Duk.	Canchie pundoo, Tel.
Mackoe, Hind.	Anubussaleb, Arab.
	Kaka Machie, Sans.

This is the small black berry of a low growing species of Nightshade: which, although it has been reckoned poisonous in Europe, is eaten by the Natives of India, and as far as Ainslie learned, with impunity. It is sweetish, but not very palatable.—*Ainslie, page* 228.

(7745) SOLANUM OVIGENUM, or Egg plant, is distinguished from *melongena* by its pulpy fruits, which are stated to be narcotic.—*O'Shaughnessy, page* 463.

(7746) SOLANUM PSEUDOQUINA, False Quina Nightshade. Stem shrubby, unarmed

Leaves oblongo-lanceolate, narrow, acute-entire, glabrous above, but with fascicles of villi in the axils of the nerves beneath. Racemes extra-axillary, short; calyx glabrous. This plant is a native of Brazil in the district of Curitiba, in St. Paul without the tropics. The Brazilians use this for the same purposes as the Quina or Jesuit's Bark. It is intensely bitter, and may with advantage be used as a substitute for that bark.

(7747) SOLANUM PUBESCENS, Lin.

Choondaykia or soondaykia TAM.	Woostaykia, TEL.
Shondek pulla DUK.	Katoobie, SANS.

This is about the size of a small marble and grows wild in the woods. It is somewhat bitter and like the Toodoovullay (its congener) is commonly eaten fried, having been previously sprinkled with a little salt and water.—*Ainslie, p.* 238.

(7748) SOLANUM SANCTUM, Palestine Egg-Plant. Stem shrubby, tomentose; leaves ovate-repand, oblique at the base, clothed with hoary tomentum on both surfaces. Berries nearly globose. This plant is a native of Palestine; it is often found in collections of plants. There are several other species of *Solanum*, which, on account of the size, form, and colour of their fruits, are called Egg-Plants as *S. Indicum*, the Indian Egg-Plant, &c.

(7749) SOLANUM SODOMEUM, Sodom Egg-Plant, or Apple of Sodom. Stem shrubby, diffuse; prickles straight, dilated at the base; leaves oblong-sinuate, shining above, and rather scabrous and prickly on both surfaces; lobes obtuse-angular; peduncles bifid. It is a native of the North of Africa and the south of Europe. The Fruit of this plant is white, and about the size of a walnut. It is very subject to the attacks of an insect which deposits its eggs within the germen, and as the fruit enlarges, the larvæ of the insect, as in the case of many other fruits, destroy and pulverise the whole of the interior whilst the rind is left unchanged and entire. When the fruit is gathered under these circumstances, it is crushed to pieces by the hand; or if conveyed to the lips, the mouth becomes filled with an ash-like powder, exceedingly bitter to the taste. To these berries remarkable properties have been assigned by Josephus, Tacitus, and others. Mandeville, an old English writer, says, speaking of the Dead Sea, "And there besyden grown trees that baren fulle faire apples and faire of colour to beholden, butte whosoe breaketh them or cuttethe them in two, he shall find within them coles and cyndres." Milton finely alludes to this fruit in the lines:—

"Greedily they pluck'd
The fruitage fair to sight, like that which grew
Near that bituminous lake where Sodom flamed.
This more delusive, not to touch but taste
Deceived; they fondly thinking to allay
Their appetite with gust, instead of fruit
Chewed bitter ashes."

(7750) SOLANUM TORVUM.

Soonday-kai, TAM.

Used as a vegetable by the natives: a weed.

(7751) SOLANUM TRILOBATUM, Lin.

Moondla moostek-koora. TEL.	Toodoovullay Keeray, TAM.
Achooda, SANS.	

(7752) SOLANUM TRILOBATUM.

Fruit of the Three lobed Nightshade.

Moondlamoostek kai, TEL.	Toovullay kai, TAM.
	Achooda, SANS.

This is round and small being not much larger than a marrow fat pea. It has a somewhat bitter taste not unlike that of its congener the choondaykai, and is commonly eaten fried having been previously sprinkled with a little salt and water.—*Ainslie, p.* 245 *and* 357.

(7753) SOLANUM TUBEROSUM. Common Potato, is known in the genus by its tuberous subterranean stem, herbaceous stems without thorns, unequally pinnate leaves with entire leaflets, and articulated pedicles. It is one of the plants for which we are entirely indebted to America. It is found native in the greatest abundance on the western coast of South America. Like most plants which are much cultivated, an abundance of varieties have been produced from the original plant, and in the leaves, colour of the flowers, shape, size, and colour of the tubers, it has a great tendency to depart from its normal character. Two other species of *Solanum*, namely, *S. Valenzuela* and *S. montanum*, produce edible tubers, but they are little used.—*Eng. Cyc.* In Tenasserim the potatoe is of easy culture, but the tubers are very small, and it is not an object of cultivation, though with a little attention, it might possibly be made one. —*Mason.*

(7754) SOLANUM VERBASCIFOLIUM, Mullein-Leaved Nightshade. Stem shrubby; leaves ovato-oblong, acuminated, entire, tomentose, white beneath, without any leaves in the axils; corymbs nearly terminal, dichotomous; calyx semi-quinquefid. It is a native of Asia, America, and the tropical parts of Australia. This plant is frequently cultivated. Every part is covered with a powdery white tomentum. The flowers are white, and the berries are of the size of small cherries.

(7755) SOLE. PLAGUSIA. TENASSERIM SOLE. A small fish of the sole family that grows to nine inches or a foot long, is sometimes seen in the bazar. It has no pectoral fins, and the dorsal, caudal and ventral fins are united, so it is a species of plagusia. The natives think that two of them always swim together, with their flat, uncoloured sides united. —*Mason.*

(7756) SOLLYA HETEROPHYLLA. PITTOSPORACEÆ. These are ornamental little shrubs with bright blue bell flowers, should be

grown in a loamy soil, and are propagated by seed or cuttings,—*Riddell.*

(7757) SOMRAJ.—Seeds of Conyza (or Serratula) anthelmintica—a worm medicine often sold in the bazar instead of Zeera seeah, or black carraway.—*Ben. Phar.*

(7758) SONCHUS OLERACEUS.

Kaat-mooliugee-keeray, Tam.

The Sow Thistle; used in the Neilgherries as a pot herb by the natives.—*Jaffrey.*

(7759) SONERILA. Perhaps the prettiest little annual in the neighbourhood of Tavoy is a species of Sonerila. Its bright purple blossoms peeping up in the grass attract the attention of the most casual observer.—*Mason.*

(7760) SONF. Indian Fennel. Fœniculum Panmorium.—*Ben. Ph. page* 226.

(7761) SONNERATIA, a genus of Plants belonging to the natural order *Myrtaceæ*, so named by the younger Linnæus in compliment to M. Sonnerat, well known by his 'Voyage à la Nouvelle Guinée,' and his 'Voyages aux Indes Orientales et à la Chine,' and who made known many new plants. The genus is characterised by having a 4-6-cleft campanulate calyx, adhering to the ovary at the very base; petals 4 to 6, alternating with the valvate lobes of the calyx; stamens numerous; styles filiform, with a peltate stigma; fruit baccate, appearing half-superior, many-celled; seeds numerous, nestling in a fleshy pulp, curved: the species form moderate-sized trees, with opposite leaves, which are entire, thick, and almost veinless; flowers usually solitary, large.—*Eng. Cyc.* Dr. Hooker found *Sonneratia*, *Heritiera littoralis*, and *Careya*, forming small gnarled trees on the banks, in the Sunderbuns, with deep shining green-leaved species of *Carallia*, *Rhizophora*, and other Mangroves. Occasionally the gigantic reed-mace (*Typha elephantina*) is seen, and tufts of tall reeds (*Arundo*).—*Hooker, Him. Jour. Vol.* II. *page* 355.

(7762) SONNERATIA ACIDA, is the best known species, being the Pagapate of Sonnerat, and the Blatti of Rheede, which has an acid eatable fruit. The branchlets tetragonal; leaves oval, oblong; calyx 6-cleft; petals 6; berry globose. The tree is forty feet high, and is a native of New Guinea and the Moluccas, as well as of the Malabar coast and of the delta of the Ganges.—*Eng. Cyc.* This abounds in the Tenasserim mangrove swamps, and on the banks of almost every stream on that coast as far as tide-waters reach: the natives use it for various economical purposes, and it is said to be "a better substitute for coal in steamers than any other kind of wood."—*Mason.*

(7763) SONNERATIA ALBA, is a species of the Moluccas, and *S. apetala*, a native of Ava, near Rangoon, as well as in moist situations along the Burmese coast.—*Eng. Cyc.*

(7764) SONNERATIA APETALA. Weeping Sonneratia.

Kambala. Burm.

There is a species of sonneratia in the low wet lands near the mouths of some of the Tenasserim rivers, well deserving of a place in our cities. It bears a strong resemblance to the weeping willow and is one of the most graceful trees in the country. The casuarina has been removed from the coast to our compounds, and the sonneratia is quite as deserving.—*Mason. Sonneratia apetala*, furnishes a strong hard wood of coarse grain, found throughout the Sunderbunds, under the parallel of Rangoon. It is the timber of which boxes for packing beer and wine are made of in Calcutta; gives a red-colored wood, strong and adapted for house-building.—*McClelland.*

(7765) SOOJA. A pickle prepared in Japan from the Dolichos bean.—*Simmonds.*

(7766) SOONDREE. Heritiera Minor. *Syn.* Heritiera fomes. The soondree is a gloomy looking tree that may be distinguished from all others for many miles distant. It is remarkably characteristic of a peculiar soil. Wherever the tides occasionally rise and inundate the land, this tree is sure to be found throughout the whole Tenasserim Coast, but it is never found either on the high dry lands on the one hand, nor in the wet mangrove swamps on the other. It is the tree which was described by Dr. Buchanan Hamilton, who accompanied Symes' embassy, as *Heritiera Fomes.* It is the toughest wood that has been tested in India. When Rangoon teak broke with a weight of 870 pounds, soondree sustained 1312 pounds. It is not a very durable wood, but stands without a rival in strength, although so common on the other Coast, as to give name, as Captain Munro thinks, to the Soonderbunds, yet the tree grows much larger in the Tenasserim Provinces, and affords finer timber.—*Mason.*

(7767) SOONKASOOLA WOOD.

Soonkesooloo, Tel. | Vadee naroinin, Tam.
Sunkesur ke lakree, Hin. |

(7768) SOORINJAN, Hermodactylus. A root in appearance like the pignut, imported via Pali, is bitter and sweet in taste, used as an aphrodisiac.—*Gen. Med. Top. p.* 150.

(7769) SOORIYE. A hard, though somewhat coarse and open grained, heavy Ceylon wood, of a deep chesnut colour.

(7770) SOOT'HNEE. *Duk.* Dioscorea Fasciculata. Yam. Consists of many tubers, about the size and shape of an egg. They are covered with a light coloured thin skin; internally they are white. They are not only eaten, but starch is made from the roots.—*Riddell.*

(7771) SOPHORA, a genus of Plants belonging to the natural order *Leguminosæ*, said to be so named from an Arabic name (Sophera) of one of the species. These are ornamental shrubs and trees, found in central and tropical Asia, also in

the warm parts of North America and the equinoctial and sub-tropical parts of South America. The genus is characterised by having a 5-toothed campanulate calyx; corolla papilionaceous; petals of the keel usually united together at their apex; stamens 10, distinct; legumes moniliform, without joints or wings, and containing several seeds; the leaves are impari-pinnate, usually exstipulate and terminal; the inflorescence is in racemes or panicles of yellow, white, or blue flowers. The species best known in England are *S. Japonica* and *S. Chinensis*, which, being from the northern latitudes of the countries from which they are named, are hardy enough to withstand the climate of England; and it has been proposed to engraft the Nepaul *S. velutina* on the *Japonica*. Being handsome trees, with both leaves and trees differing much from European trees, they are well adapted for standing singly in lawns. They are raised from layers, but also from seeds and require a little protection when young.—*Eng. Cyc.* Wight gives Sophora glauca, 979; heptaphylla, 1155; robusta, 245 and *page* 16 *Vol.* III.

(7772) SORECIDÆ, the family of Shrews, or Shrew-Mice, comprising the genus *Sorex* of Linnæus. This family, according to Mr. Swainson, embraces the Shrews, Moles, and Hedgehogs, with the following characters:—Muzzle lengthened, pointed. Legs short, feeble; feet pentadactylous. Lower incisors generally very long, pointing forwards. No lateral membranes. Mammæ ventral. The family thus characterised includes the genera *Erinaceus*, Linnæus; *Sorex* Linnæus; *Mygale*, Geoff.; *Scalops*, Cuv.; *Chrysochloris*, Cuv.; *Talpa*, Linnæus; *Centenes* Cuv.; and *Condylura*, Desm.—*Eng. Cyc.*

(7773) *Sorex Indicus*, S. MYOSURUS, Pallas, the Musk-Rat of India, has much the same appearance in point of colour and the size of its naked ears as our Common Shrew, but is nearly as large as England's common Brown Rat, and the tail is round and thinly furnished with hairs. This species diffuses a most powerful odour of musk, which impregnates everything that is touched by it. Even the wine in a well-corked bottle, over which the animal has run, is rendered unfit for use in consequence of the flavour imparted to it. Cuvier states that this species is found throughout the East Indies and in a part of Africa, and that it is among the animals embalmed by the ancient Egyptians; but, according to others, it is *S. Olivieri*, Desm., which Olivier found in a mummy state in the catacombs of Sakkara.—*Eng. Cyc.*

(7774) *Mygale moschata, Castor moschatus.* Linn., appears to be the Dæsman of the Fauna Suecica; Le Desman of the French; the Biesamratze of the Germans; the Wychozhol of the Russians; and the Muscovy or Musk-Rat of the English. The tail is shorter than the body, scaly, nearly naked, contracted at its base, cylindrical, and convex in its middle, very much compressed vertically at its extremity; fur brown or dusky above, whitish-ash below. Total length, including the tail, about 15 inches, of which the tail measures 8 inches. It is found in the river Volga, and the adjacent lakes from Novgorod to Saratov. This species does not appear to have been seen on dry land; and indeed it is broadly asserted that it never goes there, but wanders from lake to lake in fortuitous floods only. It is often seen swimming or walking under the water, and coming for air to the surface, where, in clear weather, it is apt to sport.—*Eng. Cyc.*

(7775) SORGHUM, a genus of Grasses, said to be named from the Oriental name of one of the species, of which 'sorgo' is the Italian name. The species have sometimes been referred to *Holcus*, sometimes to *Andropogon*, but from their habit and uses they seem well entitled to be considered as a distinct genus, which may be characterised as having the flowers monœcious, panicled; glume coriaceous, cartilaginous, 2-flowered; the upper flower hermaphrodite, the lower palea more or less deeply bifid and awned between the lobes, the upper often wanting. The species form tall grasses with succulent stems, and are found in the tropical parts of Asia, whence they have spread to the warm parts of Europe.—The species commonly sown in India are *S. vulgare* and *S. bicolor* (Kala-Joar). *S. cernuum* is a distinct species, which forms the principal food of the mountaineers of the Munipoor district. *S. saccharatum* is also cultivated in many parts during the rainy and cold seasons, on land which is too high for rice. The stalks and straw of all are much valued as fodder for cattle, being cut into small pieces, commonly called Kurbee, *Hind.*—*Eng. Cyc.*

(7776) SORGHUM SACCHARATUM. SORGHUM MILLET. A millet plant is occasionally seen, which in the United States is called "broom-corn," it being there manufactured into brooms.—*Mason.*

(7777) SORGHUM VULGARE. HOLCUS SORGHUM. Great Millet. Holcus Saccharatus. Linn. Joar. Guinea Corn.

Sorghum Vulgare is the largest of the small cereal grains, and may be considered the

representative of the Indian Corn (*Zea Mays*) in America, where it is usually called Guinea Corn, and in some works the Great or Indian Millet. The different kinds are usually called Joar in India, where they form a principal object of culture, and one of much more importance than would appear in Europe, as many of the inhabitants live as much upon these small or dry grains as upon rice. The Joar is the Durra of some Arab tribes and the Zurrut of others ; its Indian origin is indicated by the Persian name, Jawur-i-Hindee. It is extensively cultivated throughout Asia, and appears to be the Tall Corn of the Chinese. It has been introduced into the south of Europe, where it is chiefly employed for feeding cattle and poultry, but it is also made in cakes. The flour is white, and a good deal resembles that of the Indian corn in nature.—*Eng Cyc.*

This is largely grown in the Chittledroog and in part of the Nuggur Divisions. It is sown during the thunder showers between the end of April and May ; and the crop is reaped in September and October. The great defect in this grain is that it will not keep, being soon destroyed by insects; and the Ryots have difficulty in preserving sufficient quantity of it for seed on the following year. The seed grain is mixed with ashes, and packed with paddy straw ; in spite of which, however,insects obtain admittance. The stems or straw of this grain when well preserved from rain, will keep for about ten years, and are used as fodder.—*M. E. of* 1857. This millet, of the Linnean genus Holcus, is often grown by the Karens, and occasionally by the Burmese. This is the millet designated in Ezekiel 4. 9.—*Mason.*

(7778) SORREL. This is grown by sowing the seed broad cast and thinning the plants to the distance of eight or ten inches from one another. It may be sown at the commencement of the rains.—*Riddell.*

(7779) SORREL. RUMEX ACETOSA. Used as spinach and salad, of little value, the French Sorrel, R, scutatus is a very delicate vegetable, of easy culture in light soil.—*Jaffrey.*

(7780) SOULAMIA (Soulamion is the name of the tree in the Moluccas), a genus of Plants belonging to the natural order *Polygalaceæ*. It has 5 sepals, the 3 outer ones very small, the 2 inner large and concave; the petal is concave; the capsule samaroid, indehiscent, compressed, corky, emarginate, and 2-celled.—*Eng. Cyc.*

(7781) SOULAMIA AMARA, Bitter Soulamia, is a shrub with crowded ovate leaves tapering to the base, quite entire, and veiny. It is a native of the Moluccas, and has white racemose flowers, the size of those of the vine. The fruit is compressed, thin at the edges, dry, with 2 seeds in each cell resembling cucumber seeds, but smaller, each lying in a small cavity of the cell. —*Eng. Cyc.*

(7782) SOUR SOP. ANONA MURICATA.

(7783) SOUSEE. *Hind.* is manufactured principally in the towns of Tanjore, Trichinopoly, St. Thomé or Mylapore. Those of Tanjore and Trichinopoly are made of silk and mixed with cotton of various colours and sorts ; but Mylapore weavers work only in cotton : they are 7 yards by 1, the silk pieces are sold at from 8 to 20 Rs., those of cotton at 2 to 7 Rs. each. These are used for undergowns, or Lungahs, by the Mahomedan females and as trousers for men.

(7784) SOUTHERNWOOD. ARTEMISIA ABROTANUM. This plant, of the same genus as wormwood, is seen in European gardens in Tenasserim.—*Mason.*

(7785) SOUTHERNWOOD. ARTEMISIA AUSTRIACA. Lin.

Downah, HIND.	Marikolundoo,
Dawanum, TEL.	TAM.

The Tamul people sometimes mix the fine powder of it with Gingilie oil and anoint themselves with it after bathing. The Mahometans prize it for its fragrance as a flower ; and it is one of the many sweet smelling shrubs that are strewed before the Hindoo gods at religious ceremonies.—*Ains. Mat. Med. p.* 44.

(7786) SOY.

Soy. CHINESE.	Soya, JAPANESE.

A peculiar savoury sauce, made from the *Soja*, a species of *Dolichos*, growing in the Eastern parts of Asia. Genuine soy is well flavoured, thick, brown, and clear ; and when shaken in a glass, it should have a coat on the surface of a bright yellowish-brown colour. It is obtained from Canton ; but the best is exported from Japan, by way of Batavia.—(*Waterston*) *Faulkner.* Soy, is made in some parts of the East, from a species of the Dolichos bean (soja hispida) which grows in China and Japan. In Java, it is procured from the Phaseolus radiatus. The beans are boiled soft, with wheat or barley of equal quantities, and left for three months to ferment, salt and water are then added, when the liquor is pressed and strained. Good soy is agreeable when a few years old, the Japan soy is superior to the Chinese. Large quantities are shipped for England and America. The Dolichos bean is much cultivated in Japan, where various culinary articles are prepared from it, but the principal products are a sort of butter termed mico, and a pickle called sooja. 1,108 piculs of soy were shipped from Canton in 1844, for London, British India, and Singapore. 100 jars, or about 50 gallons of soy, were received at Liverpool in 1850. The price is about 6s. per gallon in the London market.—*Simmonds' Commercial Products, page* 313. The best soy is made by boiling beans soft, adding an equal quantity of wheat or barley, and leaving the mass to ferment ; a portion of salt, and three times as much water as beans, are afterwards put in, and the whole compound left

for two or three months, when the liquid is pressed and strained. The flavour and ingredients of soy vary considerably, even among the people who make it, and much of that exported is supposed to be more or less adulterated.—*Williams' Middle Kingdom, Vol.* II. *p.* 402. Leguminous and cruciferous plants ocupy the largest part of the CHINESE kitchen garden; many sorts of peas and beans are cultivated, and the pods and seeds of two species of Dolichos are eaten, and the beans of another species made into soy by boiling and powdering the kernels and then fermenting them with yeast, and mixing other ingredients, according to the taste of the maker or purchaser.—*Williams' Middle Kingdom, Vol.* II. *page* 403. The widely diffused and extensive tribe of Leguminosæ holds an important place in Chinese botany, affording many esculent vegetables and valuable products. Peas and beans form important objects of culture, and the condiment called soy (a word derived from the Japanese soya), is prepared chiefly from a species of Dolichos. One of the commonest modes of making this condiment is to skin the beans, and grind them to flour which is mixed with water and powdered gypsum, or turmeric. The common Chinese eat few meals, without the addition of one form or other of the "bean" curd, or "bean" jelly. One genus of this tribe affords indigo, and from the bunds and leaves of a species of Colutea a kind of green dye is said to be obtained.—*Williams' Middle Kingdom, p.* 283.

(7787) SOYA, or SOWA, Dill Seed, an Umbelliferous Plant cultivated in India. It is the *Anethum Sowa* of Roxburgh, of which the aromatic seed is much used by the natives in cookery, as well as for medicinal purposes; the green parts also are cut down, and sold in the bazars, as the plant is used as a vegetable both by Mussulmans and Hindoos. The seeds are the 'shubit of Avicenna, which is usually translated Anethum; by the Arabs it seems to have been considered the Ἄνηθον of Dioscorides.—*Eng. Cyc. Ben. Ph.* 226.

(7788) SOYMIDA, a genus of Plants belonging to the natural order *Meliaceæ*, named by A. Jussieu from the Telinga name of the tree, which was referred to *Swietenia*, and called *S. febrifuga*, by Dr. Roxburgh. This is a large forest-tree, a native of the mountainous parts of the Rajahmundry Circars, and likewise of the jungly places in general of the central parts of Hindustan. The genus is characterised by calyx 5-leaved, imbricate; petals 5, shortly clawed; stamen-tube cup-shaped, 10-lobed, each lobe bidentate at the apex; anthers 10, included within the tube and lodged between the teeth of the lobes; ovary 5-celled, seated on a broad disc; ovules numerous, pendulous from the centre of the cells; style short, stigma peltate, 5 cornered; capsule woody, 5-celled, 5-valved; seeds winged. The only species known attains a height of 80 feet with abruptly pinnate leaves. The inflorescence is a large diffuse and terminal panicle. —*English Cyclopædia, p.* 859. This tree which is called Rohuna in Hindustan is particularly noted on account of its bark. This is of a dull red colour, of a fibrous nature and astringent and has been much employed in India for the cure of intermittent fevers.—*Eng. Cyc. p.* 859.

(7789) SOYMIDA FEBRIFUGA. *Cedrelaceæ*, Roxb. C. 17. Swietenia febrifuga. *Syn.* Red wood, or Bastard Cedar.

Shem Marum or Choar	Soymeda, TEL.
Kullie Marum, TAM.	Wond Marum, TAM.
Rohuna, Rohitaka, HIND.	

A large forest tree, a native of several of the mountainous districts of India, in the Rajamundry Circars, the district of Cuddapah, the Chunar hills, and the jungles to the south of Hazareebagh. Royle, indeed, states that it occurs in all the central and southern parts of India. The bark of this tree has enjoyed much celebrity. Mr. Breton and others have spoken very highly of the efficacy of this bark in the treatment of periodical fevers. It seems to us to be exactly similar to the mahogany bark, useful where astringent tonics are applicable, but of very questionable efficacy as a true anti-periodic. Although we cannot advise its use in the treatment of obstinate or dangerous cases, still for mild ague, in which doubtless like all other astringent tonics it will often succeed, we commend it to be given in the form of the *extract* described in our officinal preparations.—*O' Shaughnessy, p.* 247-9. This, says Wight, is the Swietenia febrifuga of Roxb. and Ainslie, I have not seen the wood and only know of its existence in Coimbatore from Botanical specimens of the tree brought under that Native name. The wood is said to be most durable and strong.—*Wight. Soymida or Swietenia febrifuga*, is very abundant in Nagpore and Southern India. Rohun bark is an undoubted febrifuge, but in the bazars in Bengal, Nux Vomica bark is often sold for it, and from this Mr. Piddington, who has shown much zeal in examining native febrifuges, procured a salt, which Dr. O'Shaughnessy found to be one of Brucine. Dr. O'Shaughnessy has never succeeded in obtaining an alkaloid from the tree Rohun, which it may be observed is of a dull red colour, with rough grey epidermis, and yields a red powder. The value of this bark as a febrifuge has been attested by Roxburgh, Duncan, Breton and Spilsbury. Dr. O'Shaughnessy does not think so highly of this bark as others do, not considering it much superior to that of its congener, Mahogany. He accounts it useful where astringent tonics are applicable, but of very questionable efficacy as a true antiperiodic; he thinks it may succeed where other astringent tonics will do so. From the reports of dispensaries I am inclined to have a somewhat higher opinion of this medicine and

believe that it is of considerable use, though by no means equal to the Berberis. If the statement of the Madras report be accurate, its virtues may be more powerful than is supposed. The reporters say, "We have from our own experience found that when taken beyond the quantity of 5 or 6 drachms in the course of the day it produced vertigo and other head symptoms." This is confirmed by Dr. Spilsbury, who says large doses were found to produce vertigo.—*Ind. Ann. Med. Sci. for* 1856. *p.* 191.

(7790) SPARIDÆ, or SPAROIDES, a family of Fishes belonging to the section *Acanthopterygii*, which are distinguished by the following characters combined, namely: the possession of a single dorsal fin, the anterior half of which is supported by spinous rays, and which is not divided, nor is it protected by scales; the operculum is spinous, the palate destitute of teeth, the branchiostegous membrane has five or six rays, and the pyloric appendages are few in number. The body is usually of an ovate form and covered with large scales; the mouth is not protractile. The species of this family feed chiefly upon the animals of small shell *Crustaceæ* &c., for crushing which their strong teeth are admirably adapted.

The genus *Pentapus* is founded upon certain Sparoid Fishes found in the India Seas, and off the coast of Australia, which approach the genus *Dentex*, but have two strong canine teeth in front of each jaw, between which sometimes are two or four much smaller teeth; the other teeth are minute, prickly, close together, and arranged in a sigle row in each jaw.

Lastly, the genus *Crenidens* is distinguishable by the foremost row of compressed teeth being dilated at the apex and notched; behind these are numerous small globular teeth There is but one species, the *C. Forskalii*, Cuv. and Val., an inhabitant of the Red Sea.—*Eng. Cyc.*

(7791) SPARAXIS. IRIDEÆ. This is a pretty species of Irideæ, and is cultivated by dividing the roots.—*Riddell.*

(7792) SPATHE (the Greek σπάθη). This term is applied to the sheathing involucrum of many plants. It is seen in the greatest perfection in the flowers of *Palmaceæ* and *Araceæ*, where, during the flowering of the plants, it embraces the entire inflorescence. This organ is considered by most botanists to be a modification of the bract.—*Eng. Cyc.*

(7793) SPATHIUM CHINENSE. SPATHIUM ROOT. In Tenasserim there are one or two species of Spathium, plants that grow in the water; one of which Voigt says, is found on the banks of the Irrawaddy, and has roots "nearly as good as potatoes."—*Mason.*

(7794) SPATHODEA, a genus of Plants belonging to the natural order *Bignoniaceæ*. The calyx is spathaceous, cleft and toothed or entire on the other side; the corolla is funnel-shaped, with a 5-lobed rather unequal limb; the four stamens are divided into two long and two short, with the additions of a fifth sterile filament; the capsule silique-formed, falcate, falsely 4-celled, and corky; the seeds are furnished with membranous wings; the species are erect shrubs or trees, rarely climbing shrubs; the flowers, somewhat panicled, orange colored, yellow, or purple. Dr. Wight gives Spathodea arcuata, 1340; and Rheedii, 1339.

(7795) SPATHODEA ADENOTHYLLA. A small introduced tree. Madras Hort. Garden. 53.

(7796) SPATHODEA ARCUATA. *Bignoniaceæ*, Icon. 1340.

Rau pallay marum, TAM.

A medium sized tree frequent in the Walliar jungles. I do not know the wood, but judging from its relations—padre and vadencoornee—I infer it will be found good.—*Wight.*

(7797) SPATHODEA LONGIFLORA, is an arboreous plant, and has large spreading terminal panicles, a bilabiate corolla, long pendulous slender sub-cylindrical follicles, with sharp edges and variously curved; the flowers are large yellow, and very fragrant; the follicles very long; the wood of this tree is high-coloured, hard, durable, and of much use amongst the inhabitants of the hills about the coasts of Coromandel and Malabar, where it is plentiful.—*Eng. Cyc.*

(7798) SPATHODEA RHEEDII has downy impari-pinnate leaves, roundish downy leaflets, terminal erect racemes, and a much-curved slender corolla; the shoots are covered with a whitish down; the racemes the length of the leaves; the flowers white and pretty large; the limb spreading; the fruit about a foot long, pendulous, twisted in various forms.—*Eng. Cyc.*

(7799) SPATHODEA ROXBURGHII has its leaves three in a whorl or scattered impari-pinnate; the leaflets from 4 to 5, in pairs serrated and smooth; the panicles erect, terminal, dense, downy, and many-flowered; the fruit narrow and 4-celled; the calyx generally 2 parted, with the upper lip 2-cleft and downy. It is a native of the Circars. The branches are very spreading; the back gray, with a few scabrous spots; the flowers large, rose-coloured, and delightfully fragrant; the limb of the corolla nearly equal, and elegantly waved at the edges. This species is remarkable on account of its serrated leaves. The wood is employed for many purposes by the natives.—*Eng. Cyc.*

(7800) SPATHODEA UNCINATA. BIGNONIACEÆ.—This genus of plants are showy and handsome, the colour of the flowers being yellow, purple, and red; they are easily propagated by seed or cuttings, and require a good garden soil.—*Riddell.*

(7801) SPATTALLA. PROTEACEÆ.—This genus are all Cape plants, and require the same treatment as others Proteaceæ.—*Riddell.*

(7802) SPEAR-MINT. Mentha viridis. Cultivated for the fragrant leaves, which are used in sauces, tea, &c., requires rich soil, shade and plenty of water, propagated by division of the plant.—*Jaffrey.*

(7803) SPELTER, ZINC, TUTENAGUE.

Pi-yuen, CHIN.	Dasta, NEP.
Zinc, FR.	Jussud, PERS.
Zink, GER.	Schpiauter, RUS.
Sungbusrie, DUK.	Zinco, Cinck, SP.
Jussud, GUZ. HIND.	Tootoo nagum, TAM. and TEL.
Zincum, LAT.	
Zinco, IT.	

A metal of a blueish-white colour and lustre. Being cheap, light, and a metal which, when superficially oxidized, long resists the further action of air and water, it is now employed as a substitute for lead in lining water cisterns and roofings: alloyed with copper it forms brass; and several of its compounds are used in medicine. Zinc is obtained either from *Calamine*, a native carbonate, or *Blende* a native sulphuret: it has never been found in a state of purity. Localities, Great Britain, China, Germany.—*Faulkner. Spelter*, is in China used in the manufacture of brass; it is in plates of half an inch thick of a whitish-blue color. There was formerly a monopoly of spelter, so that no foreigner could either buy or sell it; the consumption may perhaps increase a little under the new arrangement, but the native tutenague and white copper will probably prevent much consumption of foreign spelter.—*Morrison.*

(7804) SPERMACETI.

Blanc de Baleine, also Sperme de Baleine, FR.	Spermaceti IT.
Wallrath, GER.	Spermazet RUS.
	Esperma de Ballena. SP.

The produce of a species of whale *Physeter macrocephalus*, found chiefly in the South Seas. It is characterised by a large head, great part of which is occupied by a triangular cavity filled with a white oily substance, which, after its death congeals into an unctous mass, and from which a considerable quantity of oil may be obtained by expression. The residuum is a concrete fatty substance called spermaceti, which, after being purified, is cast into blocks or cakes. These are of a white colour, have a peculiar lustre, are transparent, brittle, smooth, but not greasy; smell-peculiar, but weak. Spermaceti burns with a brillant flame, without smell; and is used in the manufacture of candles; also for medical purposes.—*Faulkner.* The *Physeter macrocephalus*, called the Cachalot, or White Whale, is of immense size, frequently 60 or more feet in length, of which the head constitutes one-third. This part is the chief reservoir of the spermaceti, which however is found in several other parts of the body, mixed with the sperm oil. It is mostly lodged in two large cavities of the upper jaw, one above and the other below, divided from each other by the nostrils. These cavities are subdivided into numerous cells of unequal size by ligamentous or tendinous partitions; these partitions are of the same nature as those which separate the fat in other animals, but, owing to the great size of the creature, of a larger and stronger kind. The purest spermaceti is contained in the largest and least ligamentous cells. The part in which it is lodged is quite distinct from the cranium containing the brain, which spermaceti was at one time supposed to be. During the life of the animal the spermaceti is in a fluid state, and on the head being open has the appearance of an oily clear white liquid. On exposure to the air the spermaceti concretes and deposits from the oil. They are then separated, and put into different barrels.—*Eng. Cyc.*

(7805) SPERMACETI-WHALE. CETACEA.

(7806) SPERMADICTYON, a genus of Plants belonging to the natural order *Rubiaceæ*, named from σπέρμα, seed, and δικτυον, a net, from the manner, in which the seeds cover the placenta. The genus is characterised by having the calyx-tube ovate, 5-partite, persistent: corolla densely pubescent; tube long, straight, 5-lobed; stamens 5, included within the corolla-tube; stigma 5-cleft; capsule crowned by the calyx, contains 5 nuts. The species form shrubs, with white and light blue very fragrant flowers, with leaves lance-shaped, shortly petioled; stipules short. They are natives of Hindustan. *S. suaveolens*, the *S. Hamiltonia* of Roxburgh, ascends the Himalayas to elevations of 3000 feet, and has been cultivated in Great Britain as a stove-plant.—*Eng. Cyc.*

(7807) SPHENOCLEA, a genus of Plants belonging to the natural order *Campanulaceæ*, consisting of only a single species. The genus is characterised by having a superior 5-parted calyx with inflexed segments. Corolla 5-parted, with the segments inflexed and somewhat auricled at the base, and which conceal the 5-sessile stamens; ovary inferior; style very short and 2-lobed; capsule membranous, many-seeded, with a central fungous placenta, circumsessile; seeds minute, embryo without albumen, straight, with the radicle next to the hilum. The only known species, called *S. Zeylanica*, is an annual, with alternate entire leaves, without stipules; found in marsh situations in all parts of India. It is sometimes made the type of an order.—*Eng. Cyc.*

(7808) SPHÆRANTHUS. Of this genus, Wight gives Sphæranthus amaranthoides, 1149; and hirtus 1094.

(7809) SPHÆRANTHUS INDICUS. INDIAN SPHÆRANTHUS.

Kottangkarundei, TAM.	Bodatarum, TEL.
Moondie, DUK.	Moondee, SANS.
Dookkon, ARAB.	

The small oblong seeds and receptacles of this low growing herbaceous plant (2) are reckoned by the Vyteans amongst their anthelmintics and are prescribed in powder. Rheede tells us that the powder of the root is considered as stomachic, and that its bark ground small, and mixed with whey, cures the piles.—*Ains. Mat. Med. p.* 85.

(7810) SPHÆRANTHUS MOLLIS: Soft. Globe Flower.

Gork-mundi. Hind.

Common near the Ana-sagur; used by the natives in medicine.—*Genl. Med. Top. p.* 135.

Sphæranthus Mollis and Indica, are common near water banks at Ajmeer: S. mollis has a round pink blossom: considered heating: cleanses the blood: aphrodisiac: also opens the bowels: the flower and seed capsules are used.—*Genl. Med. Top. p.* 206.

(7811) SPHÆROCARYA, a genus of Plants belonging to the natural order *Rhamnaceæ*, so named from σφαιρα, a sphere, and καθυον, a nut. The species forms moderate-size trees in Nepaul. The clayx is 5 parted. Petals 5 and alternate with the 5 stamens, which, like the petals are inserted into the clayx, and with 5 fringed scales placed between the stamens, and opposite the calycina segments. Drupe pear-shaped, containing a smooth round nut.—*Eng. Cyc.*

(7812) SPHÆROCARYA EDULIS, is so called from its fruit being eaten and relished by the Nepaulese, though not very palatable to a European taste. This tree is a native of the forests of Nepaul, and has alternate, ovate-entire, exstipulate leaves, with axillary and terminal villous racemes of small greenish-coloured flowers, which are without odour.—*Eng. Cyc,*

(7813) SPHÆROCOCCUS, a genus of plants belonging to the natural order *Algæ*. It was formed by Stackhouse, and applied to the plants belonging to it, on account of their globose fructification. A great number of species of this genus have been described including amongst them some of the most useful of the sea-weed tribe. These species have been distributed by later botanists into the genera *Rhodomenia, Gigartina, Chondrus*: *Gelidium*, and *Phyllophora* and the genus *Sphærococcus* has only one species, the *S. coronopifolius*. The genus *Chondrus* affords the Carrageen Moss, which is so much used as an article of diet. It is a species of *Gelidium*, with which, as some assert, the swallows build their nests in the Eastern Archipelago and which are so highly valued as articles of food by the Chinese.—*Eng. Cyc.* The gelatinous substance of which the nests are composed, however, seems, really, to be a natural secretion from the swallow itself.

(7814) SPICES.

Specerye, Dut.	Spezj, Spezierie, It.
Epiceries, Epices, Fr.	Especiaria, Port.
Spezereyen, Ger.	Pranue korenja, Rus.
Gurm-mussala, Guz. Hind.	Especias, Especerias. Sp.

Under this denomination are included all those vegetable productions which are fragrant to the smell, and pungent to the palate: such as cloves, ginger, nutmegs, cinnamon, allspice, cardamoms, &c.—*Faulkner.* Spices and condiments are largely employed by the people of India. Some are imported and many of them are exported to a considerable extent. They are obtained from the barks, the dried seeds, the fruit, flower-buds, and root-stocks of different plants. The chiefly aromatic barks are the Cinnamon and Cassia lignea; the seeds and fruits include Pepper, Cardamoms, Coriander, Cummin seed, Star anise, nut-megs and chillies. The flower buds of some furnish cloves and cassia buds, and the roots supply ginger, and turmeric. The English and botanical names of the principal of the series are given below, and their descriptions will be found under their several heads.—*Madras Exhibition of* 1857. *English Cyclopædia, Simmonds.*

Areea or betle nut,	Areca catechu.
Betle leaf or pan,	Piper betle.
Cassia bark, ...	Laurus cassia.
Cassia buds, ...	Cinnamomum iners.
Cinnamon, ...	Cinnamomum aromaticum.
Cloves,...	Eugenia caryophyllata.
Mace & nutmegs,	Myristica moschata.
Cardamoms, ...	Elletaria cardamomum.
Do. wild,...	
Pepper, ...	Piper nigrum.
Do. long,...	Piper longum.
Chillies, ...	Capsicum, (var. sp.)
Ginger, ...	Zingiber officinale.
Turmeric, ...	Curcuma longa.
Coriander, ...	Coriandrum sativum,
Cummin, ...	Cuminum cyminum.
Mustard, ...	Sinapis, (var. sp.)

(7815) SPIDER-WORTS. Several species of spider-worts are abundant in Tenasserim. One *Commelyna cæspitosa*, a creeping species of commelyna may be often seen trailing up the sides of fences. Another with blue flowers like the former, but with a different habit, is sprinkled among the grasses at almost every door. The latter belongs to the genus aneilema, *Aneilema herbacceum*. There are also one or two other species common, but I do not find them described.—*Mason.*

(7816) SPIGELIA, a genus of Plants belonging to the natural order *Spigeliaceæ*. It is commemorative of Adrian Spigelius. The characters of this genus are:—Calyx 5 parted; corolla funnel shaped, with a 5 cleft equal limb; anthers converging: capsule didynamous, 2-celled, 4-valved many-seeded. This genus consists of annual and perennial herbs, and under shrubs with opposite leaves and rose coloured or purple flowers. They are natives of North and South America, and are found in various soils.—*Eng. Cyc.*

(7817) SPIGELIA MARYLANDICA. Carolina Pink, Pink Root, India Pink. A peren-

nial, herbaceous, medicinal plant, (*S. Marylandica*), a native of S. America. The part chiefly valued is the root, which, in its newly dried state, is celebrated as an anthelmintic. It has a bitter nauseous taste, and a tea-like smell.—*Faulkner.*

(7818) SPIKENARD.

Sunbul-ul-Teeb, ARAB.	Jettamassie. TEL.
Bal-chur, BENG. HIND.	Narden also Nardos, GREEK.
Jettamansi, Chebur, GUZ.	Nardoom, LAT.
Sattamansi, SANS.	
Shad-a-mangie, TAM.	

The root is of a blackish colour, and resembles the bushy tail of the Ermine. Its odour is strong and fragrant; and it is much esteemed by all Eastern nations. The plant is a native of the mountains of the north of India, at very great elevations; and the roots are also brought to India from the Persian Gulf.—*Faulkner.* Spikenard is a substance which has enjoyed celebrity from the earliest period of the world's history, and has engaged the attention of numerous commentators on the works of the ancients, as well as of some modern authors. It is interesting therefore not only as making us acquainted with one of the substances known to and esteemed by the Greeks and Romans, but it is important likewise as being mentioned in the Bible, since the Nard of Scripture is supposed to be the same substance as the Nardos of the ancients called also *Nardostachys* (ναρδόσταχυς) and hence Spikenard, the word Stachys being rendered by the word Spike. Dioscorides, in the first chapter of his first book, treats of the various aromatic and stimulant substances which were known to the ancients, and among these of the various kinds of Nard. Of the first kind, called simply Nardus (νάρδος), there are two varieties, the one Syrian, the other Indian; the former so called, not because it comes from Syria, but because the mountains in which it is produced have one part turned towards Syria and the other towards India. This may refer either to the Hindu-Kush, or to so many Indian products finding their way to Syria, by the way of the Red Sea and the Euphrates, from the earliest times. The other variety is called Gangitis from the river Ganges, near which, while flowing round a mountain, it is produced, bearing many hairy spikes from one root. These are strong-smelling, but those growing in moist situations less so than those found on the mountains. One variety, he further says, is called Sanphariticon, from the name of a place. This first kind being called Nardus, and distinguished into the Syrian and Indian varieties, the second kind he calls Celtic Nard (νάρδος Κελτική), and the third kind a Mountain Nard (νάρδος ορεινή) On consulting Avicenna, we are referred from Narden to Snubul, pronounced Sumbul, and in the Latin translation from Nardum to Spica, under which the Roman, the mountain, the Indian, and Syrian kinds are mentioned. This proves, as has been already stated by Sir William Jones, that Sumbul, &c, was always considered by Arabian authors as synonymous with the Nardos of the Greeks. In Persian works on Materia Medica, all translated from the Arabic, as, for instance, the 'Mukhzun al-Adwieh,' or 'Magazine of Medicines,' we have four different kinds of Sunbul:— 1, Sunbul Hindee; 2, Sunbul Roomee, called also Sunbul Ukletee, and Narden Ukletee, evidently the above Celtic Nard, said also to be called Sunbul Italion, that is, the nard which grows in Italy; 3, Sunbul Jibullee, or Mountain Nard: hence it is evident that the kinds described by Dioscorides are alluded to, and in fact the accounts given are merely translations of his descriptions. The fourth kind of Sunbul appears to be a hyacinth or polyanthus. But the first is that with which alone we are at present concerned. The synonyms given to it are—Arabic, Sunbul-al-Teeb, or Fragrant Nard; Greek, Narden; Latin, Nardoom, and Hindee, Balchur, and Jatamansee. Having the Hindee and Sanscrit names of an Indian plant, the next step was to obtain it. This was first attempted by Sir William Jones, at a time when we had no access to the Himalayan Mountains, and a wrong plant was sent him. Dr. Royle informs us that on making inquiries on the subject, when at Saharunpore, in 30° N. lat., about 30 miles from the foot of the Himalayas, he learnt that Jatamansi, better known in India by the name Bal-Chur, was yearly brought down in considerable quantities from the mountains, such as Shalma Kedarkanta, near the Ganges and Jumna rivers, to the plains. Having obtained some of the fresh brought down roots, he planted them both in the East India Company's Botanic Garden, and in the mountains, in a nursery attached to it. The plant produced was found to belong to the natural order *Valerianaceæ*, and has been named *Nardostachys Jatamansi* by De Candolle, and formerly *Patrinia Jatamansi* by Mr. Don, from plants sent home by Dr. Wallich, from Gossainthan, a mountain of Nepal. Mr. Don obtained the additional corroboration that Spikenard bought in a chemist's shop by this name exactly corresponded with the roots of the Jatamansi.' (Royle, 'Illust. Himalayan Bot.,' p. 242.) Hence there can be no doubt that the Nardos described by Dioscorides is the Jatamansi of the Hindoos, and probably the same substance which has been mentioned by such writers as Hippocrates; and there is nothing improbable in its being the Nard of Scripture, and it has been shown to be a plant belonging to the natural order *Valerianaceæ*. It is curious that the Celtic and mountain nards are also Valerians, the former being yielded by *Valeriana Celtica* and *V. Saliunca*, still exported from the mountains of

Austria to Egypt, whence it has spread into both Africa and Asia, being valued for its fragrance, and hence employed in perfuming baths; and the other by *V. tuberosa*. Dr. Royle mentions it as a curious coincidence, if not allowed to be a sign of accurate knowledge, that the Persians should translate the φυ of Dioscorides, which he also calls Wild Nard, Foo of the Arabians, by the term Bekh-i-Sunbul, Root of Soonbul. The plant correctly ascertained by Sipthorp has been named by him *Valeriana Dioscoridis*.

(7819) SPILANTHES ACMELLA. This species of spilanthes is planted by the natives of Tenasserim for its medicinal properties.—*Mason*,

(7820) SPINACIA, a genus of Plants belonging to the natural order *Chenopodiaceæ*. This genus is dicœcious, the male and female flowers being on different plants; the male flowers are composed of a calyx, with 5 deeply cloven concave oblong obtuse segments; 5 stamens, with filaments longer than the calyx, with oblong double anthers. The female flowers have a monosepalous calyx, with four divisions, two of which are smaller and opposite; a superior ovary with 4 styles and simple stigmas. As the fruit ripens the calyx hardens and adheres to it. The ovary contains a single seed. There are only two species, which are herbaceous plants with alternate leaves, and axillary flowers of a green colour.

(7821) SPINACEA OLERACEA, The Common Spinach.

Vusayley-keeray, Tam.

Is well-known on account of its use in the kitchen. It has an herbaceous stem one or two feet high, branched, and hollow; arrow-shaped leaves; male flowers in long spikes, abounding with pollen; female flowers on another plant, axillary, herbaceous, and small. The fruit is a small round nut, which is sometimes very prickly.—Both Spinacea oleracea and New Zealand spinach are commonly cultivated in all gardens.

Spinach is used as a culinary vegetable. It grows in rich soil, requires plenty of water, should be sown thinly in drills or broad cast every month or six weeks, may be had during the hot months in sheltered situations, with attention to water.—*Jaffrey*.

(7822) SPINACIA TETRANDRA.

Choolaee, Hind.

This Hindustanee name is indifferently given to Spinacia Tetrandra, Tetrandous Spinach and Amarantus polygamus. The former is a common sort of native greens, and, when boiled, resembles spinach; it is procurable nearly all the year round. The latter is much cultivated by the natives. It is sown broad-cast in beds from June to March. The leaves are sold in the bazar at one pice the seer. Used as a greens and also in curries.—*Riddell, Jaffrey*.

(7823) SPINAGE, NEW ZEALAND. Is a hardy annual, with fleshy leaves and numerous branches. As a spinage it is as valuable as the Orache. If watered, grows freely, and produces leaves in the hottest weather.

(7824) SPINEL occurs crystallized either in regular octahedrons, or in macles presenting different forms. It is of various shades of red, violet, or yellow, more rarely black. By lapidaries, the scarlet coloured, is termed *spinel ruby*; the rose-red, *balas ruby*; the yellow or orange red, *rubicelle*; and the violet-coloured, *almandine ruby*. The first is the most valuable. Spinel is not so hard as the oriental ruby; and is readily distinguished both by its colour and crystallization. Principal localties Sweden, Ceylon, Malay Peninsula.—(*Waterstone*) *Faulkner*. According to the English Cyclopædia *Spinell Spinell Ruby, Balas Ruby Ceylanite Candite* &c., is a Mineral occurring in loose and imbedded octohedral crystals. Primary form the cube. Cleavage easy, parallel to the faces of the octohedron of the black opaque variety; difficult in the other varieties. Fracture conchoidal. Hardness greater than that of quartz, but less than that of corundum. Colour red, blue, violet, green, yellow, brown, and black. The first is the most common. Streak white. Lustre vitreous. Transparent, translucent, opaque. Specific gravity 3·5 to 3·7. Infusible by the blow-pipe; the red varieties are rendered black and become opaque by exposure to it, but on cooling, at first of a fine green by transmitted light, then nearly colourless, and at last become again red. Spinell is found in Ceylon and Siam in isolated and rolled crystals in the beds of rivers. It is found embedded in carbonate of lime in North America and Sweden. Several varieties have been analysed; red transparent spinell by Vauquelin; blue, by Berzelius; green and black, by Dr. Thomson:—

	Red.	Blue.	Green.	Black

(7825) SPIRÆA, a genus of Plants belonging to the natural order *Rosaceæ* tribe *Spiraceæ*. The name occurs in ancient authors, and is supposed to be derived from σπεῖρα, a cord, in allusion to the fitness of the plants for twisting into garlands. The genus is diffused through the temperate parts of the northern hemisphere, and is characterised by having a 5-cleft permanent calyx; stamens 10 to 50, inserted in a torus with the 5 petals, which are inserted into the calyx; carpels sessile, solitary or several rarely connected into a capsule; seeds 2-15, pendulous,

very rarely ascending. The species, upwards of 50 in number, form small unarmed shrubs or perennial herbs; leaves usually simple, sometimes pinnately cut; flowers white or reddish. They are found in Europe, North America, Siberia, China, and the Altai and Himalayan Mountains. —*Eng. Cyc.* Fortune mentions amongst Chinese shrubs the *Spiræa callosa* and *Spiræa Reevesiana*.

(7826) SPIRITS.

Daroo Guz. Hind. | Shurab, Pers.

All inflammable liquids obtained by distillation, as brandy, rum, geneva, whiskey, &c, are comprised under this designation.—*Faulkner*.

(7827) SPOGEL SEED. PLANTAGO ISPAGHULA.

Ispagool, Pers.	Esubgool, Ispagool, Duk. Guz. Hind.
Buzr kaloona, also Buzra-kotuna, Arab.	Fusliioon, Greek.
	Ispoghul Verei, Tam.

The seed of a plant (*Plantago Ispaghula*), grown in the upper provinces of India, Guzerat, Persia, &c. The seeds are of a very cooling nature, and form a rich mucilage with boiling water, which is much used by native practitioners, and occasionally by European medical men in India, in cases with inflammation of mucous membranes. The seeds met with in Bombay are brought from the Persian Gulf, Guzerat, and Sonmeeanee.—*Faulkner*. In India the Plantago Ispaghula is cultivated during the cold season for the seeds, which are used as an emollient and light article of diet for convalescents —*O'Shaughnessy, page* 510. In making a decoction of Ispaghool take of Ispaghool seeds two drachms, distilled water one pint. Boil and strain: this preparation is a simple demulcent. That of Ispaghool is used in dysenteries, and recommended by Mr. Twining.—*Bengal Phar. p.* 277.

(7828) SPONDIACEÆ, a natural order of Plants belonging to the Syncarpous group of Polypetalous Exogens. It has unisexual flowers; a 5-cleft regular calyx; 5 petals, inserted under the disc; 10 perigynous stamens arising from the same part as the petals; superior sessile ovary, 25-celled, with 5 very short styles and obtuse stigmas; one ovule in each cell. Fruit drupaceous. Seeds without albumen. The plants of this order are trees without spines, having alternate unequally pinnate leaves without pellucid dots. The flowers are arranged in panicles or racemes. This order was formerly included in *Terebinthaceæ*, but has been separated by Kunth and Lindley, on account of their syncarpous fruit and the absence of a resinous juice. The real affinity of *Spondiaceæ* appears to be with *Aurantiaceæ*, from which they differ in little beyond their perigynous stamens and the absence of dots on their leaves. They are natives of the West Indies, the Society Islands, and the Isle of Bourbon. The fruit of some of the species of *Spondiaceæ* is eatable, and is known in the West Indies by the name of Hog-Plums. —*Eng. Cyc.*

(7829) SPONGIA, the generic name under which Linnæus and many subsequent systematists have ranked the very numerous forms of organisation analogous to the sponges of commerce. Generally, and we think justly, zoologists have claimed these organisations for the animal kingdom, and ranked them among the *Zoophyta*; but there are eminent writers who dissent from this view on different grounds, and prefer to rank the marine and freshwater sponges with plants. For in regard to their constituent structure, they are composed, as so many of the *Polypifera* are, of a firm horny or stony skeleton immersed in a soft gelatinous living mass: in respect of the aspect of these two substances, the resemblance which they offer to *Alcyonia* appears very strong, with their external forms, uncommonly varied, sometimes resemble *Alcyonia*, often approach to *Palmipora*, frequently to *Pavonia*, *Agaricia*, and other forms of Lamelliferous *Zoophyta*. The currents of water which pass through the canals of their substance are analogous to many operations among *Polypifera* and *Mollusca*, and depend on similar ciliary organs, which have been detected in situ in *Grantia ciliata*. As however they contain no *Polypi*, it is difficult to rank them under the *Polypifera*. Dr. Johnson omits, in his excellent work on British *Zoophyta*, the sponges; and the following summary of his reasons deserves attention:— "If they are not the productions of Polypes, the zoologist who retains them in his province must contend that they are individually animals, an opinion to which I cannot assent, seeing that they have no animal structure or individual organs, and exhibit no one function usually supposed to be characteristic of the animal kingdom. Like vegetables, they are permanently fixed; like vegetables they are non-irritable; their movements, like those of vegetables, are extrinsical and involuntary; their nutriment is elaborated in no appropriated digestive sac; and, like cryptogamous vegetables or algæ, they usually grow and ramify in forms determined by local circumtances, and if they present some peculiarities in the mode of the imbibition of their food, in their secretions, yet even in these they evince a nearer affinity to plants than to any animal whatever." On this we may remark, that very many animals are as permanently fixed as sponges; that irritability is not to be looked for in every part of a sponge any more than in a *Rhizostoma*, whose divided digestive cavities are very unlike ordinary stomachs; and that the forms of sponges include remarkable analogies with the supports of *Polypi*. It is to our countrymen Ellis and Grant that the history of sponges is most indebted. The

former established the existence and nature of the currents of water which pass through the substance; and the latter, besides confirming the results of Ellis, added a vast quantity of new and valuable observations. Mr. Bowerbank has contributed precise information regarding both the fossil and recent sponges. (Ellis, 'On Corallines;' Grant, 'On Sponges,' in 'Edinburgh Philosophical Journal;' Bowerbank, 'Geological Proceeding,' 1840; and 'Microscopical Journal,' 1841.) Sponges may be thus characterised:—They consist of an albuminous skeleton and gelatinous matter, forming a mass not irritable, with numerous holes, connected internally with anastomosing canals. The skeleton is either simple, consisting of horny fibres, as the species so commonly used for domestic purposes; or compound, being strengthened by calcareous or siliceous spicula. Some of the skeletons of sponges are entirely horny; others are entirely siliceous; some are entirely calcareous; but the greater number are compound, and consist of horny matter with additions of spicula in various proportions. The gelatinous matter, abounding in horny matter and transparent globules, connects the different parts of the skeleton and membranes, lines the various canals, and forms the margins of the openings. The pores are minute openings (on the surface) with a gelatinous margin, strengthened or defended by the skeleton or specula, into which the water enters in currents, generated probably by a ciliary apparatus, which, however, has not yet been detected by the microscope, except in *Grantia ciliata*. The water, after traversing the interior canals, is ejected by means of orifices which are larger than the pores, and in many species are elevated above the surface in the form of tubular prolongations of the canals. The ova are numerous, at first appearing like groups of minute, irregularly shaped opaque granules, derived from the gelatinous matter, which unite into ovate bodies, falling at maturity into the canals, and are expelled by the orifices. These ova float in the water, and exhibit spontaneous motion by the rapid action of the cilia, which cover the anterior portion of the body, at length attach themselves, and then expand into the forms of maturity. The currents from the orifices are best examined by placing the recent animal in a shallow dish of water, and throwing a little powdered chalk on the surface, the motion of which will indicate the direction of the streams. For the purpose of examining the skeleton, it is requisite to macerate the sponge in hot water, which removes the gelatinous matter, and leaves the skeleton in a state fit to be examined under a microscope. When the spicula are siliceous, the animal matter may be removed by nitric acid, or by combustion, as was practised by Müller ('Zool. Dan,' t. 85), when the vitreous needles will appear unaltered. The gelatinous substance of sponges is scarcely capable of conservation. It is usually of a ropy consistence, sliding off from the skeleton, or else pressed off by the divers for sponge. It is of various colours, but commonly fawn-coloured; or orange-coloured; in this respect resembling the gelatinous parts of *Polypiaria*. Horny Sponges with anastomosing fibres, fit for domestic use, belong mostly to warm zones of the sea; sponges with calcareous spicula are rather numerous on the British coasts; and siliceous spicula are common in the sponges of most latitudes [SPONGIADÆ.] Remains of both horny and spicular sponges occur in a fossil state.—*Eng. Cyc.*

(7830) SPONDIAS ACUMINATA.

Ambut, DUK.

A middle-sized elegant tree, with shining leaves; fruit the size of a small egg.—*Riddell.*

(7831) SPONDIAS DULCIS. The Otaheite apple, much cultivated in the Society Islands. Introduced into Bombay.—*Riddell.*

(7832) SPONDIAS MANGIFERA.

Mirreymangi-kai, TAM.
Ambalam, RHEED. HIND. and BENG.
Ambara also Amra, TEL.
AMATAM.

The Hog-plum. The leaves of this tree are used in the preparation of chatnies. The green fruit used as pickles.—*Jaffrey.* The hog plum is a large tree with pinnate leaves; deciduous in the cold weather; they have a peculiar smell when bruised: the fruit is acid, and only used in curries.—*Riddell. Spondias Mangifera* is cultivated generally by the Burmese in groves near large towns. The tree grows to a considerable size and yields abundant seed.—*McClelland.* Hog's plum, is an intensely astringent fruit very appropriately named. The Karens have a tradition that in those Golden Days when God dwelt with men, all nations came before him on a certain day, each with an offering from the fruits of their land, and the Karens selected the hog's plum for their oblation; which gave such offence, that God cursed the Karen nation and placed it lowest among all the nations by whom they are surrounded.—*Mason.* The wood of this tree is soft and of little if any use. From wounds made in the bark at the beginning of the hot season very large quantities of transparent juice issue, which soon hardens into a mild insipid gum very like gum arabic. The fruit is eaten raw when ripe, and before ripe is pickled, put into curries, made into tarts &c.—*Rhode, M.S.S.*

(7833) SPONGE, SPONGIA OFFICINALIS.

Isfeng, ARAB.
Eponge FR.
Schwamm, GER.
Mooabadul, GUZ. HIND.
Spungia, IT.
Uniwatta, JAP.
Abermoordeh, PERS.
Esponja, SP.

A soft, light, very porous, compressible substance, readily imbibing water, and as readily giving it out again; and now ascertained to be

a species of zoophite. The colour is generally yellow or brown.—*Faulkner.* The Officinal Sponge is so well known for its economic uses, that it does not require a detailed description. Numerous species are known, with soft porous bodies, traversed by tortuous canals; but the officinal Sponge is imported from the Mediterranean and Red Sea; some of the coarser kind from the West Indies. Those of the British Seas would probably answer equally well for burning. When collected, Sponge contains numerous small fragments of corals and minute shells, from these it must be freed before it can be used. Sponge is composed of Gelatine and Coagulated Albumen. (*Hatchett.*) When burnt, its ashes give Carbon, and some Silex, Carbonate and Phosphate of Lime, Carbonate of Soda, Chloride and Iodide of Sodium, Bromide of Magnesia, with a little Oxide of Iron.—*Royle.*

(7834) SPRAT. BRISTLE-FINNED SPRAT. SETIPINNA. A small fish of the herring tribe found in Burmah seas. It is, however, easily distinguished by a long filament or bristle, which is attached to each pectoral fin. This and another species are often called sprats by Europeans, and they belong to the same tribe.—*Mason.*

(7835) SPRINGS. The Tenasserim Provinces are well supplied with hot springs; and some of them are probably not inferior in their medicinal qualities to the fashionable Spas of Europe and America. Though their waters have never been subject to any minute analysis, yet we know there is a great variety in the properties of different springs. They may be arranged in three different classes,—carbonated, sulphureous, and saline.

Carbonated thermal springs.—The hot springs on the Ataran, according to Dr. Helfer's description, belong to the carbonated class. They are situated within two miles of the old town of Ataran, and Dr. Helfer writes: "There are ten hot springs or rather hot water ponds, of which I could only examine the nearest, as the access to the others was through deep water at 130° Fahrenheit This one was a semicircular pond about fifty feet in circumference. In one place it was thirty-five feet deep. The quantity of carbonic acid which the springs evolve, seems to render the neighborhood peculiarly adapted to support vegetable life. —The ground around the spring is strongly impregnated with iron, and the water which runs over the ochre mud has a strong styptic taste. The springs on the Ataran approach in their composition nearest to the celebrated waters of Tœplitz. "Their medical properties would render them excellent remedies in a number of diseases: liver complaints would find a powerful remedy in them. If Amherst should be selected as a resort for invalids, the hot springs on the Ataran could easily be turned to advantage. In a direct line, they would be only four or five hours distant, and a road could be cut through the country without difficulty, so that patients could be removed there and bathe in loco." Dr. Morton found, on analysis, that the waters contain a considerable quantity of calcareous matter, and that the tufa, which it deposits on the border of the springs, is a carbonate of lime. They appear to arise from the mountain limestone, and thus to hold a geological position similar to that of the hot springs of Great Britain, most of which rise from strata below the coal, and hence from, or through the limestone.

Sulphureous thermal springs.—About four miles below Matah at the forks of the Tenasserim, and a few miles north of the latitude of Tavoy, there are hot springs highly charged with sulphuretted hydrogen gas, so readily recognized by its smell which is precisely that of the washings of a gun barrel; the odor in both instances being produced by this same gas All the stones in the springs are of a bright brass color, produced apparently by the deposition of the sulphur; and although the virtues of these waters are hidden from man, they appear to be well known to the beasts of the forest. To judge from the tracks around in the morning, the most incongruous parties are held here every night. The delicate little tread of the chevrotain and barking deer, are seen side by side with the massive steps of the elephant and rhinoceros; and the tiger, and the leopard seem to lay aside their fierceness, and peaceably walk away satisfied with a draught of the much coveted beverage. Dr. Helfer said these springs belonged to "the class of sulphureous mineral waters, tinged slightly with chalybeate, like the water of Brighton." Their heat above the atmosphere is not great. Mr. Bennett at a recent visit, found the thermometer to rise in the hottest spring to only 119°. They rise from the slate rocks, like the warm springs of a considerable part of Germany.

Saline Thermal Springs.—On the margin of the granite range east of Tavoy, either near the junction of the slate and granite, or in the granite itself, is a series of the hottest springs in the Provinces. I have visited, says Mr. Mason, four or five in a line of fifty or sixty miles, and found them uniformly of a saline character Around one nearly east of Tavoy, the stones are covered with an efflorescence resembling epsom or glauber salt. Mr. Bennett found the Thermometer in this spring, to rise to 144°. Major McLeod visited one of the series at Palouk, and writes: "There are two spots where the springs show themselves. One immediately in the right bank of the river, and another two or three minutes walk to the northest inland.—There must be 30 or 40 bubbling up along a line of about 50 feet by 20.—The hottest was 196°

another 194°. No disagreeable smell or taste." The hottest springs are at Pai, ten or fifteen miles north of those visited by Major McLeod, and according to Phillips they are hotter than any on record out of volcanic regions, with the questionable exception of three springs in China, which, " probably exceeded the temperature of the air from 70 to 120 degrees." The principal spring at Pai,—for there are several,—is in a little sandy basin in the midst of granite rocks on the margin of a cold-water stream, where it bubbles up from three or four vents, and on immersing the thermometer into one, the mercury rises to 189°, within fourteen degrees of boiling water. Its location is rather peculiar, not being in a valley like the others I have seen, but on the side of a hill more than a thousand feet above the level of the sea, and surrounded by large masses of coarse grained granite rocks, which seem to have been detached from the summit above.—*Mason.* See MINERAL SPRINGS also HOT SPRINGS.

(7836) SQUALIDÆ, a family of Fishes of the section *Chondropterygii*. In this family, which includes the various species of Sharks, the branchiæ are attached by their outer margin to the skin, and the water taken in for respiration makes its escape through narrow outlets corresponding in number to that of the interspaces between the branchiæ: the number of these openings is usually five. So far the present fishes agree with the Ray or Skate family [RAIIDÆ]; but the peculiar rhomboidal form of the body renders it easy to distinguish the Rays, which moreover have a peculiar cartilage arising from the nasal part of the skull, and extending towards and even meeting the anterior part of the crest of the pectoral. This character is pointed out by Muller and Henle, who state that it is found in all the Ray tribe, and also in *Rhinobatus* and *Pristis*, whereas there is no trace of it in any Shark.

In the Sharks the body is elongated, and tapering gradually from the head to the tail, or but little dilated in the middle. The muzzle is rounded or pointed, depressed, and projects over the mouth; the nostrils are situated on the under side of the muzzle, in the form of oblique openings, which vary somewhat in figure, according to the species. The fins generally consist of two dorsals, two large pectorals, two ventrals, an anal fin, and a caudal, the form of which is peculiar. The portion of the tail of the Shark which supports the tail fin is almost always bent upwards at an obtuse angle with the body; the fin itself may be divided into three parts—a superior, an apical, and an inferior portion; that which runs along the upper surface is usually narrow; that on the under surface is broader, but decreases in width to its point of junction with the apical portion, which is more or less dilated at the extremity and obliquely truncated. Such is the most common character of the tail and tail-fin in the present fishes, and one which is not found in any recent fishes not belonging to the Chondropterygian group. The Male Sharks are smaller, and differ externally from the Females in possessing two elongated appendages, one of which is attached to the hinder edge of each of the ventral fins, the uses of which are not known. Some species of sharks bring forth their young alive, whilst others are inclosed in oblong simitransparent horny cases, at each extremity of which are two long tendrils. These cases are frequently found on the sea-shore, and are called Sea-Purses, Mermaid's Purses, &c. They are deposited, observes Mr. Yarrell, by the parent shark near the shore in the winter months. The convoluted tendrils, hanging to sea-weed or other fixed bodies, prevent the cases being washed away into deep water. Two elongated fissures, one at each end, allow the admission of sea-water; and the young fish ultimately escapes by an opening at the end, near which the head is situated. For a short time the young shark continues to be nourished by the vitelline fluid contained in the capsule attached to its body by the connecting pedicle, till having acquired the power of taking food by the mouth, the remains of the ovum are taken up within the abdomen, as in birds and some other animals. " A curious peculiarity has been observed in the young both of the Sharks and Skates during a very early stage of their existence. From each of the branchial apertures branchial filaments project externally; each filament contains a single minute reflected vessel, in which the blood is thus submitted to the action of the surrounding medium. The appendages are only temporary, and the blood of the fish is afterwards aerated by the true gills. This very interesting discovery, which, I believe, is of recent date, forcibly reminding us of the temporal external branchiæ in the young Batrachian Reptiles in the tadpole state, has been observed by Mr. Richard Owen in the Blue Shark (*Carcharias glaucus*); by Mr. John Davy, in the Torpedo; and by Dr. Allen Thompson, of Edinburgh, in the Thornback. Cuvier had previously noticed it, and, in 'Regne Animal,' has referred to a figure, published by Schneider, of a very young shark in this condition, for which, regarding it as the normal state of the fish, that industrious pupil of Bloch had proposed the name of *Squalus ciliaris*."—(Yarrell.)

The *Squalidæ* and *Raiidæ* have long occupied the attention of Professor Muller and Dr. Henle, who have conjointly published an excellent work on these groups, 'Systematische Beschreibung der Plagiostomen.' The characters of the various genera into which they divide the Sharks are here given.

(7837) *Scyllium*, Cuv.—This genus is res-

ricted to such species as have the anal fin placed nearer to the head than the second dorsal fin.

(7838) *Pristiurus*, Bonah., differs from *Scyllium* in having a long snout, and also in possessing a series of larger scales, arranged like the teeth of a saw on the upper edge of the tail. It contains but one species.—*Eng. Cyc.*

(7839) *Chiloscyllium*.

(7840) *Hemiscyllium*, Muller and Henle.

(7841) *Crossorhinus*, Muller and Henle.

(7842) *Ginglymostoma*, Muller and Henle.

(7843) *Stegostoma*. Muller and Henle.

(7844) *Carcharias*, Cuv.—Teeth flat, sharp, and serrated on each side, either in the upper jaw only, or in both jaws.—*Eng. Cyc.*

(7845) SQUILL, COUNTRY. ERYTHRONIUM INDICUM. Rottl.

Unsool, Iskeel, ARAB.	Peyaz-i-dushtie, PERS.
Nurriala, CYNG.	Nurri-Vunjyum, TAM.
Junglee-Peeaz, DUK. GUZ. HIND.	Addi Vitella guddaloo, TEL.
Nurri Vungayum, TAM.	Unsool, ARAB.
Junglie piaz, DUK.	Kanda, HIND. and TEL.

This is not the produce of the Scilla maritima, though it has, improperly, been so called by the English in India, from its resemblance to the true Squill in medicinal virtues. Ainslie did not find the Native medical Practitioners employ it. Farriers are in the habit of using it, in conjunction with other articles, for horses, in cases of Strangury and Fever. It grows in abundance in these districts, in waste, sandy soils.—*Ains. Mat. Med. p.* 44.

(7846) SQUILL, SEA ONION.

Meerzwiebel, GER.	Scille, FR.
Scilla, Cipolla marina, IT.	Scilla, LAT.
	Cebola albarrana, SP.

A perennial bulbous rooted plant (*Scilla maritima*), found on the shores of Spain, Portugal, North of Africa, and the Levant. The bulbs are pear-shaped, and vary in size from that of the fist, to the compass of a child's head. The root is very nauseous, intensely bitter, acrimonious, and causing inflammation when rubbed in the skin. As met with in the shops, squill is commonly in the form of the dried shreds of the root. It is one of the most useful remedies in the materia medica.—*Faulkner.*

(7847) STACHYS. LABIATÆ. These are plants of no great beauty, and being of a weedy nature are hardly worth cultivating.—*Riddell.*

(7848) STACHYTARPHETA MUTABILIS. VERBENACEÆ. A shrubby plant with variegated scarlet flowers in terminal spikes; propagated by cuttings.—*Riddell.*

(7849) STACHYTARPHETA JAMAICENSIS. An annual, with blue flowers in terminal spikes; common.—*Riddell.*

(7850) STAGMARIA, a genus of Plants belonging to the natural order *Terebinthaceæ*. It was named by Mr. W. Jack, assistant-surgeon in the East India Company's service, and author of 'Malayan Miscellanies,' from the Greek word στάγμα, 'a dropping fluid.' The tree *S. verniciflua*, which is the *Arbor vernicis* of Rumphius, and the Kayo Rangas of the Malays, is full of acrid resinous juice, and is a native of the Eastern Islands, but not very abundant in Sumatra, though occasionally found in the neighbourhood of rivers. The calyx is tubular, with the limb irregularly ruptured, deciduous. Petals 5, longer than the calyx, obtuse spreading, subreflexed. Stamens 5 alternating with, but inserted above, the petals into the stipelike torus. Filaments filiform, equal to the petals in length. Anthers oblong. Ovary stipitate, 3-lobed, lobes 1-seeded, 1-2 of which are usually abortive. Styles 1-3, terminating the lobes of the ovary. Stigmas obtuse. Berry kidney-shaped, furrowed, 1-seeded, with a warty rind. Embryo exalbuminous, erect: cotyledons united; radicle incurved. The genus is nearly allied to *Rhus*, but besides the difference indicated in the above character, it has simple leaves, which are without stipules. The wood of the tree is of a fine dark colour towards the centre. The bark exudes a resin which is extremely acrid, causing excoriation and blisters when applied to the skin, in this, as well as in becoming black when exposed to the air, it resembles the *Melanorrhœa*, Cashew-Nut Tree, Poison-Oak, and many others of the *Terebinthaceæ*. According to Rumphius, this tree yields the celebrated Japan lacquer, or varnish, and he considers it the same with that of Siam and Tonquin. Loureiro however represents the latter to be the produce of an *Augeia*. Mr. Jack says the varnish of Siam and Cochin-China is probably the best, but that of Celebes and of Java, which is the produce of this tree, is also employed for the same purposes, and cannot be much inferior, as it bears an equally high price. Rumphius says the exhalations of this tree are considered noxious, and the people of Macassar, and of other parts of Celebes in particular, entertain such dread of it, that they dare not remain long under it, much less repose under its shade. As however it furnishes the celebrated varnish, the Chinese and Tonkinese boldly repair to the tree, but employ caution in collecting the resin. This they do by inserting into the trunks two pieces of bamboo, sharpened at their points, in such a manner as to penetrate the bark in a somewhat oblique direction. These remain all night, and are extracted before sunrise the next morning, the trees yielding no juice during the day. This fluid resin bears a high price, being sold in Tonkin and Camboja for 33, 50, or 60 dollars, the pecul, of about 133 lbs, but in many of the provinces of China for 200 or 300 dollars. The varnish is prepared for use by boiling it with an equal weight of the oil of Tang-yhu, which is a Chinese tree allied to the *Mimusops elengi*, from whose fruit an oil is

prepared. The proportions are varied according to the purposes for which the varnish is required. Sometimes dry pigments are added for the sake of red or other colours. The Japanese are the most skilful in preparing and ornamenting all kinds of work with this varnish, and their black lacquered works are conveyed to all parts of the world. (Jack, *Malayan Miscellany*, No. 3 reprinted by Sir W. Hooker.—*Eng. Cyc.*

(7851) STAGMARIA VERNICIFLUA, one of the black varnish trees of China.—*O'Sh.*

(7852) STALACTITE AND STALAGMITE. Stalactitic Carbonate of Lime occurs chiefly in long masses suspended from the roofs of caverns in limestone rocks. Stalactites appear to be continually forming; water containing carbonate of lime held in solution by carbonic acid, trickling through crevices in the roofs of the caverns, gradually during its exposure to the air loses its carbonic acid, and consequently deposits its carbonate of lime; the water passing over the portion first deposited gradually adds to it, and eventually gives the carbonate of lime its great length and stalactitic character. The flatter deposits, called stalagmites, are formed on the floor of the cavern by the water there depositing that portion of its carbonate of lime which is not separated during the formation of the stalactite. Stalactic Carbonate of Lime is met with in the veins of lead-ore in Durham and Northumberland. Caverns are sometimes nearly filled with these deposits, which in some cases are of very large dimensions. The most remarkable instances of their occurrence in Britain are in the cavern at Castleton in Derbyshire, and Macallaster Cave in the Isle of Skye. The grotto of Antiparos in the Archipelago, the Woodman's Cave in the Harz in Germany, and that of Auæelle in France, are striking instances of their formation in other countries. Besides the occurrence of this variety of carbonate of lime in the stalactitic form, it is sometimes met with reniform and tabular, and in other imitative shapes. The facture is sometimes perfectly lamellar, occasionally fibrous, the fibres diverging from a centre, with pearly or silky lustre, and sometimes resinous or waxy. The colour varies from white to grayish, brown, red, and yellowish-white. Opaque, but frequently translucent. The Oriental Alabaster, much employed by the ancients in statuary and the formation of vases, appears to be of stalactitic origin.—*Eng. Cyc. Carbonate of Lime*, is a very abundant mineral in the Tenasserim Provinces and embraces several varieties. Stalactical Carbonate of Lime is one of these. All the Tenasserim limestone caves have stalactites hanging from their roofs; and stalagmites raised on their floors. The Siamese Karens often bring over bits of limestone of the shape of a shell, and when broken, a shell usually of the genus melania appears, that has been encrusted with carbonate of lime. Much of the alabaster of which ornaments are made is stalagmite; but all the alabaster images of the Tenasserim coast are made of marble: and not of compact gypsum, which they much resemble.—*Mason.*

(7853) STALAGMITES (from σταλαγμός, a dropping), the name of a genus of Plants belonging to the natural order *Clusiaceæ*, or *Guttiferæ*. It has polygamous or bisexual flowers; 4-5 sepals, which are persistent and bractless; 5 petals alternating with the sepals; 4-5 united stamens, the bundles flat, elongated, and divided at the apex into several short antheriferous portions opposite to the petals, and alternating with 5 large truncated glands; the anthers are 2-celled, bursting longitudinally; the ovary is 3-5-celled, with 1 ovule in each cell; stigma 3-5-lobed; the fruit a berry. The species are trees natives of the East Indies and Ceylon, and belong to the family which produces the gamboge of commerce. Dr. White states that one of the species, the *S. ovifolia*, which is a native of Ceylon, yields a true gamboge, which is employed in commerce. It is known by its oval shining leaves, its lateral fascicled flowers, male and hermaphrodite mixed. Its anthers are arranged in 6 or 8 bundles, and it possesses a 3-celled 1-3-seeded ovary.—*Eng. Cyc.*

(7854) STALAGMITES OVALIFOLIA, BROWN AND GRAHAM. *Syn.* Xanthochymus ovalifolius. (Roxb. ii. p. 632.) A native of the Southern provinces of India and Ceylon. The seeds were sent from Ceylon by General Hay MacDowal, to the Calcutta Garden, under the Cingalese name *Ambul Ghorka*; in 7 to 10 years the trees began to blossom during the whole of the hot season, and in July 1812, when ten years old, they produced perfectly ripe fruit. Dr. Wight is of opinion that this tree yields one kind of gamboge in Ceylon. It is desirable to ascertain what may be the produce of the trees in the Calcutta Garden.—*O'Shaughnessy, page* 236.

(7855) STALAGMITES PICTORIA, *Syn.* XANTHOCHYMUUS PICTORIUS. (Roxb. ii. p. 633.)

Dampel, BENG. and HIND. | Kata Ghorka, CING.

A native of the mountainous districts of India; leaves opposite, linear, lanceolate; flowers in lateral fascicles, berry ovate, pointed. Fruit ripens in November and December, and the tree yields a large quantity of inferior gamboge.—*O'Shaughnessy, page* 236.

(7856) STAPELIA, ASCLEPIADEÆ.—This is an extensive genus of plants with curiously marked flowers like a toad's back, they are star-shaped, and grow from the roots; these plants being succulent, are apt to drop off if grown in too rich or moist a soil, they give seed and may be cultivated from it, but more readily from slips shaded partially, and watered sparingly.—*Riddell.*

(7857) STAPELIA BUFFONIA. ASCLEPIADEÆ.

Kar alum. DUK.

The Toad-like Stapelia.

(7858) STAPELIA GRANDIFLORA AND S. VARIEGATA.—The species are stemless plants with fœtid flowers, star-shaped, colour resembling a toad's back: the plants should not have much water or be exposed to the sun; easily propagated by seed or cuttings.—*Riddell.*

(7859) STAPELIA VIRGATA. ROTTL.

Callymolian, TAM | Koondana Komooloo TEL

Ainslie's Mat. Med. p. 259.

(7860) STAPHYLEA (from σταφυλή, a bunch of grapes), the name of a genus of Plants, the type of the natural order *Staphyleaceæ*. It has a coloured 5-parted calyx, with an urceolate disc at the base; five upright petals; five stamens standing round the disc; an ovary with from two to three styles, with a small stigma; a membranaceous swelled capsule with two or three cells, and one or two seeds in each. This genus has six species, of which one is a native of Europe, one of North America, one of Japan, two of Jamaica, one of Peru, and one of the Himalayas.—*Eng. Cyc.*

(7861) STAPHYLEA EMODI is an Indian species: it was found by Dr. Royle in the Himalayas, at an elevation of 7000 feet. (Royle, 'Ill. Him. Bot.,' p. 165.)

(7862) STAPHYLEACEÆ, *Bladder-Nuts*, a small natural order of Plants belonging to the Syncarpous group of Polypetalous Exogens. They are shrubs with opposite pinnate leaves, having, both common and partial petioles, and the flowers arranged in terminal stalked racemes. The calyx has five sepals, which are imbricated in æstivation; petals five; stamens five, alternate with the petals, perigynous; ovary 2- or 3-celled, seated on a disc; fruit membranous or fleshy, frequently deformed by the abortion of some of its parts; exalbuminous roundish ascending seeds, with a bony testa, large hilum, and thick cotyledons. There are only three genera and ten species belonging to this order, which are inhabitants of the warmer and temperate parts of the earth. Only one species, the *Staphylea pinnata*, is found in Europe. This order was separated by Lindley from the order *Celastraceæ*, with which it is most nearly allied, but from which it is distinguished by its opposite pinnated stipulate leaves. One of the genera, Turpinia has unisexual flowers. The species do not possess active properties. The seeds of all contain a mild oil, which may be expressed.—*English Cyclopedia, page* 892.

(7863) STARCH.

Abgoon, ARAB.	Neeshashta, PERS.
Amidon, FR.	Kruchmal, RUS.
Amidam, GER.	Amidon, Almidon, SP.
Amodi, IT.	

Procured generally from wheat flour and potatoes. The best kind is white, soft, friable, and easily reduced to powder. It is insoluble in cold water and alcohol, but readily affords a gelatinous solution in warm water, which is largely employed for stiffening articles of wearing apparel, and for dressing some descriptions of goods after weaving. It is also much employed by calico printers, and others.—*Faulkner.*

Starch is a substance which is found very generally present in the vegetable kingdom. It occurs in the forms of irregularly shaped granules inclosed in the cells of plants. It is easily detected in the cells of plants under the microscope, by the addition of a small quantity of solution of iodine which immediately gives to the starch granules a blue colour. Starch can be readily separated from the tissues of plants, on a large scale by bruising them and stirring them in water; when left at rest the cellulose of the tissue falls to the bottom of the vessel, and the starch floats in the water. If the water containing the starch is now poured off and allowed to stand a few hours the starch will fall to the bottom of the vessel, and is easily collected. In this way it is obtained for commercial and dietetical purposes. Starch is thus found to be diffusible through water, but not soluble in it. It differs then from cellulose, on the one hand, by its diffusibility through water; and on the other, from dextrine, sugar, and gum, by its insolubility. In composition it resembles these substances, and during the growth of the plant it is evidently converted into one or the other according to the necessities of the plant. It contains carbon, hydrogen, and oxygen (C_{12}, H_8, O_3,) and belongs to that series of substances to which the term Dextrine has been applied. In certain groups of plants, intermediate substances between those mentioned have been obtained. Thus, in the Lichens, a substance exists which resembles starch in many of its properties, but does not assume its definite granular form. This is called Lichein. Another substance also closely approaching starch in its general characters is Inulin. This substance is not coloured blue by iodine, and has other distinctive properties. It is rounded in the various species of *Inula*, and has also been detected in other plants. From these facts we may gather that Starch is the result of the chemical activity of the plant-cell at particular stages of its growth. It is one of those secretions to which the name assimilable is applied, and is evidently capable of undergoing great changes during the life of the plant. It is almost constantly present during the earlier stages of cell-growth, so much so as to lead to the supposition that its presence is universal during certain stages of the life of the plant-cell. In some plants and parts of plants however it rapidly disappears, being either converted into sugar or cellulose, or some of the

numerous unassimilable secretions of plants. That the latter takes place very frequently is rendered probable by the discovery that caoutchouc and gutta percha can be artificially manufactured from starch, whilst it has long been well known that starch may be converted into sugar and gum. Starch differs from sugar in its not being fermentable. It is however readily convertible into sugar by agents which induce fermentation. It has been supposed that the protein of the plant-cell acts chemically in converting starch into sugar during germination, and the term Diastase has been applied to the proteinaceous matters found in connection with the starch of germinating seeds. Starch occurs usually in the cells of plants in the form of granules. In the earlier stages of their growth these are attached to the sides of the cell, or to portions of the endoplastic protein wherever they may be placed. In most cases these granules are simple or single; but when they are developed near each other a union is formed of one or more, and the result is a compound granule. Schleiden also describes Amorphous Starch, and states that in some plants the sides of the cells are lined with a layer of starch having no definitely-formed granules. In the majority of starch-granules a little spot may be seen which is called the hilum, and has been by some regarded as a nucleus or central point of the formation of the granule. It does not however seem to bear the relation in all cases. Much difference of opinion exists as to the true nature of the starch granule. Some observers have supposed that it consists of a series of flattened plates or dishes laid one upon the other, the result of successive depositions of starch matter. This view will be seen to be erroneous if the starch-granule is submitted to heat, or sulphuric acid, when it will be found to unfold and exhibit itself in the form of a vesicle or bag. From this it appears that this bag is compressed in the ordinary state of the starch, and its sides being folded in, gives it the appearance of dishes. At one time it was supposed that starch was characteristic of the vegetable kingdom. Veichow has however demonstrated its existence in connection with cellulose in a large number of animals. Bush first pointed it out in the human brain. It has been found also in the human blood; and with cellulose and sugar it can no longer be regarded as truly characteristic of the vegetable kingdom.

Starch is a substance easily manufactured, and is largely used in several of the arts, as well as an article of diet. It can be obtained from a great variety of plants, and many of the most productive of it are natives of the tropical countries in the East. Starch occurs in the forms of irregularly shaped granules enclosed in the cells of plants, and can be easily separated from the tissues of plants, on a large scale by bruising them, and stirring them in water; when left at rest the cellulose of the tissue falls to the bottom of the vessel, and the starch floats in the water. During certain stages of the life of the plant-cell, the presence of starch is supposed to be universal, but in some plants or parts of plants it rapidly disappears, being either converted into sugar or cellulose, or some other secretion. Indeed no two writers agree as to the per centage of starch yielded by different plants, nor is this result unexpected, for even in the same plants, the quantity of starch varies with the season, the soil, climate, age, ripeness, length of time the roots have been out of the ground, &c. It will be seen however that starch is one of the constituent parts in all mealy farinaceous seeds, fruits, roots, and other parts of plants. In the West Indies, the Maranta arundinacea, allomyca, and nobilis and various species of Canna furnish this fecula, Two varieties of Cassava furnish a very superior quality, which is known in commerce as Brazilian arrow root, the amylaceous matter from Zamia pumila and other species at the Cape of Good Hope has been sent as arrow root, a similar product is obtained in Chili, from Alstromeria pallida and the Singalese get a kind of starch from the nut of the Cycas circinalis by pounding, the fresh kernels. The following are the chief fecula or starch-like substances of the East and may be consulted separately also under the head ARROW-ROOT, FOOD AND MARANTEA.

Arrow root, West Indian,	... Maranta arundinacea.
Arrow Root, East Indian	... Maranta ramossissima. ... Curcuma angustifolia.
Do. do.	... from other species of Curcuma.
Do. do.

Telinga potato,	... Amorphophallus campanulatus,
Sweet potato,	... Batatas esculenta.
Ceylon moss,	... Plocaria candida.
"Kotee kalangoo."	... Aponogeton Monostachyon.
Farina of	... Parkia Biglobosa.
Chara kelangoo,	... Plectranthus tuberosus.
Champoo,	... Caladium Nymphifolium.
Sago, Indian,	... Cycas revoluta.
,,	... Cycas Circinalis.

The specific quantity of starch derived from several plants varies from 1·41 to 1·47. and probably those specimens prepared from dry seeds, such as wheat and maize starch, which, as commercial articles at least, are less pure than those prepared from recently dug roots, have also the lowest density. As an article of diet, the most tenacious varieties of starches are preferred, on account of the economy of employing an article of which a less quantity will suffice, and the same is true when applied to starching linen, provided the Jelly be not deficient in clearness. In respect to tenacity, there is a very great differ-

ence between the Jellies prepared from the different starches, a disc of jelly prepared from sweet Cassava breaking with 78 grains, while that of a jelly from the *Tous les mois*, of the West Indies did not break with a weight of 2,446 grains. Experiments of a similar kind are required to test the starches of India. When Starch jelly is used for the purpose of starching or glazing linen, or cotton goods, the most transparent varieties are preferred, provided they also possess the requisite tenacity, but on this point, also experiments regarding our Indian Starches are necessary.—*Madras Exhibition of* 1857. *English Cyclopædia. Simmonds' Commercial Products.* Starches from different plants are best distinguished from one another by examining either as transparent opaque objects their grains or globules with a microscope, for though in the same species, there are considerable differences in size and form, the different kinds are on the whole quite distinguishable. This is of the more importance because the adulteration of starches is chiefly effected by mixing a cheap variety with a higher priced one, and in practice when the observer has a number of pure and authentic specimens before him to have recourse to as standards of comparison the discrimination is by no means difficult.—*Hassall.*

(7864) STATICE. PLUMBAGINEÆ. Sea lavender.—Many of these species bear pretty purple, white and blue flower, and are much cultivated in Britain; the S. Arborea is a very handsome shrub and requires a large space for its spreading roots, is propagated by seed, in good garden soil.—*Riddell.*

(7865) STAUNTONIA, a genus of Plants belonging to the natural order *Menispermaceæ* and tribe *Lardizabaleæ*, named after Sir George Staunton. This genus is remarkable as being one of those which is common to China and the Himalayan Mountains, and has hence afforded useful inferences respecting the districts where the tea-plant might be successfully cultivated. The genus is characterised by having monœcious flowers; the male having a 6-leaved calyx, with the leaflets in two rows; petals 6 or wanting; stamens 6, opposite to the petals, distinct or monadelphous; anthers adnate, opening outwards; rudiment of ovary. The female flower has the calyx of the male; no petals; 6 sterile dwarfish stamens; ovaries 3, distinct, oblong, with many ovules; stigmas sessile, simple-flowered. Berries often fewer than 3, divaricate, fleshy, opening longitudinally on their inner side. Seeds numerous, oblong-ovate, or reniform; embryo minute in base of a fleshy albumen; radicle inferior. The species are divided into two subgenera—*Stauntonia* being without petals and having monadelphous stamens: *Holbaellia* having 6 gland-like petals and the stamens free. The species form large climbing shrubs, with alternate petiolate peltately digitate leaves. Leaflets leathery in texture, 3-nerved, very entire, with all the petioles swelled and jointed at both extremities; racemes fascicled, axillary, a few flowered at the base of the branches. Flowers white, externally purple, fragrant. Berries large and purple. The Himalayan species are found in Nepal and in 30° N. lat., at elevations of 5000 and 6000 feet. Their fruit, having a sweetish pulp, is eaten by the natives of these mountains, and they might no doubt be acclimated in the gardens of this country, as they experience a considerable degree of cold at the elevations where they are found.—*Eng. Cyc.*

(7866) STEARIN. The harder portion of animal fats; *olein* or *elain* being the softer one. Stearin yields an acid, called *Stearic acid*, having the form of brilliant, white, scaly, crystals, which is largely employed in soap and candle making. (*Waterston.*)—*Faulkner*

(7867) STEATITE, a soft magnesian mineral *silicate of magnesia*—unctuous to the touch, for which reason it is also termed *soapstone*. It is also known in Commerce as *French chalk*. Its sp. gr. is 2.65 to 2.9; its colour is usually greyish, but, when worked and varnished, it becomes dark olive green. It occurs in beds generally associated with talcose slate. Like *potstone* and *serpentine*, which it nearly resembles in composition, it becomes considerably harder by exposure to the air. When first raised it may be easily turned with chisels: the turned articles may be polished first with sand and water, and afterwards with tripoli and water, and, for the highest gloss, with rotten stone and oil, woollen cloths being used in each case. When the steatite has become hard, the methods employed for alabaster, may be resorted to. Steatite has also been named *figure stone* in consequence of its having been used as the material for idols and other figures, which form the household gods of the Chinese: it was formerly supposed that they were made of a preparation of rice. The refractory nature of soapstone, and the facility with which it is worked, admit of its being cut into slabs for fire stones in furnaces and stoves, and for jambs for fire-places. It is also mixed with blacklead in the manufacture of crucibles. It is bored out for conveying water instead of lead pipes. It is an excellent material for kitchen-sinks, wash-tubs, bath-tubs, urinals, &c. It is readily wrought, and may be bored, turned, and planed by the ordinary tools of the carpenter, and it may be screwed together almost as easily as hard wood. It is used in the manufacture of porcelain: it makes the biscuit semi-transparent, but brittle. It forms a polishing material for serpentine, alabaster, and glass, and removes grease spots from cloth. It is ground into a powder and used for diminishing the friction of machinery. Dana states that soapstone is used in the United States for the sizing-rollers in cotton factories; in which case they

are of large dimensions, such as 4½ feet long, and 5 to 6 inches in diameter. The advantage of soapstone as a material for baths and sizing rollers, are, that it is not affected by the acid usually employed in sizing, and is not liable to warp, contract, or expand, by change of temperature and moisture.—*Tomlinson.* *Steatites* are common in Southern Asia, and of all sorts and colors. At Kurnool and at Salem and near Mysore there are very fine and beautifully white soapstones, and near Chittoor there is a valuable description, (similar to the Cornish serpentine) procurable in large blocks and suitable for many statuary and decorative purposes. There is a quarry of excellent potstone at the Nagery Hills, which is likely to become a valuable addition to the Madras trade. The stone is of fine grain, easily worked with the chisel and susceptible of a high polish, when oiled, this stone resembles in a great degree black marble. Some interesting specimens of manufacture in this material, show a considerable advancement in design and execution.—*M. E. J. R.* See SOAPSTONE.

(7868) STEEL.

Acier, Fr.	Chalybs, Lat.
Stahl, Ger.	Stal, Rus.
Foulad, Guz. Hind. Pers.	Acero, Sp.
Acciajo, It.	Stal. Sw.

Is iron combined with a small quantity of carbon. It is brittle, resists the file, cuts glass, affords sparks when struck on flint, and retains the magnetic virtue for any length of time. It loses this hardness by being ignited, and cooled very slowly. Steel is used for making razors, surgeon's instruments, swords, forks, &c.—*Faulkner.*

Conasamoondrum Steel, is made at several villages in the Circar of Elgundel at Ibrahimputnum, and Konapore in the Karaolla Purgunnah, and at Atmacore and Chintulpet in the Velloorla Talooka, it formerly was prepared at several other places, but the Steel furnaces in them are now abandoned. The teepoor as it is called, the raw material of the steel, is manufactured at Maytpilly a village twelve miles south of the Godavery, belonging to Balmookund, from a ferruginous sand procured from gneiss by roasting, pounding and washing. The whole process of the manufacture of this steel is detailed with accuracy and minuteness by Dr. Voysey in the first volume of the Asiatic Society's Transactions and also by Dr. Malcolmson in the Geological Society's Transactions of 1839. Both these gentlemem visited the steel furnaces at Konasamoondrum in the adjoining district of Neermul which supply the material from which the Damascus blades are manufactured. The steel manufactured at these villages is very inferior to the Konasamoondrum steel—and does not fetch half its price. Yet the teepoor is used for both, and the same care is apparently bestowed in the preparation, the only difference that could be detected was that the pure iron which along with the teepoor and the bran is placed in the crucible, is in the case of the Konasamoondrum steel prepared from the yellow clay iron ore, found in the laterite at Taatpilly, while at Ibrahimputnum and the other villages any iron without reference to the ore from which it is smelted is used. The exact chemical condition of the metal under the form of steel has as yet evaded scientific investigation which renders it probable that the inferiority of the Ibrahimputnum steel may be attributable to this one neglect. The Mogul who rents the Konasamoondrum furnaces would seem to be of this opinion as he holds a strict monopoly over the Taatpilly iron, insomuch that I had some difficulty in procuring a specimen of the metal. In the steel furnaces, five men are employed, viz; the principal workman who has the care of the crucibles, which he is continually moving about the furnaces by means of a long iron rake, and four bellows men. The daily pay of the chief is two seers of rice, and two annas a day. The others receive half the rice and money, if the steel comes out of the crucible at all blistered or unequal on the surface, it is rejected as worthless.—There are two kinds of crucibles, the large and the small, each of which contains a lump of steel of from one to two pounds in weight. The cost of the furnace varies from four to six annas for the smaller pieces, and from eight to ten annas for the larger. The workmen complain that the Hyderabad market is now lost to them, their steel being undersold by steel from Europe, which is there preferred for the manufacture of arms. The chief consumption is confined to the country about, where it is used for hatchets, sickles, &c. At Lingampilly and another village, both close to Aimulwarrah, barrels for Pistols and Matchlocks are prepared. All kinds of old iron, old moat buckets, agricultural instruments, &c. are collected and formed into rods of the thickness of a man's finger.—These are then twisted by an instrument for the purpose; three or four of these rods are joined together lengthways, another band of iron of the same breadth and of the thickness of a third of an inch is taken and welded to this, both being formed into a band which is twisted and afterwards beaten into a solid cylinder which is bored by a hard steel chisel. Pistol barrels are made after the same manner, but less trouble is bestowed in the manufacture of a coarser kind of Matchlocks—the process commencing with simply twisting a band of metal. Pistol barrels manufactured by the first process are sold for Rupees twenty and upwards, and Matchlock barrels so prepared for double that amount, the last made after the simpler manner are much cheaper. Swords, daggers, bullum

and spear heads are manufactured at Elgundel from the country steel.—Cuth. Davidson, Assistant Resident.—*M.G.C. for Ex. of* 1851. The manufacture of steel is a branch of Industry for which India has long been celebrated. This substance can be made of good quality in small quantities and at a comparatively trifling cost; the process is more carefully conducted than that of making iron and the results are on the whole more satisfactory. Some defects however are found in the cast steel of India, which interfere materially with its sale in the European market. These are the hardness of the external surface of the melted lumps, and their inequality, few being alike. The hardness is caused by the lumps cooling too rapidly on the surface from the small size and thinness of the crucibles. This branch of manufacture is susceptible of improvement in India, and there is a great abundance of rich ores, fluxes, and refractory clay in most of the districts of this Presidency. The great desideratum, however, is a bed of good coal that would convert into coke Some of the black sandstones and band irons exhibited in this class with their accompanying strata of lime, fire-clay, white pipe-clay and thick beds of yellow and red sandstone, are very similar to those found in the coal bearing strata of Bengal and other countries.

The steel wire of Chinnapatam in Mysore, has long been known: a specimen exhibited by the Superintendent, Bangalore Division, is worthy of Honorable Mention.—*M.E.J.R.*

(7869) STENACTIS. Compositæ.—This is a showy purple flower, and well adapted for borders; it is a native of California and propagated by cuttings or dividing the roots.—*Riddell.*

(7870) STERCULIA, a genus of Plants which gives its name to the natural order *Sterculiaceæ*, which sometimes forms a section of the order *Bytteriaceæ*. The name is derived from 'stercules,' as that from 'stercus,' some of the species being remarkable for the strong and disagreeable odour of their leaves or flowers. The genus is characterised by having polygamous or monœcious flowers; calyx 5-lobed, somewhat coriaceous; petals wanting; stamens monadelphous, disposed in a short sessile or stipitate urceolus; anthers adnate, ten, fifteen, twenty, in one or two rows; solitary or ternately aggregate; ovary stipitate or sessile; carpels, follicular, five, or fewer from abortion, distinct, 1-celled, one or many-seeded, opening on the inner side: seeds disposed in two rows along the suture of the carpels; sometimes, when the carpels have opened and become spread out, they appear to be arranged along the sides of a leaf-like membrane; seeds with fleshy albumen, and flat leafy, equal cotyledons. The species consist of various-sized trees, with soft timber, which are found in the tropical parts of the world with simple or compound leaves and axillary panicles or racemes of flowers Many of them are of considerable use in the countries where they are indigenous. Like the order to which they belong several species are mucilaginous; and others yield fibre, which, from its tenacity, is made into ropes. Some yield a gummy exudation resembling tragacanth, and which is sometimes substituted for it; thus the gum called Tragacanth, which is sometimes imported from Sierra Leone, is said by Dr. Lindley to be yielded by a species which he called *S. Tragacantha*, the *S. pubescens* of others. So Dr. Roxburgh states Kuteera Gum, which is often substituted for tragacanth, to be produced by *S. urens*, a tree of the mountains of the Coromandel coast. Dr. Royle however states that the kuteera gum of many parts of India is yielded by *Gochlospermum Gossypium.—Eng. Cyc.*

It is however certain that a species of Sterculia yields a tragacanth-like gum on the west coast of America, as another does in India. Several species of this genus are remarkable for the tenacity of the fibre of their bark, which is employed for cordage, as *Myrodia longiflora* in Guiana, and *Chorisia crispifolia* in Brazil, *Dombeya umbellata* in the Isle of Bourbon, and *Sterculia Ivria* in the West Indies *Helicteres Isora* may be similarly employed in India. *Sterculia guttata* is a tree, a native of Malabar, which was first made known by Capt. Dickenson, in the year 1802. The bark of the younger parts of the tree abounds with very strong, white, flaxen fibres, of which the inhabitants of Wynaad manufacture a kind of coarse cloth. It is not usual to make use of the bark until the tenth year, when its size will be equal to that of most forest trees. The tree is felled, the branches lopped off, and the trunk cut into pieces of six feet long, a perpendicular incision made in each piece, the bark opened, and taken off whole, chopped, washed, and dried in the sun. By these means, and without any further process, it is fit for the purposes of clothing.

Sterculia villosa, called *Oadal* in Assam, is another tree of this genus, which is a native of the mountainous countries to the eastward of Bengal. Trunk straight. The bark is smooth, but fibrous. Bags are made of it. Its fibres are made into cords by the natives of the eastern frontier of Bengal, to bind wild elephants with. Of a coil of *Oadal* rope, Major Jenkins gave the following notice in the year 1847; The *Oadal* tree is very common, and the rope is made most readily; the bark, or rather all the layers, can be stripped off from the bottom to the top of the tree with the greatest facility, and fine pliable ropes may be made from the inner layers of bark, whilst the outer yield coarse ropes. The rope is very strong and very lasting—wet doing it little injury."

Oadhal is a creeper in Kemaon, with fine, strong fibres; and *Microlæna spectabilis* is

a tree found at the foot of the Himalayas, which yields fibres fit for rope-making. —*Royle Fib. Plants.*

The seeds of *S. macrocarpa* and of *S. heterophylla* are called Cola on the African coasts. In Asia, in the same way, the seeds of *S. Balanghas*, are described by Rumphius as being roasted and eaten by the natives of Amboyna, while the capsules are burned for the preparation of the colouring matter called Cassoumba. The seeds of *S. urens* and of *S. fœtida* are likewise eaten in India after having been roasted, as are those of *S. chicha* in Brazil. Those of *S. alata* are also said to be used as a cheap substitute for opium in the district of Silhet; but this statement, implying the presence of narcotic principles, requires careful examination before it can be received as a fact, as we generally find an accordance rather than so great a difference in the properties of species of the same genus.—*Eng. Cyc.*

(7871) STERCULIA: *Species.* Nar or bast from a species of the tree common in Wynaad on the higher elevations. The bast is as durable as ordinary Russian bast, but inferior to the best Russian bast.—*McIvor.*

(7872) STERCULIA ALATA. Boodh's cocoanut. A handsome tree bearing a large fruit, called Boodh's cocoanut is met with in the Tenasserim Provinces, whose winged seeds are sometimes eaten by the natives.—*Mason.*

(7873) STERCULIA COLORATA.

Bhace or karaka, Duk.

A large tree with palmated five-lobed leaves; deciduous in the cold season; flowers in March and April; carpels of a bright red, somewhat resembling the broad pod of a pea opened with the peas adhering; the tree when covered with them has a strange appearance. —*Riddell.*

(7874) STERCULIA FŒTIDA, Linn. Fetid Sterculia.

Peenata marum, Tam.	Clompan Boerong, Rumph.
Karill, Mal.	
Peenary Marum, Tam.	Gurrapa Badum Chettoo, Tel.

Grows to a very large size, with digitate leaves; deciduous in the cold weather. Flowers in March and April, of a dull crimson colour, and of an offensive odour: the seeds are roasted and eaten.—*Riddell.*

A large tree but chiefly found on the W. Coast and Mysore, where it is applied to a number of useful purposes. This is one of the trees which are believed to furnish the smaller "Poon spars," Hort. Garden. 19.—*M. E. J. R.* In the cells of this fruit there are contained certain white kernels which have a very pleasant taste intar carnem ossiculum locatur oblongo-rotundum nucleum continens candidum amaro-dulcem. "Vide *Hort. Mal. Phar. 4, page 75.* The flower has a most offensive smell and hence the Tamul name. —*Ainslie, p. 230.* The *Sterculia fœtida*, distinguished by the abominable fœtid smell of its flowers, is common on the continent of India and Java, where the fruit is used in the treatment of gonorrhœa. The leaves are deemed aperient, and a decoction of the fruit mucilaginous and astringent. The seeds are oleaginous, but are deemed unwholesome. The fœtid sterculia is not uncommon in the forests, and its seeds are eaten like filberts.—*Mason.*

The oil.

Goodira pusjun yennai, Tam.

The semi-solid oil obtained by expression from the seeds of this large jungle tree, appears to contain a large per centage of stearine, but it is doubtful if it can be obtained in large quantities; it was sent to the Great Exhibition of 1851 from Bombay.—*M. E. J. R.*

(7875) STERCULIA FOLIIS DIGITATIS.

Malay Taynga, Tam.	Conda Thankaia, Tel.
Hill Cocoanut, Eng.	

The edible seeds of this plant are eaten by the poor and are contained in follicles, each of which is nearly as large as two hands joined.—*Ainslie, page 227.*

(7876) STERCULIA GUTTATA.

Goldar, Duk.	Pee marum, Tam.

A large erect tree; leaves long petioled, villous underneath; flowers in simple terminal racemes, pubescent on both sides, outer and inner of a pale yellow colour, marked with purple spots; deciduous. Carpels the size of a large apple, three or more growing together, of a reddish colour; seeds size of a chesnut, roasted and eaten by the natives.—*Riddell. Sterculia guttata* is a native of Malabar, and was first made known by Capt. Dickenson, in the year 1802. The bark of the younger parts of the tree abounds with very strong, white, flaxen fibres, of which the inhabitants of Wynaad manufacture a kind of coarse cloth. It is not usual to make use of the bark until the tenth year, when its size will be equal to that of most forest trees. The tree is felled, the branches lopped off, and the trunk cut into pieces, of six feet long, a perpendicular incision made in each piece, the bark opened, and taken off whole, chopped, washed, and dried in the sun, by these means, and without any further process, it is fit for the purposes of clothing.—*Royle.* This, says Wight, is a large tree; but I am not acquainted with the timber, no specimen having been sent with the leaves.—*Wight.* From Wynaad, Captain Dickenson sent the seeds to the Botanic garden in 1802, and the young trees reared therefrom blossomed for the first time in December 1809. They were then about twenty feet high, and the trunk twenty-one inches in circumference four feet above the ground. The bark of this tree, the Malabars convert into a flaxy substance of which the natives of the lower coast of Wynaad contrive to make a sort of clothing,

which derives its name from the first process of its manufacture, viz., the chopping the bark into small pieces, from suragoonoo, to cut. It is not customary to manufacture the bark until the tenth year, when its size will be equal to that of most forest trees.—*Rhode M. S. S.*

(7877) STELLARIA MEDIA.

Kaaray Munthu-keeray Tam.

Chickweed. This English weed is used by the natives on the Neilgherries as a pot herb, eaten alone, and mixed with others, probably introduced.—*Jaffrey.*

(7878) STERCULIA PARVIFLORA: small flowered Sterculia. Abundant in the jungles of Ajmeer.—*Gen. Med. Top. p.* 202.

(7879) STERCULIA URENS. Byttneriaceæ, Roxb. c. 24 Stinging Sterculia.

Vellay pootallie marum, also Kavali, Tam.	Bulee, Beng. Kateria kooli, also Kur Kutila, Hind.

A large tree, a native of the mountainous countries on the Coast of Coromandel, Hindoostan &c. common also in the Ajmeer hills, and in Kotah.—*Med. Top. p.* 201. Leaves round, cordate and five-lobed; deciduous in the cold weather; flowers in February and March, very small; the carpel is covered with rigid bristly hairs, which puncture like the Mucuna pruriens. The bark of the trunk is white, and gives the tree a dead appearance. —*Riddell.* The kutila gond, is obtained in great abundance from this tree; the seeds of the stinging pods are palatable when roasted and very wholesome: many bushels must be yielded by one large tree, and the poor in famines should collect the seeds for food: the star-shaped pods are covered with stinging pubescence. The wood of this tree is soft and spongy, except towards the centre of large trees, where it is reddish. Mr. Rohde does not know of any use it is put to except to make fuel. I observed, he says, that the water on which I kept the green branches for examination became thick, like clean glutinous jelly. Bark exceedingly astringent, tinges the spittle reddish. It yields a gum not unlike Tragacanth, and has been sent to London as such, but the artists, who used the gum, did not find it answer. The seeds are roasted and used by the natives as an article of diet and also as a dainty.—(*Roxb.*) *Rhode M. S. S.* The gum, which exudes spontaneously during the hot season, occurs in large light brown transparent tough masses. Immersed in water they swell like a jelly, but do not dissolve but by protracted boiling. The solution is not adhesive, and is destitute of the thickness of solutions of ordinary gum. The uses of this gum are very limited: the want of adhesiveness renders it unsuitable for the arts, while its difficult solubility renders it inferior to most other gums for medicinal purposes. A similiar gum called Kutira is afforded by the Cochlospermum gossypium of Coromandel, Travancore, and Ceylon, a large tree, with bright yellow flowers. For an account of properties and use of the true tragacanth gum, which the Kutira much resembles, see *Astragalus*, also *kuteera*. The roasted seeds, which contain starch and fixed oil, have much the flavour of chestnuts, and are eaten by the natives of this country.—*O'Shaughnessy.* The wood of this very large tree is soft and loose grained, only fit for the most common purposes. The leaves when soaked in water have the property of rendering it ropy and glutinous. The bark yields a gum resembling gum tragacanth. —*Wight.*

The Gum.

Katila ka gond, Hind. | Tshaw, Burm.

The white transparent gum of the kur tree: tasteless and similar in property to tragacanth: swells exceedingly when placed in water but does not dissolve: in Medicine considered cooling and astringent, and given, in Ajmere, in "dai" and "luddoo."—*Gen. Med. Top.* Six species of *Sterculia*, four of which, *viz. Sterculia ramosa*, *S. fœtida*, *S. campanulata*, *S. piperfolia*, are very plentiful throughout the Pegu Province, yield a gum which is known in the bazars of Bengal under the name of Kotheela. The other two species, *Sterculia balangas* and *S. calorata*, are not so plentiful. This gum is probably analogous to the *Tragacanth*, which Dr. Lindley states is obtained from a species of *Sterculia* at Sierra Leone.—*McClelland.*

(7880) STERCULIA VILLOSA. A large tree; leaves palmated, five or seven-lobed.—*Riddell.*

(7881) STERCULIACEÆ, *Sterculiads*, a natural order of Plants belonging to the syncarpous group of Polypetalous Exogens. The plants belonging to this order are trees or shrubs, with alternate, stipulate, simple, often toothed, leaves, with a variable inflorescence, and a stellate pubescence. The calyx is either naked or surrounded with an involucre, consisting of five sepals, with a valvular or nearly valvular æstivation; five petals, hypogynous often saccate at the base: stamens definite or indefinite and monadelphous; anthers 2-celled; the pistil consists of five carpels, often surrounding a columnar gynophore; fruit a capsule with three or five cells; seeds often winged, sometimes woolly; albumen oily or fleshy, and embryo straight; cotyledons either flat and plaited or rolled round the plumule.

The order thus defined includes several groups of plants, which have by many writers been made to form distinct orders. Sterculiaceæ are most nearly allied to Malvaceæ from which they differ in the possession of 2-celled anthers. From Dipteraceæ and Tiliaceæ, to which they are allied by the valvate æstivation of the calyx, they differ in the possession of monadelphous stamens. The subdivisions of this order are marked by very evident peculiarities of structure.

Helictereæ have an irregular calyx and corolla.

Sterculieæ, no petals and definite stamens placed at the end of a long column.

Bombaceæ, a calyx with a ruptile dehiscence usually woolly seeds, and the cells of the anthers anfractuose.

Dombeyæ, a part of the stamens sterile, and flat; well formed petals.

Byttnerieæ, a part of the stamens steriles, and small petals bagged at the base.

Lasiopetaleæ, a petaloid calyx and rudimentary petal.

Hermannieæ, spirally twisted petals with only five stamens, and those opposite the petals.

Sterculiaceæ, are natives of India, Australia, the Cape of Good Hope, and South America with the West Indies. Most of its subdivisions have however a very definite Geographical range.

Sterculiaceæ, are found in India, and equinoctial Africa. The genus Sterculea contains many species that are used as food or medicines.

Byttnerieæ, are principally natives of South America and the West Indies, about one-seventh of the species are found in the East Indies, and the same proportion in Australia. To this group belongs the plant that produces the cocoa [Theobroma] of commerce. These plants, like the whole of the order and its allies, abound with mucilage and are often used in medicine as demulcents. The fruit of Guazuma ulmifolia possesses a mucilaginous pulp and is eaten in Mexico by man, but principally employed for feeding cattle. The bark of this plant is bitter, and is said to be serviceable in the horrible disease called Elephantiasis.

Hermannieæ—Two-thirds are found at the Cape of Good Hope; the remainder are natives of the East and West Indies, South America, and the islands of the Pacific. The species of *Waltheria* abound in mucilage, and are used in medicine as demulcents.

Dombeyæ are all African, East Indian, or South American. Their properties are similar to the preceding. One of the species, *Wallichia spectabilis*, forms a handsome tree, approaching the Linden, and points out a relation between this order and *Tiliaceæ*.

Lasiopetalæ are found entirely in Australia, and possess no remarkable properties. Further information on the properties of plants of this order might be arranged under BOMBACEÆ, ADANSONIA, STERCULIA, and THEOBROMA.—*Eng. Cyc.*

(7882) STEREOSPERMUM. Of this genus Wight gives, in Icones, Stereospermum chelonoides, 1341; suaveolens, 1342.

(7883) STEREOSPERMUM CHELONOIDES. *Bignoniaceæ*, Icon. 1341.

Velapauthrie marum, TAM.

Usually pronounced padrie marum, the flowers are very fragrant, and the tree a very handsome one, though not large. It is probable there is some confusion in the specimens, as the proper padrie marum is reddish, and this is called the white padrie, though the specimens seem to be the same as the other. This may easily happen, as the trees are very like, being principally distinguished by the colour of the flowers; yellowish on this, brownish purple in that. Hence, perhaps the two names, black and white pantherie. This is said to be the stronger wood of the two.—*Rohde.*

(7884) STEREOSPERMUM SUAVEOLENS. *Bignoniaceæ*, Icon. 1341.

Padrie marum. TAM. | Ooloomanthiree Mara. CAN.

A middle sized three with pinnate leaves, and panicled inflorescence, very fragrant wood (according to Wight,) strong and elastic, said to be fitted for making bows. Wight No. 63, Mysore 38.—*M. E. J. R.* A considerable tree, frequent in the Walliar jungles, wood strong and elastic (said to be fitted for making bows), wood dark and good.—*Wight.*

(7885) STERNIDÆ, the name of a family of Web-footed, long-winged Birds, which are commonly known as Sea Swallows and Terns.—*Eng. Cyc.*

(7886) STEVIA PURPUREA. COMPOSITÆ. PUREA. These are pretty, small flowering plants, natives of new Spain and Mexico, propagated by seed, cuttings and division of the roots in any good garden soil.—*Riddell.*

(7887) STILAGINACEÆ, a small natural order of plants, belonging to the rectembryose group of Apetalous Exogens. They are trees or shrubs, with alternate simple stipulate leaves, the stipules being deciduous. The flowers are unisexual, mostly seated on amentiform spikes or racemes. Calyx 3-5-parted; stamens two or more, arising from an enlarged receptacle with capillary filaments and 2-lobed anthers dehiscing transversely; ovary superior, stigma sessile; fruit a drupe with one seed, which is pendulous; the embryo is green, lying in the midst of fleshy albumen. The species of this order are all of them natives of the East. In its relations this order is obscure. It has some resemblance to *Urticaceæ*, from which it is distinguished by its enlarged disc, its peculiar anthers, and unelastic filaments. In these characters it resembles *Hensloviaceæ*, but they differ from this order in having but one carpel and a single seed. Many of the fruits of this order have a pleasant subacid flavour, and are eaten by the natives of the East Indies.—*Eng. Cyc.*

(7888) STILAGO, a genus of Plants sometimes united with, at other times separated from the genus *Antidesma*, belonging to the natural family *Antidesmeæ*, which by some botanists is called *Stilaginaceæ*. The species are few in number, forming shrubs and moderate-sized trees, which are found in Madagascar and Mauritius,

as well as in some of the Indian islands, and in India, where the species extend even to northern parts. The genus is characterised by having dicœcious flowers, the male having a 3- or 5-parted perianth. Stamens 2, 3, or 5, inserted in an annular disc with the rudiment of an ovary. The female flower has the perianth of the male, and the disc surrounding the base of the ovate single-celled ovary. Ovules 2, pendulous from the apex of the cell. Stigma sessile, 3- to 5-rayed. Drupes 1-seeded, crowned by the stigma, with the nut rugose both inside and out. Albumen fleshy, scrobiculate. Cotyledons foliaceous. Embryo inverse. The flowers are arranged in axillary catkin-like spikes. The leaves of *Antidesma alexiteria* are employed in the Mauritius as an antidote against snake-bites. Cordage is made with its bark, as well as with that of *A. Zeylanica* in Ceylon. The small fruits of both species are eaten and preserved: the fruits of *A. pubescens* (*Stilago*), *Bunias*, and *Diandra*, are eaten by the natives of India.—*Eng. Cyc* Wight, in l cones, gives Stilago Bunias, 819; lanceolaria, 766; pubescens, 821; tomentosa, 767-8.

(7889) STILAGO DIANDRA, *Antidesmeæ*, R. C. 166.

Asary poolie-marum TAM. | Tengurce, BENG.
Tella Goomoodoo, TEL.

A tree, a native of the mountainous parts of the Circars. Roxburgh says the wood of this tree is put to various uses, but seems himself to be but little acquainted with it, judging from a branch specimen, nearly white at first, but becoming brownish by exposure to the air.—*Wight* The berries are eaten by the natives when ripe. The wood serves for various uses.—*Rohde M.S.S.*

(7890) STILLINGIA, a genus of Plants belonging to the natural order *Euphorbiaceæ*, so named in compliment to Dr. Stillingfleet, known as an English botanist. The genus now includes the species of *Sapium*, and is distinguished by one of its species being the famous Tallow-Tree of China. The generic character of *Stillingia* is; Flowers monœcious; males aggregate; calyx cup-shaped, crenulate, or bifid; stamens two, inserted; filaments united at the base; anthers opening outwards; female flowers solitary; calyx tridentate or trifid; ovary sessile, 3-celled, each cell with a single ovule; style short, thick; stigmas three, simple, spreading; capsule globose, tricoccous; cocci single seeded. The species consist of milky trees or shrubs found in the tropical parts of Asia and America, and likewise in the islands of Bourbon and Mauritius. The leaves are alternate, petiolate; petioles bi-glandular at the apex. Male flowers usually crowded in terminal spikes, supported at the base by a bi-glandular bract. The female flower is commonly below the spike, sometimes sub solitary on another branch.—*Eng. Cyc.*

(7891) STILLINGIA SEBIFERA, the Tallow-Tree of China, at one time attracted considerable attention, and was introduced into various European colonies, in the East and West Indies. It may be met with in English hothouses. Dr. Roxburgh describes the plant as common in his time about Calcutta, but that it did not yield any useful product, and was therefore only an ornamental tree, being in flower and fruit most parts of the year. It is found in China on the borders of rivulets, and is also cultivated. It grows to the height of a pear-tree, having a trunk and branches like the cherry, and foliage like the black poplar, but which turns red in autumn. It was met with in Chusan by the late expedition, and seeds sent home by Dr. Cantor, which have been sown in the Horticultural Society's Garden at Chiswick. The fruit of this tree furnishes the Chinese with candles, and oil for their lamps. The seed-vessels and seeds are bruised and then boiled in water. The fatty particles rising to the surface are skimmed off, and on cooling condense into tallow. To give it greater consistence some wax is added, together with linseed-oil in the proportion of three parts to ten of the tallow. The candles made with it are beautifully white. Sometimes they are coloured red by the addition of vermilion. These candles are sometimes said to be coated with wax procured from another Chinese tree (probably *Ligustrum lucidum*,) which forms an external crust and prevents them running. This tallow is also employed in medicine instead of lard.—*Eng. Cyc* The kernel of the seeds of the tallow tree of China, Stillingia sebifera, says Simmonds, contains an oil, which, when expressed, consolidates through the cold to the consistence of tallow, and by boiling, becomes as hard as bees' wax. The plant also yields a bland oil. A similar fatty product is obtained from a shrub in British Guiana the Myristica (Virola) sebifera. *Simmonds* The celebrated tallow tree (Stillingia) symmetrical shaped tree, is a native of all the eastern provinces of China, and resembles the aspen in the form and colour of the leaf, and in its general contour —*Williams, Middle Kingd. page* 282. According to Mr. Williams the tallow tree (*Stillingia sebifera* occurs over all the eastern part of China, and when fully grown is a beautiful tree, resembling the aspen in its shape and foliage; it would form a valuable addition to the list of shade trees in Britain. The seeds grow in clusters like ivy berries, and are collected in November; when ripe, the capsule divides, and falling off discovers two or three kernels covered with the pure white tallow. When the tallow is to be prepared, these are picked from the stalks and put into an open wooden cylinder with a perforated bottom, in which they are well steamed, over boiling water. In ten or fifteen minutes, the tallow covering the seeds becomes soft, and they are then thrown into a stone mortar and gently beaten with a mallet t

detach it. The whole is then sifted on a hot sieve, by which the tallow is separated from the kernels, though containing the brown skin which envelops the latter, and presenting a dirty appearance. The tallow in this state is inclosed in a straw cylinder, or laid upon layers of straw held together by iron hoops, and subjected to pressure in a rude press from which it runs clear in a semifluid state, and soon hardens into cakes. The candles made from it become soft in hot weather, and are sometimes coated by dipping them in colored wax.—*Williams' Middle Kingdom, Vol.* II, *page* 107. The tallow tree (Stillingia sebifera) is abundant in the valleys of Chusan, and large quantities of tallow and oil are yearly extracted from its seeds: tallow mills are erected in several parts of the island for this purpose. The Laurus Camphora, or camphor tree, is also abundant, but no camphor is extracted or exported from the island. *Fortune's Wandering, page* 67. At another place, he says, for the following account of the Chinese method of extracting the tallow from the seeds of the *Stillingia Sebifera*, I am indebted to Dr. Rawes, of the Madras army, who was some time a resident in the island of Chusan; "The seeds are picked at the commencement of the cold weather, in November and December, when all the leaves have fallen from the trees, this I saw at Sing-kong when out shooting in the sah-hoo-valley close by our quarters, through the village. The seeds are in the first place taken to the building where the process of making the tallow is carried on, and picked and separated from the stalks. They are then put into a wooden cylinder, open at the top, but with a perforated bottom. This is placed over an iron vessel (about the same diameter or rather larger than the wooden cylinder, and about six or eight inches deep) containing water, by which means the seeds are well steamed, for the purpose of softening the tallow and causing it more readily to separate. The furnace I saw had four or five iron vessels in a row, was about three feet high, four or five feet broad and eight or ten feet long. The fire was placed at one end and fed with the husk of the rice, dry grass, and such like cheap materials which make a great flame, and the flue was of course carried directly under the whole of the iron vessels. "When the seeds have steamed ten minutes or a quarter of an hour, they are thrown into a large stone mortar and are gently beaten by two men with stone mallets for the purpose of detaching the tallow from the other parts of the seed. They are then thrown upon a sieve heated over the fire, and sifted, by which process the tallow is separated, or nearly so, although they generally undergo the process of steaming &c. a second time that nothing may be lost. The other part of the seed is ground and pressed for oil. "The tallow now resembles coarse linseed meal, but with more white spots in it and derives its brown colour from the thin covering over the seed (between it and the tallow) which is separated by the pounding and sifting. In this state it is put between circles of twisted straw, five or six of which are laid upon each other, and thus forming a hollow cylinder for its reception. When this straw cylinder (we may call it so) has been filled, it is carried away and placed in the press, which is a very rude and simple contrivance, but which like every thing Chinese, answers the purpose remarkably well. The press consists of longitudinal beams of considerable thickness, placed about a foot and a half, or two feet, asunder, with a thick plank at the bottom, forming a kind of trough, and the whole is bound together with iron. The tallow is pressed out by means of wedges driven in very lightly with stone mallets, and passes through a hole in the bottom of the press into a tub, which is sunk there to receive it. It is now freed from all impurities, and is a semifluid of a beautiful white colour, but soon gets solid, and in cold weather is very brittle. The inside of the tubs which collect the tallow are sprinkled or dusted over, with a fine red earth, well dried, which prevents the tallow from adhering to their sides. It is thus easily removed in a solid state from the tubs, and in this condition the cakes are exposed for sale in the market. As the candles made from this vegetable tallow have a tendency to get soft and to melt in hot weather, they are commonly dipped in wax of various colours as red, green and yellow. Those which are intended for religious purposes are generally very large, and finely ornamented with golden characters. The cake, or refuse, which remains after the tallow has been pressed out of it, is used for fuel, or to manure the land, and so is the refuse from the other part of the seeds from which oil is extracted.—*Fortune.*

(7892) STIPA, a genus of Grasses belonging to the tribe *Stipaceæ*. It has stalked florets, the paleæ coriaceous, the inner entire. *S. pennata*, the only British species, has a very long twisted feathery awn, with a glabrous base. It is a very beautiful plant, and is common in English gardens. Found on rocks in Long Seadale near Kendal.—*Eng. Cyc.* This beautiful species of grass is grown chiefly in gardens for the sake of the beautifully feathered heads.—*Riddell*

(7893) STIZOLOBIUM, a genus of Plants which was so named by Persoon, from στίζω to prick, and λοβός, a lobe or pod, from the pods of the several species being covered with hispid hairs. The species have now been removed chiefly to *Pachyrhizus* [DOLICHOS] and to *Mucuna*; of the latter of these *Stizolobium* now forms a sub genus. The principal species are mentioned under COWITCH and MUCUNA. Cowitch is no doubt a corruption of the Hindustanee name Kiwach, which is the *Mucuna prurita* of Hooker,

indigenous in various parts of India, but usually confounded with *M. pruriens*, a native of the West India Islands. The Indian *M. prurita* is distinguished by its smaller leaves, its more obtuse leaflets, the middle one being more truly rhomboidal, its flowers more constantly in threes, and by its legumes being much broader, compressed, and free from any raised line on the back of the valve, whilst in the American *M. pruriens* the pods are narrower, terete, and keeled on the valves. Another valuable but little known species is *M. utilis*, the Bois Noire of the islands of Mauritius and Bourbon, and thought to be a native of Arabia. It is universally employed in the above islands for enriching the soil for the cultivation of sugar. The thick covering of herbage with which the soil becomes covered, must be useful in preventing the soil from becoming parched, while the whole crop, being afterwards ploughed in, is found to be eminently useful in enriching the soil. The seed has been introduced into India and is spreading over the country.—*Eng. Cyc.*

(7894) STIZOLOBIUM ALTISSIMUM.—Assam Bean.

Kalee Seem. Duk.

This bean is grown like most others, and may be first sown at the commencement of the rains and continued during the cold season.—*Riddell.*

(7895) STOMAPODA. M. Milne-Edwards comprises in the order *Stomapoda* all the Podophthalmous *Crustacea* which are deprived of thoracic branchiæ lodged in interal cavities. This division is entirely composed of Swimming Crustaceans, whose body is elongated, and whose general form often approaches closely to that of the Macrourous Decapods; but in those animals the concentration of the rings of the head and thorax is carried less far.

(7896) *Lucifer Typus.*—This species differs from the only other, *Reynaudii*, (which was found in the Indian Ocean by M. Reynaud) in the form of the median piece of the caudal fin, which is lamellar, and without any notch below, in the more considerable length of the middle blades, and in the apparent absence of a separation between the carapace and oculiferous prolongation.

(7897) *Squilla.* (Rondeletius).

(7898) *Squilla Maculata.* Length from 10 to 12 inches. It inhabits the Asiatic seas.

(7899) *Squilla Stilifera.* Length about 3 inches. It is a native of the island of Mauritius.

(7900) *Gonodactylus* (Latreille).

(7901) *Gonodactylus Chiragra.* Length about 3½ inches. The species are found in all the seas of warm climates: the Mediterranean, American coasts, Seychelles Islands, near Trincomalee, and Tongataboo.

(7902) *Gonodactylus Scyllarus.* Length about 4½ inches. It is found in the Indian Seas and on the coasts of Mauritius.

(7903) STONE. *Working in stone*, polishing the hardest surfaces, engraving its surface with imperishable records, and sculpturing it into various forms, even excavating gigantic temples out of the solid rock, are all departments of sculpture and engraving to which the Hindoos have paid attention from the earliest times; and their buildings are conspicuous for a quality for which those of Egypt have often been admired, that is, the exquisite polish and glass like appearance of some of the hardest granite &c. Kennedy has fortunately given us an account of the process by which they effect this. "The tools," he says, "which the Hindoos use are a small steel chisel and an iron mallet. The chisel, in length, is not more than about twice the breadth of the hand of the Hindoo workman; which, as is well known, is very small; and it tapers to a round point like a drawing-pencil. The mallet, also in iron, a little larger than the chisel, but not weighing more than a few pounds. It has a head fixed on at right angles to the handle, with only one striking face, which is formed into a tolerably deep hollow and *lined with lead.* With such simple instruments they formed, fashioned, and scooped the granite rock which forms the stupendous fortress of Dowlatabad, and excavated the wonderful caverns of Ellora; for it seems by no means probable that the Hindoo stone-cutters ever worked with any other tools." Dr. Kennedy adds, "The traces of the pointed chisel are still visible on the rocks of Dowlatabad, as they are also on some of the great works of Egypt. The stone having been brought to a smooth surface, it is next dressed with water in the usual way, and is then polished in the following manner. A block of granite, of considerable size, is rudely fashioned into the shape of the end of a large pestle. The lower face of this is hollowed out into a cavity, and this is filled with a mass composed of pounded corundum-stone, mixed with melted bees-wax. This block is moved by means of two sticks, or pieces of bamboo, placed on each side of its neck, and bound together by cords, twisted and tightened by sticks. The weight of the whole is such as two workmen can easily manage. They seat themselves upon, or close to, the stone they are to polish, and by moving the block backwards and forwards between them, the polish is given by the friction of the mass of wax (and lac?) and corundum."—*Royle* Nearly the same materials, and with a still greater degree of success are employed in polishing such delicate articles as beads and bracelets; elegantly shaped cups, or the models of cannon. Of the processes employed a very interesting account, which is published in the "Illustrated Catalogue," is given by Mr. Summer of Cambay. The stones

are first fixed on a steel spike, and there roughly rounded with an iron hammer, and then polished with a composition of lac and corundum variously applied. The holes are bored with a steel drill, tipped with a small diamond. Cups and saucers and similar hollow articles, are wrought, according to the required external shape on the steel spike, and a rough polish given on the rough polishing stones. The cavity is formed by the diamond-tipped drill to the depth of one-fourth of an inch all over the space, until it exhibits an honey-combed appearance; the prominent places round the holes are then chipped away; and this process is repeated until the depth and form desired are obtained. They are then polished upon prepared moulds of convex forms, and of the same composition as the polishing-plates which are attached to the turning-wheel.—*Royle, Arts &c. of India, page* 513 *and* 515.

(7904) STORAX.

Usteruck, Salajet, Meah, Arab.	Storax, Fr.
Storace, It.	Stryax-broom, Ger.
Styrax, Lat.	Azumbar. Sp.

The produce of a tree (*Styrax officinale*), growing in the South of Europe and the Levant. It is usually met with in tears, which is pure; and in lumps or *red storax*, which is mixed with saw dust and other impurities. Storax has a fragrant odour, and a pleasant, sub-acidulous, slightly pungent, and aromatic taste; it is of a reddish brown colour, and brittle. (*McCulloch.*) —*Faulkner.*

(7905) STORAX LIQUID, Sillarus; Rose Mallows.

Sillarus, Miati-lubni Meih-katar, Arab.	Sillarus Meih-Seela, Guz, Hind. Pers.

Liquid storax is usually more or less opaque, of the consistence of bird-lime, grayish colour, warm balsamic taste, and peculiar vanilla-like odour, if pure. Small quantites are imported annually into Bombay from Suez and the Arabian Gulf in skins; it is re-exported to England and China under the designations of Rose Mallows (Rosa mallos) and Sillarus, in barrels of about four imperial gallons capacity each.—*Faulkner.* See Ambar Liquid, also Liquidambar.

(7906) STRAWBERRY, the English name of the fruit and plant of the *Fragaria*, a genus of plants belonging to the natural order *Rosaceæ*. The fruit of the *Fragaria* is one of the most delicious of England's summer fruits. The name *Fragaria* is derived from the Latin *Fragum*: and the English name from the practice in that country of cultivating the plant with straw surrounding it. The genus *Fragaria* is known in its family by possessing a calyx with a concave tube, the limb of which is 10-parted, and the outer 5 segments accessory; 5 petals; stamens and carpels indefinite, the latter placed upon a fleshy and succulent receptacle, forming the juicy and succulent part of the fruit. The species are perennial plants, throwing out runners; the leaves are trifoliate, each leaflet being coarsely toothed; the receptacle on which is seated the carpels, and which is called the fruit, is round, and assumes a variety of colours from a scarcely perceptible pink to a dark red. Several species of this genus have been described. Linnæus gave only two; but Wildenow admitted eight; and Don, in 'Miller's Dictionary,' enumerates fourteen. Duchesne, who is followed by many French botanists, makes only two species, and makes the species of other writers varieties of these. All of them are natives of temperate or cold climates; and are found in Europe, America, and the mountains of Asia.—*Eng. Cyc.* Mr. Mason raised very fine strawberries in his garden at Tavoy, but the plants required considerable care.—*Mason.* The yellow flowered Indian Strawberry in the Terai ascends 7500 on the mountains.—*Hooker Him. Jour., p.* 395.

(7907) *Fargaria Chilensis*, Chili Strawberry, is a native of South America, both in Chili and Peru.

(7908) *Fragaria Collina*, the Hill Strawberry, has the sepals erect after flowering, and the hairs on the peduncles and calyx erect. This species is a native of Switzerland and Germany, and is characterised by its producing green fruit. The varieties of strawberries which are called Green are the produce of this species. In flavour and size they are only a second-rate strawberry.

(7909) *Fragaria elatior*, the Hautbois Strawberry, has the sepals reflexed on the peduncle, the hairs of the peduncles and petioles extending horizontally. It is a native of North America, and is occasionally found in groves in the south of England. The shape, size, and colour of the fruit of the Hautbois are subject to great varieties, according to its mode of cultivation. It is the parent of a great number of sorts known in gardens, most of which, when properly managed, produce fruits of a first-rate kind.

(7910) *Fragaria grandiflora*, large-flowered Strawberry, is a native of Surinam, and has furnished English gardens with the sorts called Pine strawberries.

(7911) *Fragaria Majanfea*, the Majanfe of the French.

(7912) *Fragaria vesca*. Wood or Alpine Strawberry, has plicate leaves, pilose beneath; the sepals reflexed and the hairs on the peduncle pressed down. It is found wild in woods and on hill-sides throughout Europe, and is abundant in Great Britain. Duchesne describes eight varieties of this species, mostly characterised by the different form of the fruit or fleshy receptacle. Many of these produce the cultivated varieties which are known in gardens. The *F. v. semperflorens* produces the Red, the White, the American, and Danish Alpine strawberries, all of which are of a fine flavour, and greatly valued.

F. v. minor produces the Red Wood-Strawberry, or Frasier d'Angleterre, and the White Wood-Strawberry, both very fine kinds. To the *F. v. flagellis* belongs the Red and White Alpine Bush-Strawberry, but these do not produce so good fruit as the last.

(7913) *Fragaria Virginiana*, the Virginian Strawberry.—*Eng. Cyc.*

Dr. Riddell gives the following instructions on the cultivation of strawberries in the Dekhan :—

General Observations.—"*The Strawberry* multiplies itself from runners and suckers; the old plant, after it has ceased bearing, throwing them out. As soon as the rains have set in, these runners may be removed into a nursery bed, for their being more easily looked after, and should have the space of nine or ten inches allowed between them: they will throw out other runners, the whole of which may be separated and transplanted at the proper season. They thrive best in a light soil with good old stable and vegetable manure at first, and as soon as they show a disposition to flower, may have old goats' or sheep's manure added around each plant, a couple of a double handsful being sufficient. In no part of the Deccan, should the plants be put out for fruiting before the close of the rains, the latter part of September being quite early enough. Suckers which I planted for experiment at the commencement of August, grew to a good size, and did nothing for ten or twelve weeks but throw out suckers, which were continually removed, and after all fruited badly: the finest and most prolific crop were got from suckers put out in the beginning of October. Some strawberries were gathered in November from the plants put out in August, but they were so few as in no way to induce me to try the experiment again. Varieties can only be procured from seed; and to procure the seed, select the finest ripe fruit, rub it on a sheet of paper, and dry it. When the rains commence, soak the seed in water, reject all that float, the remainder sow in baskets in a light loam, when they will be fit to remove in about six weeks, and should be put in other baskets four or five inches apart, and taken care of until ready to be transplanted into beds, where they are to remain. As these plants throw out suckers very fast, they must be constantly looked after, and removed unless you have a scarcity of plants. They will commence bearing in six months from the time of sowing the seed. You may, as soon as the rains have ceased, put your suckers that have rooted into square beds, each not less than one foot apart, five in a row: this will give you twenty-five in each bed—as many as can be easily looked after and gathered without trampling on the bed and thereby injuring the plants. When the earth is of a clayey consistence, I have seen the strawberry cultivated on ridges. Some think this is a good plan, but I prefer the beds: however, it can be easily tried. It is sometimes necessary, in consequence of flooding the beds, to put tiles under the fruit to keep it clean, but it also attracts the notice of the birds: if straw or grass be used, then the chances are that white ants destroy your plants. This it is that makes some persons prefer the ridge system of growing, as they say the fruit is cleaner in consequence: all I know is, that fine fruit may be grown either way; and if on ridges, the same distance must be allowed between the plants as in beds—and even in the latter the plants may be put on raised cones of earth. The common vegetable manure is all that is required at first until near flowering, when a handful or two of goat's or sheep's dung should be put round the plant, opening the earth and scraping it together. Water during the evening and very early in the morning."—*Riddell.*

(7914) STREPTOCARPUS. BIGNONIACEÆ. This is a handsome plant from the Cape of Good Hope, produces abundance of pale, purple flowers, it requires a good garden soil, and is increased by seed.—*Eng. Cyc.*

(7915) STRIGIDÆ. The Owls. This family of Birds, includes the Nocturnal Birds of Prey. The following table gives Mr. Swainson's arrangement for the entire family.

	Genera.
1. Typical Group.—Ears large, operculated, no egrets,.....	*Strix.*
2. Subtypical.—Ears smaller, no operculum, egrets,.....	*Asio.*
Ears small, no egrets or operculum, disc imperfect.	
3. Aberrant.—Head small, claws feathered, tail short.....	*Nyctea.*
Head large, claws naked, tail moderate.....	*Nyctipetes.*
Head small, claws feathered, tail wedged.....	*Surnia.*

Mr. G. R. Gray makes the *Accipitres Nocturni* the second sub-order of his first order *Accipitres*. His third family, the first of that suborder, is formed of the *Strigidæ*, which are thus subdivided by him :—

Sub-Family 1.—*Surninæ*,

Genera.—*Surnia*, Dum. (*Syrnia*, Steph., *Strix*, Gm.); *Accaba*, Wagl. (*Surnia*, Cuv., *Strix*, Shaw); *Nyctea*, Steph. (*Noctua*, Cuv., *Nyctia*, Sw.); *Athene*, Boie (*Nyctipetes*, Sw., *Strix*, Daud.); *Huhua*, Hodgs.

Sub-Family 2.—*Buboninæ*.

Genera.—*Scops*, Sav., (*Scops* Sav., *Asio*, Briss., *Otus*, Less., *Strix*, Linn.); *Lophostrix*, Less., *Ketupu*, Less. (*Cultrunguis*, Hodgs., *Strix*, Gm.,); *Bubo*, Sibb. (*Feliceps*, Barr., *Asio*, Antiq., *Ulula*, Bonap *Heliaptex*, Sw., *Ascalaphus* J. Geoff., *Strix*, Linn.).

Sub-Family 3.—*Ululinæ*.

Genera.—*Syrnium*, Sav., (*Scotiaptex*, Sw., *Ulula*, Briss., *Strix*, Linn.,); *Otus*, Day (*Asio*,

Briss., *Brachyotus*, Gould, *Strix*, Linn. ; *Urrua*, Hodgs. ; *Nyctalops*, Wagl. ; *Ulula*, Cuv. (*Strix* Gm.) ; *Glaucidium*, Boie (*Stix*, Linn., *Noctua*, Cuv., *Athene*, Boie) ; *Nyctale*, Brehm. (*Scotophilus*, Sw., *Nudipedes* and *Ptilipedes*, Less., *Strix*, Bechst., *Athene*, Boie) ; *Ninox*, Hodgson.

Sub-Family 4.—*Striginæ*.

Genera.—*Strix*, Linn. ; *Pholidus*, J. Geoff. (*Strix*, Horsf,) ; *Bulaca*, Hodgson.

The geographical distribution of this family is very wide ; extending as high as the Polar Sea, where *Stryx Nyctea* is recorded by Sabine as having been seen on the islands in the summer months, and by Sir James Ross as having been observed about Victoria Harbour throughout the winter, where several pairs had bred in the preceding autumn ; and as low at least as Port Famine in the Straits of Magellan. *Strix rufipes* and *S. nana*, &c., King). Species are found in Europe, Asia, Africa, America, and in Australia. They feed on birds and quadrupeds, and even fish (in the case of *Strix nyctea* and *S. flammea*), according to the size of the species. Hares, partridges, grouse, and even the turkey, are attacked by the larger horned owls of Europe and America ; while mice, shrews, small birds, snakes, and crabs suffice from the inferior strength of the smaller *Strigidæ*. Mr. Yarrell states that the Short-Eared Owl (*Strix brachyotus*) is the only bird of prey in which he ever found the remains of a bat.

(7916) *Strix flammea*, the common White or Barn-Owl, is the Effraie, Fresaie, and Petit Chathuant Plombé of the French ; Barbagianni, Alloco Commune e Bianco of the Italians ; Schleierkauz, Perlschlierkautz, and Perl-Eule of the Germans ; De Kerkuil of the Netherlands ; Barn-Owl, White Owl, Church Owl, Gillihowlet, Howlet, Madge-Howlet, Madge-Owl, Hissing-Owl, and Screech-Owl of the English ; and Dylluan Wen of the Welsh. The upper parts are bright yellowish, varied with gray and brown zig-zag lines, and sprinkled with a multitude of small whitish dots ; face and throat white ; lower parts in some individuals rusty-white, sprinkled with small brown dots ; in others bright white, marked with small brownish points ; in others again without the slightest appearance of spots ; feet and toes covered with a very short down, more scanty on the toes : iris yellow. Length about 13 inches. In the female all the tints are brighter, and more developed. The young are covered with a thick white down, and remain long in the nest. Mr Blyth states that the first set of feathers grows very slowly, and is not moulted till the second autumn.

Varieties.—Whitish, or entirely white.

This bird is common in England and Ireland, less common in Scotland. Not common in the Orkneys, but present in some of the islands. Found in Denmark, but said not to inhabit Sweden or Norway ; generally spread over temperate Europe : found in Madeira ; common in Lorraine ; extending in Africa from the north to the Cape of Good Hope ; met with in India, Japan, and Australia.

(7917) *Strix badia*, Horsf., Wowo-wiwi, or Kolongwiwi of the Javanese, is an Asiatic species. Dr. Horsfield states that this species, whose head is proportionally large, has a general resemblance to *S. flammea* in the distribution of its colours and external marks. The upper parts are, he observes, generally dark, and the lower of a paler hue. The neck is surrounded by a loose ornamental collar ; the plumes encircling the eyes are rigid, and disposed with perfect regularity, and the legs are entirely covered. A resemblance also exists, he adds, in the lustre of their covering. It is a native of Java, in the closest forests of the district of Pugar, and the ranges of low hills south of the capital of Surakarta. (Horsfield.) The habits of this species are nocturnal. Dr. Horsfield speaking of *S. Javanica* (which, he says, his specimens show to be merely a variety of *S. flammea*), remarks, that it is the only species of this division which is occasionally found near villages and dwellings. The same author states that eight species of owl from Java have been arranged in the museum at the India House ; three eared-owls, and five smooth-headed. —*Eng. Cyc.*

(7918) STROMBIDÆ, a family of Marine Gasteropodous *Mollusca*, belonging to the *Alata* of Lamarck and the *Angyostomata* of De Blainville. In this article the *Strombidæ* will be confined to the genera and sub-genera *Strombus*, *Pteroceras* and *Rostellaria*.

(7919) *Strombus*. There are about 60 recent species of *Strombus* described. Five fossil forms have been described from the Chalk and three from the Miocene beds of the Tertiary.

The species are extremely numerous, and many of them are gigantic in size, the well-known *S. gigas* of the West Indies for example. Like some others of the Turbinated Testaceans, the animals of the genus *Strombus* occasionally produce pearls. Mr. Wood, in his Zoography relates that he saw a pink pearl which was taken from the body of the animal of *S. gigas*, which is fished for the table off the island of Barbadoes. The pearl was discovered by chance while the men were employed in cleaning the fish. Its weight was 24 grains, but it would have been more valuable if it had been round. The same author states that only four of these pearls had been discovered in the vast number of shell-flesh that are annually brought to market in that part of the world, though he has reason to believe that this is in some measure owing to the carelessness of the negroes, who clean their fish without consideration, and have probably in their hurry returned many a pearl to its native element with the refuse of the animal. This pearl was exactly of the same

colour as the interior coat of the shell, and like it in every respect except in figure. Immense quantities of this shell are imported into England from the Bahamas; 300,000 were imported into Liverpool alone in the year 1850. They are used in making cameos, and in the manufacture of porcelain. The species are found in the seas of warm climates; many from those of India, and some from those under and near the equator. They are carnivorous. Species have been found at depths varying from the surface to 13 fathoms.

(7920) *Strombus latissimus* has the shell turbinated, ventricose, smooth on the back, somewhat wrinkled on the wing, brown-orange spotted with white; the spire short and nodulous; the external lip very broad, rounded above, projecting beyond the spire; the anterior margin sharp, but the side of it very thick; the aperture smooth and white, tinged with rose colour. It is found in the East Indian seas.—*Eng. Cyc.*

(7921) *Pteroceras.*—Shell with the wing digitated, and furnished forwards with an elongated canal. There are 10 recent species, inhabitants of the Indian seas, and 100 fossil species, found from the Lias beds up to the Chalk.

(7922) *Pteroceras scorpius.* Shell ovate oblong, gibbous, tuberculate, transversely rugose and knotty, 7-fingered, white spotted with rufous; the fingers rather slender, and knotted at intervals throughout their length; the anterior ones and the tail the longest, and curved; aperture violaceous red wrinkled with white. It is a native of the East Indian seas.—*Eng. Cyc.*

(7923) *Rostellaria.*—Animal imperfectly known, but bearing a considerable resemblance to that of *Murex*, according to Cuvier. The species are found in the Asiatic seas, if we except *Rostellaria Pes Pelecani* and *R. Pes Carbonis* (genus *Aporrhais*), which are found in the Mediterranean and other European seas. A very fine specimen of *Rostellaria rectirostris* was brought up in the mud lying on the fluke of an Indiaman's anchor, in the Straits of Macassar. They are carnivorous. There are 7 recent species, and 70 fossil species. The latter range from the Neocomian beds to the Chalk.

(7924) *Rostellaria curvirostris* (*Strombus fusus*, Linn.) the spindle of collectors, is by far the most common of the Asiatic species.—*Eng. Cyc.*

(7925) STROPHANTHUS. There is a shrub about Amherst that bears a flower resembling the nerium, but with very long linear filiments to the end of each segment of the corolla. It is a species of Strophanthus and well deserving of cultivation.—*Mason.*

(7926) STRUTHIONIDÆ, a natural family of Terrestrial Birds, in which the locomotive energy is thrown into the lower extremities, the wings being in no case adequate to raising the body into the air, and in the majority of instances merely rudimentary. In this respect the genera which compose it are the very reverse of the Humming-Birds, Swallows, Albatrosses, Tropic-Birds, and Man-of-War-Bird; for in the latter the moving-power resides in the highly-developed wings, whilst the feet, especially in the Man-of-War-Bird, are feeble. The *Struthionidæ* consist of the Ostrich, American Ostrich (*Rhea*), Cassowary, Australian Cassowary, or Emu, and that extraordinary bird the Kivi-Kivi, or *Apteryx*, of New Zealand. The anatomy of these animals is referred to in great detail by Professor Owen in his paper on the 'Anatomy of the Apteryx,' in the Transactions of the Zoological Society, London. The most remarkable modifications of the skull in this family occur in the Asiatic Cassowary and the *Apteryx*. In the former the bony crest which is so highly developed in the adult, is hardly perceptible in the young bird, but increases with age, as in the Hornbill and the Guinea Hen [Pavonidæ] —*English Cyclopædia, page* 932.

Mr. G. R. Gray makes the *Struthionidæ* the first family of the order *Cursores*, Temm., the sixth order in Mr. Gray's arrangement, and includes under it the following sub-family and genera:—

Sub-Family 1. *Struthionidæ.*

Genera:—*Struthio*, Linn.; *Casuarius*, Briss.; *Dromaius*, Vieill.; and *Rhea*, Briss.

Sub-Family 2. *Apterygineæ.*

Genus:—*Apteryx*, Shaw.

Sub-Family 3. *Didinæ* (*?*).

Genus:—*Didus*, Linn.

Sub-Family 4. *Otinæ.*

Genera:—*Ctis*, Linn; *Tetrax* Leach; *Sypheotipes*, Less.; *Chlamydotis*, Less.; and *Eupodotis*, Less.

The *Struthionidæ* are placed in Mr. Gray's arrangement between the *Tinamidæ*, the last family of his *Rasores*, and the *Charadriadæ* the first family of his *Grallatores.*

Amongst the *Mammalia* the *Marsupiata* make the nearest approximation to the *Ovipara;* and amongst the birds the *Struthionidæ* approach the Mammals and the Reptiles.

This approximation of Struthious Birds to the *Mammalia* especially cannot fail to strike the physiologist. In the first and typical genus, *Struthio*, it is strongly manifested.

(7927) *Struthio.* Linn. The Ostrich. Joneh, Jaanah and Rinonim of Scripture.

Neamah, also Thar ood-jemmel, Arab.	Struthio camelus, Lat.
Struthio camelos, Ger.	Strazzo, also Struzzulo, It.
Autruche, Fr.	Strausse, Germ.
	Shutr-murgh, Per.

Bill moderate, obtuse, straight, depressed at

the point, which is rounded and unguiculate; mandibles equal and flexible; nasal fossæ longitudinal, prolonged half way down the bill, open. Feet very robust; toes two only, stout and strong, directed forwards, and connected at their base by a strong membrane, the internal toe considerably larger than the external, and furnished with a thick and hoof-like claw, external toe clawless. Wings useless for flight, furnished with long soft undulating plumes, and armed with two spurs, or rather two plumeless shafts, not unlike a porcupine's quill. Head and upper half of the neck scantily covered with a thin down, through which the colour of the skin is visible. There is but one species, the *S. Camelus*.

It would be a needless occupation of space to give a minute description of a bird which is so well known in these days of zoological societies and menageries. The Ostrich is generally understood to be the bird designated by the terms Joneh, or Jaanah, and Rinonim in the Scriptures (Levit, xi. 19; Deut., xiv. 15; Job, xxx. 29; Isai., xiii. 21; xxxiv. 13; xliii. 20; Jer., l. 39; Lament., iv. 3; Mic., i 8; Job, xxxix. 13) In many of these passages, Jer., l. 39, and Isai., for instance, our version reads 'Owls,' and in Levit. does not mention the Ostrich, but the general opinion seems to be in favour of the Ostrich being intended. It is the Neamah of the Arabs, Thar Edjammel (Camel-Bird) of the Orientals, Στρουθοκάμηλος of the Greeks, *Struthiocamelus* of Pliny and the Romans, Struzzo and Struzzolo of the Italians, Strauss of the Germans, Autruche of the French.

The approximation in the digestive organs of the Ostrich to the structure of some of the parts in the *Ruminantia*, especially in the additional ventricle of the bird, is still further strengthened by the bisulcous foot, which may not be inaptly compared to that of the camel, and probably led in no small degree to its appellation of Camel-Bird, to which, moreover, its height, lengthened neck, habit of frequenting the desert, and patience under thirst may have contributed. The food of the ostrich consists of vegetable substances only, but seeds and grain appear to be preferred, and it is consequently a most unwelcome neighbour to the cultivator of the soil, on whose crops the bird commits great devastation. Its iron-eating propensities have long been celebrated, and indeed it picks up and swallows any mineral substance, metallic or not, with indiscriminating voracity. Nor is this propensity confined to the devouring of minerals; for leather, hair, cordage, and wood do not seem to come amiss. In the stomach of one of these birds Valisnieri found a farago of grass, nuts, cords, stones, glass, brass, iron, tin, copper, lead, wood, and among the stones one weighing more than a pound. Perrault took from an ostrich's stomach 70 roubles, the greater part of which were worn down three-fourths of their substance by collision against each other or the pebbles found with them: those which were bent were worn and polished on the convex side, while they remained entire on the concave surface. These copper pieces had tinged everything in the stomach with green. This eagerness for picking up everything, whether or not it can be assimilated or can assist in the grinding down of the food by the action of the stomach, to which no doubt the polishing and wasting of the pieces of money mentioned by Perrault were due, is often fatal to the Ostrich. Too great a quantity of copper or iron thus taken into the stomach has caused the death of the bird. Valisnieri saw one killed by swallowing a quantity of quick-lime; and one kept in the gardens of the Zoological Society of London was first deformed and afterwards died from swallowing part of a parasol. Some of the heterogeneous contents found in the stomachs of these birds are preserved in the Museum of the Royal College of Surgeons. Their speed is great. The swiftest greyhound cannot overtake them; and even the Arab and his horse are obliged to have recourse to cunning as well as speed to close the chase, by throwing a stick dexterously between its legs, or otherwise to disable it. In its flight it spurns the pebbles behind it like shot against the pursuer. Nor is this its only mode of annoyance. Dr. Shaw, who gives a pretty account of the airs which the Ostrich plays off in a domesticated state fanning itself with its expanded wings, and seeming to admire its own shadow, states, that though tame and tractable to those familiar with them, these birds were often very fierce to strangers, especially those of the poorer sort, whom they would try to run down and attack with their feet. They are capable of striking with great force, and the same author gives a melancholy account of a person whose belly was ripped up by a stroke from the pointed and angular claw. The European sportsman, after riding so that the bird shall pass within shot, dismounts and brings it down with the rifle. The strength of the Ostrich is great. Adanson mentions the rapidity with which a large tame one ran, first under the weight of two little blacks, and afterwards under two full-grown negroes, while a smaller bird carried with equal facility one full-grown negro.

The general opinion is that the Ostrich is not polygamous. The number of eggs does not seem to be correctly ascertained. From 20 to 30, and 38 with 13 others scattered around the [illegible] nest—a mere pit in the sand, which is thrown up so as to form an elevated edge round it, about three feet in diameter—have been found together. Some have made the number 80; others reduce it to 10. This is the number that Le Vaillant would assign to a single female, although he disturbed one from the nest containing

the 38 eggs surrounded by the 13 others. This nest he watched, and saw during the day the four females successively sit upon them; and towards the close of the evening a male took his turn of incubation. This then was probably a common nest in which several females had laid their eggs. The passage in Job (xxxix. 14) will occur to every one, and there is no doubt that within the torrid zone the heat of the sun's rays renders the incubation of the female unnecessary, excepting perhaps at night; but in cooler latitudes she performs the maternal office with assiduity, and even in the warmer climates, where an officious determination to sit would in all probability endanger vitality of the eggs, she watches over them; and indeed the hunters have learned from her actions, and doubling back in her flight to one particular spot, where to seek for the nest. If, as has been asserted, the outlaying eggs are intended to serve for the nourishment of the young, it is a proof of provident care for her offspring on the part of the mother.

The flesh of the Ostrich when young is good and palatable, and the eggs are considered a great delicacy. Both Europeans and natives agree in this last opinion. The Hottentot, who abstracts the egg from the nest with a long stick, that the hen may not take alarm at the human touch, and not abandon the nest, but go on laying, as the common hen will do to a great extent when her nest is robbed, buries them in hot ashes. They are said to be excellent when eaten with a sufficient quantity of butter. The brains of hundreds of these birds not unfrequently made a dish at the insane Roman suppers; and Firmus is said to have eaten a whole ostrich at a meal. The flesh of the bird was prohibited by the Mosaical law as unclean, and the Arabs regard it in the same light; but many of the barbarous tribes in the interior of Africa feed on it without scruple. The well known plumes form a material article of commerce for the head-dress of European ladies, &c. There is in the noble and admirably arranged zoological gallery of the British Museum a fine and well-preserved series of young ostriches. Not the slightest trace of a nail is observable on the external toe of any of them, any more than on that of the adult bird. The usual height of the ostrich is from 7 to 8 feet, but it has reached 11 feet. The ostrich is a native of Africa and is scarcely known beyond the limits of the Arabian deserts.

(7928) *Casuarius* (Briss.)—Bill straight, carinated above, rounded and bent at the point; upper mandible slightly vaulted; the edges depressed, and notched or jagged towards the extremity; the lower mandible rather angular below towards the point; nasal fossæ nearly as long as the bill. Head helmeted. Front of the neck naked, and furnished with two wattles. Toes three. Wings entirely unfit for flight, furnished with five rounded naked pointed quills.

(7929) *Casuarius Emeu* has the bill compressed laterally, the head surmounted with a bony prominence covered with a horny substance; skin of the head and the upper part of the neck naked, tinged with cærulean blue and flame colour, with pendent wattles like those of a turkey-cock; wings furnished with some stiff featherless quills; nail of the internal toe much the strongest. "It is," says Cuvier in continuation, "the largest of the birds after the ostrich, from which it differs sufficiently in its anatomy, for it has short intestines and small cæca, wants the intermediate stomach between the crop and the gizzard, and its cloaca does not exceed that of other birds in proportion. This well-known bird was named Emeu by the early Portuguese navigators. It is the *Emeu* vulgo *Casoaris* (the latter appearing to be the Malayan appellation) of Bontius, the *Struthia Casuarius* of Linnæus, *Casuarius galeatus* of Vieillot, and Cassowary of the British naturalists, who now apply the term Emeu to the Australian Cassowary (*Dromaius*, Vieill.). Its height when erect is about 5 feet. It is a native of the peninsula of Malacca and the great chain of islands to the south and east. Bontius notes it from Ceram and the other neighbouring Molucca Islands. M. Lesson observes that it is very common in the islands of the Asiatic Archipelago, and especially at New Guinea. It is frequently seen alive in English menageries, and is common in museums. The species, which is characterised by M. Lesson as "stupid and massive," feeds on seeds and herbage according to him; but Cuvier says that it eats fruits and eggs, but no grain. Bontius states that he does not think it should be placed among the birds: "Alæ enim ad currendum pro velo, non ad volandum inserviunt." He adds, that when irritated, it does not rush forward to the attack, but turns itself obliquely, kicking backwards at the enemy. Cuvier observes that the featherless quills serve the bird for offensive weapons. Bontius remarks that the eggs are very different from those of the Ostrich, by reason of their thinness and colour, for their shell is greenish, ornamented with numerous tubercles of a deeper green (saturé viridibus): he adds that they are eaten by the natives. Cuvier relates that the bird lays a small number of green eggs, which it abandons, like the Ostrich, to the heat of the climate.—*Eng. Cyc.*

(7930) STRYCHNOS (from στρύχνος), a name applied by Theophrastus and Dioscorides to a kind of Nightshade, and adopted by Linnæus for a genus of Plants belonging to the natural order *Apocynaceæ*. This genus has been made the type of a distinct order by Blume, who has been followed by Link, D. Don, and others. The principal difference that it presents from the order *Apocynaceæ*, to which it is referred by Von Martius, Brown, and Lindley, is in its peltate seeds and simple succulent fruit. This genus is com-

posed of trees or shrubs, which do not yield a milky juice, and have opposite usually nerved leaves and corymbose flowers. Some of the species are possessd of tendrils, and are climbing plants. The calyx is 5-parted; corolla tubular, funnel-shaped, with a 5-parted spreading limb, which is valvate in æstivation: the stamens are 5, inserted into the throat of the corolla; ovary 2-celled, with a single style and capitate stigma; fruit a berry, pulpy inside, with a hard rind; seeds peltate, numerous, attached to a central placenta, with copious albumen, and foliaceous embryo. The species are not numerous, and are found principally in the tropical parts of Asia and America. One has been described by Mr. Brown a native of Australia.—*Eng. Cyc.*

(7931) STRYCHNOS COLUBRINA. Malabar and Ceylon.

Modira canoram, RHEEDE. | Naga musada, TEL.

The wood (lignum colubrinum), Pao de Cobra. A climber with stem of great size, often from 8 to 12 inches in diameter, wood hard, intensely bitter, and of light grey colour. The wood of this plant is the true Pao de Cobra of the Portuguese. That of the root is deemed a powerful remedy for the bite of the cobra capella. Several woods have however received the appellation of *Bois de couleurre*, (Lignum colubrinum) in different countries, viz. the Ophyoxylum serpentinum in Amboyna, the Ophiorhiza mungos in Java, Polygala senega in North America, &c. all for their supposed virtues as antidotes to snake poison. A very large proportionate quantity of strychnine exists in the wood of this root.—*O'Shaughnessy, page* 442.

Strychnos Colubrina, Snake-Wood, or Snake-Poison-Nut Tree, is a climbing plant with simple tendrils; leaves oblong or oval, obtuse, 3-nerved, shining; ovaries many-seeded. It is a native of the coast of Coromandel and of Silhet. It has small greenish-yellow flowers, and fruit as large as an orange, of a yellowish colour. It is called by the Telingas Naga Mussadi, and is considered by the Indian doctors as an effectual remedy for the bite of the Naga, or Cobra di Capella, the well-known poisonous snake; for this purpose it is used both externally and internally. It should however be stated as the result of the observation of the most intelligent travellers, that these vegetable remedies are not to be depended on in cases of bites of serpents, and that where danger is apprehended the only effectual remedy is excising the wound. The wood of this and other species of the genus is brought to Britain, and is known under the name *Lignum colubrinum.—Eng. Cyc.*

(7932) STRYCHNOS IGNATII, St. Ignatius's Bean, has ovate acute glabrous leaves; pyriform fruit with many seeds, and 4-flowered axillary peduncles. It is a climbing shrub, without tendrils, bearing long drooping white flowers, which have the scent of jasmine. This species is the *Ignatia amara* of Linnæus, but has been referred to the present genus by later botanists. It is a native of Cochin-China, the Philippine Islands, and other parts of Asia. This plant is called Papeeta in India, and is used by the native doctors as a remedy in cholera, but is administered in conjunction with Jehiree (*Cocos Maldivica*). When given in over doses the symptoms are those of poisoning by strychnia, as vertigo, convulsions, &c. and the remedy used for these effects is lemonade in large quantities, which is said to afford relief speedily.—*Eng. Cyc.* See S. SANCTO IGNATI.

(7933) STRYCHNOS LIGUSTRINA. Cajualar, Caju-nassi, Cajubadaira pail or laut. Malayan archipelago. A tree resembling the orange tree; berries globose, yellowish green, two to eight seeded. This yields the *Lignum colubrinum* of Timor, used for the objects already described.—*O'Shaughnessy, page* 443.

(7934) STRYCHNOS NUX VOMICA.

Mooshtee, TEL.	Moottee, TAM.
Kachla, HIND.	Kha-Boung, BURM.
Yettie cotay, TAM.	Koochila, BENG. DUK. HIND.
Musada, TEL.	
Culaka, Cutaka, also Vesha-moosti beejum, SANS.	Koodaka dornatta, CING.
	Khanek ul Kalb, ARAB.

A moderate sized tree, with a short crooked trunk. Branches irregular, the young ones long and flexuose, with smooth dark-grey bark. Wood white, close-grained, and bitter. Leaves opposite, with short petioles, oval, smooth, and shining, 3 to 5-nerved, differing in size. Flowers small, greenish-white, in terminal corymbs. Calyx 5-toothed. Corol funnel-shaped; limb 5-cleft, valvate. Stamens 5; filaments short, inserted over the bottom of the divisions of the calyx; anthers oblong, half exserted. Ovary 2-celled, with many ovules in each cell, attached to the thickened centre of the partition. Style equal to the corol in length. Stigma capitate. Berry round, smooth, about the size of an orange, covered with a smooth somewhat hard fragile shell, of a rich orange-colour when ripe, filled with a soft white gelatinous pulp, in which are immersed the seeds attached to a central placenta. Seeds peltate or shield-like, slightly hollowed on one side, convex on the other, about ¾ of an inch in diameter, and about two lines in thickness, thickly covered with silky ash-coloured hairs attached to a fibrous testa, which envelopes the kernel composed of horny bitter albumen, of the form of the seed and of the embryo imbedded in a hollow in its circumference.—Roxb. Corom. i. t. 4.—A native of the Indian Archipelago and of the forests of the Peninsula of India, as well as of the Southern parts of the Bengal Presidency, as near Midnapore.—Esenb and Eberm. 209. St. and Ch. 11. 52.—*Royle.*

All parts of the plant, except the pulp and flowers, are exceedingly bitter especially the wood of the root, and the inner layers of the bark.—*Roxb. Fl. Ind. i.* 475. The seed is inodorous, but its taste insupportably acrid and bitter. It is very difficult to reduce the seeds to powder; they must be first rasped, the raspings steeped in mucilage, then dried and powdered; or what is preferable, the rasping should be exposed to the steam of water for an hour, and then stove-dried, and powdered in a covered mortar. The *bark* is of an ash-grey colour while young, thin, compressed, inner surface black, outer surface of the larger pieces spotted with red rust-like patches. Fracture brittle, taste intensely bitter; nitric acid gives a blood-red stain to the black parts, and changes the red to a rich grass green. This bark is known to the European druggists under the name of the "*false angustura.*" Its nature was long suspected, but first clearly ascertained by Dr. O'Shaughnessy, (see the Journal of the Medical and Physical Society of Calcutta, Jan. 1837). The same bark is commonly sold in Calcutta, under the name of "*Rohun,*" and substituted for the harmless bark of the *Soymida febrifuga.*—*O' Shaughnessy, p.* 437.

Strychnos nux Nomica. Grows in the hilly parts of the Concans; where the nuts are used for poisoning fish.—*Riddell.* It is very common on the rocky sides of the hill at the back of Maulmain. The reputed property of the wood to cure the bite of venomous snakes, as stated by Lindley, is never heard of there, and is doubtless quite apocryphal.—*Mason.*

Strychnos nux-vomica is a very common tree throughout the Pegu Forests. The timber is strong and close-grained, but never of very large size. Wood, white colored, adapted for fancy work and cabinet making.—*McClelland.* Dr. Pereira thinks that the *Nux Mechil* of Serapion is Nux Vomica; but in Persian works this name is applied to a Datura. The wood of the Nux Vomica tree is said by Dr. Christison to be often substituted for the *Lignum Colubrinum,* or Snake-wood.—*Royle.* See NUX VOMICA.

(7935) STRYCHNOS POTATORUM. Lin.

Clearing nut, ENG.	Tsillaghenzaloo, TEL.

Clearing nut tree ENG.	Chillbeeng or neermul or neermulee, HIND.
Chilla ginja, TEL.	
Taitan, TAM.	Induga or Titan cotta BENG.

A large tree found among the mountains of Bengal, flowers during the hot season, occurs in gardens in many parts of India. The wood is hard and durable, pulp when ripe eaten by the natives. The ripe seeds are sold in the bazars for clearing water. The entire plant is destitute of the poisonous ingredients of the other species. By rubbing the nuts round the inside of water-pots, the impurities very soon fall to the bottom. This effect is so generally known that the seeds are usually carried by travellers in India. The nature of the action has not been clearly ascertained. It probably depends on astringency in the fruit. Ainslie informs us that the ripe fruit is deemed emetic by the Tamools of Southern India, when given in powder to the quantity of about half a tea spoonful—*O' Shaughnessy, page* 443. On this point, Ainslie, says, this fruit though, when very young, it is made into a preserve and eaten, is reckoned in its ripe state amongst the emetics of the Tamool Practitioners. The seeds are used for the purpose of clearing muddy water. One of them being usually rubbed hard for a short time round the inside of an earthern pot, the water is afterwards poured into it and left to settle: the impurities soon subsiding the water will be found clear and tasteless. The Canarese name of the tree is chittu.—*Ains. Mat. Med. p.* 119. Dr. Hooker found the *Strychnos potatorum,* forming a dense foliaged tree, 30 to 60 feet high, and while some individuals are a pale yellow, others are deep green, yet both in apparent health.—*Hooker Him. Jour. p.* 50.

Strychnos Potatorum, the Clearing-Nut, has ovate or oval glabrous pointed leaves; a deeply-fissured bark; and berries containing only one seed. It is an abundant plant in the woods and mountains of the East Indies. It has shining fruit, which is black when ripe. When full grown it attains a height of from 15 to 20 feet, and, has a very hard wood, which is used for various economical purposes. The English name is derived from the use which is made of the seeds, which, when dried, are sold by the natives for the purposes of clearing muddy water.—*Eng. Cyc.*

(7936) STRYCHNOS SANCTI IGNATII. ST. IGNATIUS' BEAN. *Syn.* Ignatia amara.

Papeeta. HIND.

A branching tree, a native of the Philippine islands. The seeds are an inch long, (the size of a large olive.) According to the analysis of Pelletier and Caventou, these beans contain igasurate (strychnate) of strychnia, wax, concrete oil, yellow colouring matter, green starch, bassorine, and vegetable fibre. The strychnine is present in three times the quantity of that in the kuchila nuts, but there is no brucine. Its activity is consequently very great, its uses the same as those of nux vomica. Besides the symptoms therein described the papeeta nut purges in small doses, and is hence deemed, and

we believe correctly, to be an efficacious vermifuge medicine.—*O'Shaughnessy, page* 441. See S. IGNATII.

(7937) STRYCHNOS TIEUTE. (TSHELLIK OR TJETTIK.) A native of Java, a large climbing shrub; an exceedingly violent poison, which acts exactly in the same manner as strychnine, is prepared from the bark of the root of this tree. The root is called Upas Radja, but does not belong to the true Upas tree of Java, which is the Antiaris toxicaria of the Mat. Med. Order Urticaceæ.—*O'Shaughnessy, page* 444.

The *Strychnos Tieute*, Tjettek, or Upas Tieute, has elliptical, acuminate, 3-nerved, glabrous leaves, and simple tendrils, which are thickened opposite the solitary leaves. This plant is a climbing shrub, and is a native of Java and is said to be the true Upas-Tree of that country. It is undoubtedly the most poisonous species of the genus, and yields the greatest quantity of strychnia. There are several other plants which are called by the name of Upas in various parts of Asia. The natives of Java prepare from this species one of the most deadly of the various poisons that are used by barbarous nations for producing death by the wounds occasioned by their arrows.—*Eng. Cyc.*

(7938) STRYCHNOS TOXIFERA. A native of Guiana, ascertained to be the basis of the celebrated Woorara poison.—*O'Shaughnessy, page* 443.

(7939) STUCCO. A compound of paris-plaster and lime, used in making cornices, &c.

(7940) STURIONIDÆ, a family of Fishes belonging to the section, *Chondropterygii*, the species of which are distinguished from others of the section by the gills being free, as in ordinary fishes, thus differing from the second great division of the fishes having a cartilaginous skeleton, such as the Sharks and Rays, in which the gills are fixed, and have their outer margin attached to the skin. The *Sturionidæ*, or Sturgeon Tribe, have moreover but one opening to the gills, and this is protected by an operculum. Four genera are contained in this family, *Accipenser, Spatularia, Chimæra*, and *Collorhynchus*. To the first of these genera belongs the common Sturgeon (*Accipenser Sturio*, Linn.), which is not unfrequently met with in mouths of English rivers. It is of an elongated form, and has the body protected by numerous indurated plates, which are arranged in a longitudinal series; the head is entirely covered by bony plates; the muzzle is elongated, and more or less pointed; and the mouth, which is placed on the under side of the head, is tubular, and destitute of teeth: on the back is a single dorsal fin, which is placed on the hinder third of the fish: the tail is forked, and the upper lobe is the largest, as in the Sharks.—*Eng. Cyc.*

(7941) STYLIDIUM (a diminution of 'stylus,' column), the name of a genus of Plants, of the type of the natural order *Stylideaceæ*. This is chiefly an Australian genus of plants, and is remarkable for its gynandrous structure, and for the irritability of the column formed by the union of filaments and style. The species of this genus described by Mr. Brown, in his 'Prodromus Floræ Novæ Hollandiæ,' are forty-five in number; besides these there are two or three natives of the East Indies.—*Eng. Cyc.*

(7942) STYLOCERUS RATNA. The Barking Deer, occurs at Siligoree, in the Terai.—*Hook. Him. Jour. p.* 399,

(7943) STURNIDÆ, Mr. Vigors' name for the Starling Family, belonging to his order *Insessores*. Linnæus placed his genus *Sturnus*, consisting of only five species, among which the Water-Ouzel appears as *Sturnus Cinclus*, between *Alauda* and *Turdus*, in his order *Passeres*. Cuvier arranges the Starlings between the Cassiques (*Cassicus*) and the Crows (*Corvus*).

(7944) STURNUS VULGARIS, the Common Starling, the Stare. This bird is well known in Great Britain as one of the handsomest of British birds, and is a general favourite. It is intelligent, sprightly, has a retentive memory, and, when kept in confinement, the males learn to whistle tunes and imitate some of the sounds of the human voice. They are social, living in flocks throughout the greater portion of the year. The Starling builds in church steeples, under caves, and in holes of houses, towers, or ruins. The nest is made of slender twigs. The eggs are four or five in number, of a delicate pale blue, 1 inch 2 lines in length by 10 lines in breadth. Their food consists of worms, insects, and snails. They are frequently seen in meadows searching for food amongst cattle and sheep. They sometimes eat berries and grain. They occasionally congregate together in prodigious numbers in shrubberies and plantations. The Starling is common in almost every part of the United Kingdom. It is found in the north of Europe, and as far east as Nepaul, the Himalaya Mountains, Calcutta, China, and Japan. It has been seen in Africa as far south as the Cape of Good Hope.

(7945) *Pastor roseus*, the Rose-Coloured Ouzel. This bird is an accidental visitor in the British Islands. Like the Common Starling, it has a wide geographical range. It is very numerous in various parts of Hindustan. It inhabits Syria, Egypt, and Africa. It flies in flocks, and has many of the habits of the Common Starling. The adult male has a beak of a yellowish rose-colour; the head, neck, wings, and tail black, glossed with violet-blue; the feathers on the head elongated so as to form a flowing crest; the back, scapulars, and rump of a delicate rose-

colour; the chin, throat, and front of the neck, black; breast, sides, and abdomen, like the back, of rose colour; thighs and under tail-coverts black; legs and toes yellowish-brown; claws darker brown. (Yarrell.)—*Eng. Cyc.*

(7946) STYRACEÆ, *Storaxworts*, a small natural order of Plants, placed by Lindley in his Polycarpous group of Monopetalous Exogens. The species are trees or shrubs, with alternate leaves without stipules, usually turning yellow in drying. The flowers are axillary, and are either solitary or clustered with membranaceous bracts. The calyx is persistant, and has five divisions frequently differing from the calyx and with imbricated æstivation; stamens varying in number, arising from the tube of the corolla, with 2-celled anthers; ovary 3-5-celled, with few ovules, a simple style, and capitate stigma; fruit a drupe; seeds solitary, with the embryo lying in the midst of albumen. This order is nearly allied to *Ericaceæ* from which it differs in habit, its definite seeds, and its frequently inferior ovary. It differs from *Ebenaceæ* in its stamens being perigynous, in the insertion of the ovules, and its simple style. It is however an order on which there are many different opinions, some referring all its genera to *Ebenaceæ*, whilst others separate from it the genera *Symplocos* and *Halesia* as types of distinct orders. The species are found in the temperate and tropical parts of North and South America, and also in Nepaul and China. This order is chiefly remarkable, in an economical point of view, for furnishing the Storax and Benzoin of commerce, which contain a peculiar acid called the Benzoic Acid. Some of the species are used for dyeing yellow, and a species of *Alstonia* is employed as a substitute for tea. The various species of *Halesia* are the Snow-Drop Trees of the Carolinas. —*Eng. Cyc.*

(7947) STYRAX, Linn. *Decand. Monog.* Calyx rather campanulate, nearly entire, or 5-toothed. Corolla campanulate at the base, deeply 5—7 cleft. Stamens 6—16, seldom 10, exserted; filaments united to the tube of the corol, sometimes adhering at the base into a ring; anthers linear, 2-celled, opening by internal longitudinal slits. Ovary inferior, Style simple. Stigma obtuse, somewhat lobed. Drupe dry, splitting imperfectly into 2 or 3 valves, with 1—2—3 stones. Seed solitary, erect, with a large, leafy, thin embryo lying in the midst of fleshy albumen, with an inferior radicle (*Lindley.*)—Styrax officinale and S. Benzoin yield officinal products. —*Royle.*

(7948) STYRAX BENZOIN, Benjamin, Storax, or Gum-Benjamin Tree. Leaves ovate oblong, pointed, glabrous above, downy beneath; racemes compound, almost the length of the leaves. It is a native of Sumatra and Java. It is the plant which produces the Benzoin, or Gum Benjamin, of commerce; and which, as well as Storax, is used in medicine. [BENZOIN.] The great consumption however of these resins is not as medicines, but in their use as incense in the worship of the Roman Catholics and Mohammedans. Though older botanists, as Garcias, Grim, and others, were acquainted with the tree that yielded Benzoin, Ray confounded it with the genus *Laurus*, and Linnæus with the genera *Croton* and *Terminalia*. Dryander gave a correct account of the plant in 1787, and referred it to its present position.—*Eng. Cyc.*

(7949) STYRAX OFFICINALE. L. E. D. Balsamum, L. Resina, E. Balsamic exudation, E. of Styrax officinale, Linn. Officinal Storax. A small tree with smooth bark, and downy spots and petioles. Leaves ovate-obtuse, of a green colour, and shining above, white and downy on the under-surface, something like those of the Quince tree. Flowers white, in terminal racemes of a few flowers, which resemble those of the orange. Calyx downy (2), cup-shaped, 5 to 7 toothed. Corolla externally hairy, with 5 to 7 segments. Stamens (2) 10 to 16. Fruit about the size of a cherry, coriaceous, downy, with 1 or 2 nuclei. —A native of Asia Minor and Syria common in Greece, and cultivated in the south of Europe. As this plant does not yield a balsamic exudation in all these situations some Storax has been thought to be yielded by *Liquidambar orientale*. Du Hamel, however, states having seen it flow from a tree near the Chartreuse of Montriau.—Ehenb. and Eberm. 210. Fl. Græc. t 375. St. and Ch. 47. Storax (στυραξ) was well known to the Greeks. Dioscorides compares the tree producing it with the Quince tree. It is called *asteruk* in the East. Much of the Storax of commerce is yielded by this tree when incisions are made into it. The tree is common in Asia Minor where Professor Forbes was informed Storax was collected from it. Several kinds are known in commerce and described in books. (*v.* Pereira.) Of these, Storax in grains, Reed Storax (Storax calamita), called Storax amygdaloides by Guibourt, used to be most common. One kind of Liquid Storax is yielded in the islands of Cos and Rhodes by *Styrax officinale*, which is there called βουχουρι. This seems only the Arabic word *Bukhoor*, signifying incense or fumigation, put into Greek letters. Common Storax is in brown or reddish-brown masses, varying in shape (in turf-like cakes, *c.*), light and friable, but possessing some tenacity, softening when warmed. It has a fragrant balsamic odour, and a warm aromatic taste. It consists evidently of saw-dust united with some balsamic substance. Merat and De Lens inform us that a factitious compound is made both in the Levant and at Marseilles with the saw-dust of the wood and the juice of this tree, with a little Benzoin. The ancients also employed saw-dust, honey, wax, iris-root, &c. Storax, when exposed to air, becomes covered with an efflorescence of Benzoic Acid.

It burns with a white flame, leaving a carbonaceous residue; gives a slight colour and odour to water; but the greater part, with the exception of impurities, is dissolved by Rectified Spirit. Reinsch gives as the constituents of the Red Storax, a trace of Volatile Oil, Benzoic acid 1 to 2-6 per cent., Gum and Extractive 7-9 to 14, Resin 32·7 to 53·7, with much woody fibre. It hence requires to be purified.—*Royle. p* 471. *Storax*, then, Ustrouk Hind., occurs in three different forms—1. in grains; 2. in soft masses; 3. in brittle masses.

1. *Storax in grains*, the rarest and purest of all, in transparent, yellowish-white or reddish-yellow grains, the size of a small bean, the consistence of wax, and capable of consolidating into a thick mass. Odour strong, penetrating, and very agreeable. Taste aromatic and bitter.

2. *Storax in soft mass*, or amygdaloid storax (*Storax calamite*, Lemery), softer than the preceding species, easily fusible, with brown fracture, displaying almond-like yellowish tears. Odour very sweet, like benzoin, taste sweet and perfumed.

3. *Massive hard storax*. Light brown, yellow, reddish brown and friable, sometimes slightly tenacious, softens under the teeth. Odour less than that of two preceding varieties, and resembling balsam of Tolu; flavour sweet. This variety is very impure, being usually adulterated with saw-dust, &c. The better kinds of storax burn with a white flame, and give a light, spongy, carbonaceous residue. It communicates to water a yellow colour and fragrant smell. It is soluble (except the impurities) in alcohol and ether. Storax is brought to Europe from Turkey in Asia; formerly it was packed in bulrushes, at present it is sent in bladders. M. Fee deems the origin of this drug uncertain; the styrax tree, cultivated in the south of Europe, affords no balsam, but this may be because the soil and climate differ from those of its native country. The strong resemblance between this product and the balsam copalm produced by the Liquidambar styraciflua, led to the idea that storax might probably be secreted by some congenerous tree, and Bernard de Jussieu pointed out the Liquidambar orientale, a tree common in Syria, as the most likely source of the article. It is now, however ascertained that storax is in reality produced by the Styrax officinale, a native of the Levant, Syria, Palestine, Greece, and the Peloponesus. Storax or styrax, (Greek στυραξ, Arabic *estorak*,) is a word of unknown origin.—*O'Shaughnessy page* 429-30.

(7950) SUÆDA. Of this genus Wight, in Icones, gives Sueda Indica, 1796; monoica, 1792.

(7951) SUÆDA INDICA.

Koyey Passeeray keeray, Tam.

A procumbent weed with pea green leaves, found in salt marshes, sometimes in gardens, used in native culinary as spinach.—*Jaffrey.*

(7952) SUBZEE OR SUBJA. An intoxicating liquor prepared from hemp leaves; black pepper cardamoms; Poppy seed: cucumis utilissimus and sativus. It exhilirates without injurious consequences.—*Herklots.*

(7953) SUCCORY. Cichorium Intybus. Much used in France as a winter salad under the name of *Barbe du Capucine*. The common way to grow this plant is similar to carrots. When the tapering roots have attained some size, they are lifted, the leaves cut off, the roots are then planted in sand in a dark room or cellar; where in consequence of the absence of light the roots throw out white leaves which make an excellent vegetable. This plant is the Cichory of commerce used in the adulteration of Coffee.—*Jaffrey.*

(7954) SUFURA KOOMRA. *Hind.* Suppara Koomrog, *Duk.* Cucurbitis Ovifera. Vegetable Marrow.

(7955) SUGAR.

Sukkur, Arab.	Shakur, Pers.
Suiker, Dut.	Acucar, Port.
Sucre, Fr.	Sachar, Rus.
Zucker, Ger.	Sarkara, Sans.
Shuckar, Guz Hind.	Azucar, Sp.
Zucchero, It.	Sakkara, Tam.

The commercial Sugars of Asia are chiefly the products of the

Sugar-cane, Saccharum officinarum.
Do. do. do. sinense.
Date Sugar, Phœnix sylvestris.
Palmyra Sugar, Borassus flabelliformis.
Cocoanut Sugar, Cocos nucifera.
Ejoo or Gomuti Sugar, (Saguerus Rumphii,)
Arenga saccharifera.
Nepal Sugar, Nipa fruticans.

The great commercial importance of this product would require that it were treated in a large volume, and to keep an intelligible notice of it within the scope of this work may be an impossible task.

Sugar exist in all vegetables having a sweet taste, but is chiefly procured from boiling the expressed juice of the sugar cane, a plant which thrives from the equator to the 32° of latitude. In commerce, Sugar is met with in different degrees of purity, from *common brown*, to *double refined* and *crystalized*; each quality being generally characterised by a distinctive appellation. Sugar of various quality, is largely manufactured in the Bengal, Madras, and Bombay Presidencies, from the Sugar-cane. A large quantity of the sugar made in India is exported to the Arabian and Persian Gulfs, London, &c. China and Siam sugar is largely imported intoBombay, a good deal of which is re-exported to the above named ports.—*Faulkner.*

History—Coeval with the use of other vegetable products, for domestic purposes in India, appears to have been the employment of the juice of the sugarcane; though it would not seem that the ancients possessed any knowledge of the process by which this saccharine matter is converted into a crystallized substance. Every mention made of it, from the various passages in Scripture down to the commencement of the Christian era, is simply that of a "sweet cane," or of a "fine kind of honey found in an Indian reed." Nearchus, the admiral of Alexander the Great, was the first who made known the existence of the sugar-cane, in the western world; and from his time we find frequent allusion to this vegetable product, by Theophrastus, Varro, Dioscorides, and others. Herodotus alludes to "honey made by the hands of men;" but enters into no details. Lucan speaks of the sweet juice expressed from reeds, which the people of India were fond of drinking, and which Pliny calls "saccharine." Still later, Arrian, in his *Periplus of the Red Sea* alludes to the honey from reeds called sacchar, as an article of trade between the Indian ports and the countries of the Red Sea. The sugar-cane was found growing in the meadows about Tripoli in Syria; and mention is made by a writer of that day of eleven camels loaded with sugar being taken by the Crusaders. Marco Polo, who travelled in the East in the year 1250, found abundance of sugar produced in the province of Bengal; and from the almost universal growth of the cane in that presidency at the first occupation of the country by the British, there is good reason for believing that its culture had rapidly extended at a very early period. From the earliest European intercourse with India, sugar in a great variety of forms was met with in daily use. No Hindoo lives without it, either as sugar, in its natural state, or in cakes called "jaggery." Upon the first possession of Calcutta by the Company there was a flourishing export trade in sugar to the Indian coasts, some of the Eastern islands, and a few ports in Arabia and Persia, to the extent of about 1500 tons; whilst the local consumption of the article was enormous. The quality of this sugar was, however, very inferior; and about the year 1776 some attempts were made to introduce into India the Jamaica mode of growing the cane, and manufacturing the sugar; but at that time these efforts were not attended with any success. The culture of the cane was nevertheless greatly extended; and by the year 1792, when the British duties on tea were reduced, and a consequent increased demand for sugar arose, not only in England but in many parts of Europe, so as greatly to enhance its price, the Company made large shipments of the article home; although all endeavours to get it rated for duty on the same scale as that from the West Indies failed. The price realised in the English market for Company's sugars was at this time 88*s.* 6*d.*; but it rose gradually until it reached 156*s.* per hundred-weight: a figure which, in spite of discriminating duties and high freights, left to the importers a clear profit of eighty or ninety per cent. The first agitation against the slave-trade and slave grown produce helped to bring East-India sugars into more favourable notice; and the result of this growing demand, met by increasing culture in Bengal, was, that from 100 or 200 tons shipped home in 1790, the imports into London from Bengal in 1805 and 1807 amounted to 5000 tons. The following were the exports of Bengal sugar to Great Britain between the years 1803 and 1810:

Years.	Cwts.	Value.	Years.	Cwts.	Value.
1803	27 808	£56 789	1807	105,755	199,873
1804	78,619	208,060	1808	48,499	88,016
1805	102,732	295,814	1809	33,617	68,750
1806	67,455	150,250	1810	43,236	101,040

From this time forward the sugar trade with British India steadily increased; the throwing open of the Indian ports to private ships; the final cession of the Company's trade; the reduction of the Imperial duties on Sugar, the produce of the British possessions in the East; the failure of all the West Indian plantations, aided by the growing demand for sugars of all kinds, were all causes that had a sensible influence in bringing this branch of commerce to a degree of importance which fifty years since, could not have been anticipated by the most sanguine. In 1844 the imports of Bengal and Madras sugars into the port of London alone, amounted to 31,000 tons: in 1845, to 44,000 tons, in 1851 to 80,294 tons, of which $\frac{2}{3}$ were from Bengal and $\frac{1}{3}$ from Madras. The general import of sugar from the East Indies was as follows.

	1849	1850	1851	1852	1853
	Cwt.	Cwt.	Cwt.	Cwt.	Cwt.
Refined,.....	56,074	12,474	31.407	2,565	15,464
Unrefined, ...	1,471,139	1,362,837	1,574,478	1,302,150	1,225,273
Total, ...	1,527,213	1,375,311	1,605,884	1,304,721	1,240,737

Capper's Three Presidencies.

In addition to the Sugar-cane, however, as was noticed at the commencement of this article, this product is now obtained from several other sources, which will be noticed as we proceed. Of the palm tribe, as producing Sugar, it may be here mentioned that the fermented toddy from the Gomuti palm, the *Arenga saccharifera*, is boiled to a syrup, and thrown to cool in small vessels, the form of which it takes, and in this shape it is sold in the markets.

Upwards of four thousand years ago, the Hindoos knew how to make sugar from the flowers of the Madhuca (*Bassia latifolia*, Roxb.) but there is reason to suppose that sugar was

made from some of the palms, at a much earlier period. At Jaffna in Ceylon, the sweet unfermented toddy, of several palms, is boiled until it becomes a thick syrup, when a small quantity of scraped cocoanut is thrown in, to ascertain, by the feel, whether the syrup has attained the proper consistency: if that be the case, it is poured into small baskets of palmyra leaf, in which it cools and hardens into jaggery. In the year ending 5th January 1850, Ceylon exported 9,580 cwts., of jaggery, bearing a customs value of £1,937, fully two thirds of which consisted of the produce of the palmyra. To make *Vellum*, or crystallised jaggery, the syrup is not boiled for so long a time, the pot which contains it, is covered, and put aside for some months, at the end of which period the crystals are found in abundance. The juice of the palmyra possesses a greater quantity of saccharine matter than most of the other palms; about three quarts of it suffice for boiling into one pound of jaggery. The chief fault of the jaggery made at Jaffna, seems to arise from the excessive application of lime, a small quantity of which is of course absolutely necessary to prevent fermentation. It is said that sugar which is chiefly the produce of the jaggery, is more granulated and higher prized than that obtained from the sugar-cane. Large quantities are imported into Europe or Cuddalore and Madras. The Export of Sugar from Ceylon for Madras is about nine thousand tons annually and a considerable portion of that is supposed to be the produce of the Palmyra.

Cocoanut tree.—In Ceylon when the toddy of the cocoanut tree is to be converted into sugar, particular care is taken to employ only clean and well dried vessels, which are regularly changed. Eight gallons of sweet toddy, boiled over a slow fire, yield two gallons of a very luscious fluid, called Penni, or honey, or Jaggery, or sugar water; which quantity being again boiled, yields a kind of coarse brown sugar, known as jaggery, which is formed into round cakes. When prepared for domestic purposes, each cake is separately tied up in pieces of dried banana leaves and suspended in a smoky place.

Phœnix dactylifera. Sugar.—Every twelve pints of its toddy boils down to one of *Jaggery* or *goor*, and four pounds of jaggery yield one of good brown sugar, so that the average produce of each tree is about seven or eight pounds of sugar annually. In the whole province of Bengal, about 15,000 maunds or 1,000,000 hundredweight of sugar is manufactured from this Date tree annually, but it sells at about one-fourth the price of that of Sugar cane.

The sugar made from the juice of the Kittul tree, the *Caryota urens*, is considered to possess more saccharine properties than that produced from the cocoanut tree.—*Cupper.*

Sugar is obtained from many grasses. It is procured in Italy from *Sorghum saccharatum*; in China, from *Saccharum sinense*; in Brazil, from *Gynerium saccharoides*; in the West Indies, from *saccharum violaceum*; and in many other parts of the world from *S. officinarum.* The last two are commonly known as sugar canes, and they are generally considered as varieties of a single species of the *S. officinarum*, which is now widely spread over different parts of the world. Some curious specimens of palm sugars were exhibited at the Great Exhibition of 1851, among others,—gomuti palm sugar (*Arenga saccharifera*) from Java; date palm sugar, from the Deccan; Nipa sugar, from the stems of *Nipa fruticans*, as also from the *Bassia latifolia*,—an East Indian tree. Among the other sugars shown were beet-root sugar, maple sugar, date sugar, from Dacca, sugar from the butter tree (*Bassia butyracea*), produced in the division of Rohelkund; sugar candy, crystallized by the natives of Calcutta and other parts of India. Sugar and molasses from the grape, were also shown from Spain, Tunis and the Zollverein. An experienced sugar-dealer easily judges of the value of sugar by the taste, smell, specific gravity, moisture and general appearance. The value of molasses may be determined by drying at 220 degs., and by the taste.

The commercial demand for sugar is nevertheless mainly supplied from the juice of the cane, which contains it in greater quantity and purity than any other plant, and offers the greatest facilities for its extraction. Although sugar, identical in its character, exists in the maple, maize, the beet-root, and mango, and is economically obtained from these to a considerable extent, yet it is not sufficiently pure to admit of ready separation from the foreign matter combined with it, at least by the simple mechanical means which the ordinary producers usually have at command; unless carried on to a large extent, and with suitable machinery and chemical knowledge and appliances. The different species of commercial sugar usually met with in England are four, viz:—brown, or muscovado sugar (commonly called moist sugar); clayed sugar; refined or loaf sugar, and sugar candy; these varieties are altogether dependent on the difference in the methods employed in their manufacture.

The cultivation of the sugar cane, and the manufacture of sugar, were introduced into Europe from the East, by the Saracens, soon after their conquests, in the ninth century.

The common sugar cane is a perennial plant, very sensitive to cold, and is, therefore, restricted in its cultivation to regions bordering on the tropics, where there is little or no frost. In the Eastern hemisphere its production is principally confined to situations

favorable to its growth, lying between the fortieth parallel of north latitude and a corresponding degree south. The cultivation of this plant is principally confined to the West Indies, Venezuela, Brazil, Mauritius, British India, China, Japan, the Sunda, Philippine, and Sandwich Islands, and to the southern districts of the United States. The varieties most cultivated in the latter are the striped blue and yellow ribbon, or Java, the red ribbon, violet, from Java, the Creole, crystalline or Malabar, the Otaheite, the purple, the yellow, the purple-banded, and the grey canes. The quantity of sugar produced on an acre varies from five hundred to three thousand pounds, averaging, perhaps, from eight hundred to one thousand pounds.

Six to eight pounds of the saccharine juice of the plant, yield one pound of raw sugar; from 16 to 20 cartloads of canes, ought to make a hogshead of sugar, if thoroughly ripe. The weight necessary to manufacture 10,000 hhds. of sugar, is usually estimated at 250,000 tons, or 25 tons per hhd. of 15 or 16 cwt.

43–44	125,178	78,943	204,121	202,259
44–45	122,639	81,959	204,598	206,999
45–46	142,384	102,690	245,074	244,030
47–48	164,646	125,829	290,475	289,537
48–49	139,868	107,844	247,712	308,131
49–50	142,203	121,850	264,053	296,119
50–51	129,471	119,317	248,788	305,616
51–52	148,000	110,000	258,000	312,778

The above figures refer to raw sugar only. At these periods, calculating from 1838-39, the duty on British sugar ranged from 24s. down to 10s. per cwt., and foreign slave-grown sugar from 63s. down to 14s. The greatest impetus was given to foreign sugar, when the duties were reduced, in 1846.

The average annual quantity of cane sugar produced and sent into the markets of the civilised world, at the present time, may be taken at 1,500,000 tons, exclusive of the amount grown and manufactured for local consumption in India, China, Cochin-China, and the Malay Archipelago, of which no certain statistics exist, but which has been estimated at about another million tons. So far back as 1844, the Calcutta "Star," in an article on sugar, estimated the domestic consumption in India, at 500,000 tons. This may be considerably below the mark, even if India is taken in its limited signification, as including only British subjects. On this estimate the 94,000,000 of British subjects, men, women and children, would not individually consume more than one pound avoirdupois by the month. A Brahmin, at any of the festivals given by the great, will digest for his own share a large quantity without at all embarrassing his stomach.

Assuming the million and a half of tons that find their way into civilized markets, to represent an average value at the place of production of £15 per ton, we have here the representation of £22,500,000 sterling. But this value may fairly be increased by one-fourth. The whole exportable production of the sugar-growing countries was found to be, in 1844, about 780,000 tons, of which Cuba furnished 200,000 tons. In 1845, notwithstanding Cuba only produced 80,000 tons, the increase from others sources was so considerable namely:—the British Colonial supply 40,000, United States 40,000, Porto Rico 15,000, Brazil 10,000 tons that the total produce fell very little short of the previous year—having reached 764,000 tons. The present supply of sugar to the markets of Europe, is nearly as follows:—

	Cwts.
England,.....	8,000,000
France.....	2,550,000
German League.....	1,350,000
Prussia,..	220,000
Austria (ten Provinces)....	560,000
Belgium..... ...	294,000

The whole annual production of the world is estimated by another party at 1,471,000,000 lbs., of which the United States produced 150,000,000 lbs., including 40,000,000 lbs. of maple sugar. Of the whole amount of sugar produced, Europe consumes about 648,700 tons, divided nearly as follows:—

	lbs.
Great Britain.....	803,360,096
France.....	160,080,000
Belgium.....	19 840,000
Netherlands.....	42,000,000
Russia.....	70,000,000
Denmark and Sweden...	22,000,000
German Zollverein.....	101,300,000
Other parts of Germany	160,000,000
Austria.....	50,000,000
	4,428,580,096

The consumption of sugar then in the whole world may be roughly estimated at two and a half million tons, of which the United Kingdom may now be put down for 350,000; the rest of Europe 420,000, and the United States 300,000.

The production of sugar in the last four years may be stated comparatively as follows :—

Cane Sugar.	1849	1850	1851.	1852.
	Tons.	Tons.	Tons.	Tons.
Cuba	220,000	250,000	252,000	320,000

Mauritius.—In the year 1813, the exports of sugar from this island were but 549,465 lbs., and increasing gradually to 128,476,547 lbs. in 1849, or two-hundred fold in thirty-six years. The equalisation of the duties in 1825, and the admission of Mauritius sugars into England on the same footing as those from the West Indies, had the effect of stimulating the sugar trade of Mauritius, and advancing it to its present remarkable success. Notwithstanding its immense crops, scarcely more than three-fifths of the island is yet under cultivation ; but it has the advantage of a cheap and abundant supply of labor, and much improved machinery has been introduced. The planters first commenced introducing Coolies in 1835, and were for some time restricted to the single port of Calcutta for their supply. The recent advices from Mauritius furnish some interesting information regarding the progress making in the sugar production of that colony. In reference to the cultivation of the cane, it is stated that by the introduction of guano upon several estates in the interior, the production has been very largely increased ; but as the value and economy of manure has not been hitherto sufficiently estimated, its introduction has not been so general as could be desired. The importance of free labor to the cultivation of the estates, has now become fully appreciated by the planters ; it being found that an equal amount of work can be obtained by this means from a less number of hands, and that at lower rates of wages than were current in previous years, the average of which is shown in the following table :—

Years.	Number of Coolies employed.	Aggregate amount of wages paid per week.	Average wages per head per week.	
		£	s.	d.
1846	47,733	33.484	14	0
1847	48,314	35,338	14	9
1848	41 777	26,627	12	9
1849	45,384	27 625	12	2
1850	47,912	31,664	12	3
1851	42.275	27,832	12	2

In 1826, to make from 25 to 30,000,000 lbs. of sugar, it required 30,000 laborers (slaves) ; at the present time, with less than 45,000 (from which number fully 5,009 must be deducted as absent from work from various causes), 135,000,000 lbs. are produced, or about five times the quantity under slavery. The coolies are found to be an intelligent race, who have become inured to the work required, and by whose labor this small island can produce the fifth part of the consumption of the United Kingdom, and that with only about 70,000 acres under cane cultivation. About 10,000 male immigrants, introduced since 1843, are not now working under engagement, but are following other occupations, and thus become permanent consumers. Some cultivate land on a small scale, on their own account, but very few plant canes, as it requires from eighteen to twenty months before they obtain any return for their labor ; but the most important fact established by this and other official statements is, that only a small number of immigrants leave the colony at the expiration of their industrial residence. In the manufacture of sugar from the cane, considerable improvement has been effected by the introduction of new methods of boiling and grinding. The vacuum pan and the system of Wetsell are all tending to economise the cost of production, and to save that loss which for years amounted, in grinding alone, to nearly one-third of the juice of the cane. The planters begin to find that they can increase the value of their sugar 30 to 40 per cent. by these improvements, and that their future prosperity depends upon carrying them out. Unfortunately, however, here, as in many other of our colonies, a very large number of planters do not yet appreciate the advantages to be obtained by the adoption of improved machinery and manufacture, or by improved cultivation, and still struggle on under the old system of waste and negligence, which can only result in the ruin and destruction of their property. In 1827, the number of sugar estates in operation in Mauritius, were 49 worked by water power, 50 by cattle or horses,

and 22 by steam--total 111 ; in 1836, this number had increased to 186, viz.—64 moved by water power, 10 by horse, and 112 by steam. In 1839, the number was 211, of which 138 were worked by steam power—70,292 acres were then under cultivation with sugar. There are now about 490 sugar estates, whereof only 231 have mills—42 are worked by water power, the rest by steam. The annual Mauritius crops, as exported, for the last ten years, have been as follows. The shipments frequently extend beyond a year, hence a discrepancy sometimes between the year's crop and the year's export :—

1842-43	24,400	1847-48	59,021
1843-44	28,600	1848-49	50,782
1844-45	37,600	1849-50	51,811
1845-46	49,100	1850-51	55,000
1846-47	64,100	1851-52	65,800

Besides its exports to Great Britain, Mauritius ships large quantities of sugar to the Cape of Good Hope and Australia. Its local consumption is moreover put down at about 2,500 tons. The progressive increase in its exports is marked by the following return of imports into Great Britain from the island :—

	cwt.		cwt.
1826	93.723	1839	604,671
1827	186,782	1840	690,294
1828	204,344	1841	545 356
1829	361,325	1842	716,009
1830	297,958	1843	696,652
1831	485,710	1844	545,415
1832	517 553	1845	716,173
1833	521 904	1846	845,197
1834	516,077	1847	1,193.571
1835	[illegible]8,891	1848	886.184
1836	558,237	1849	893,524
1837	497,302	1850	1 003,296
1838	537,455	1851	999,337

Java.—Attention has been withdrawn, in a great measure, from sugar cultivation in Java, owing to coffee being found a more remunerative staple. The following figures serve to show the extent of its exports of sugar : —

	cwt.		cwt.
1826	23,565	1838	873 056
1827	38,357	1839	999,895
1828	31,301	1840	1,231,135
1829	91,227	1841	1,252,041
1830	129,300	1842	1,105,856
1831	144.077	1843	1,162,211
1832	292.705	1844	1,260,790
1833	151 128	1845	1 812,500
1834	443,911	1848	1,798,612
1835	523,162	1850	1,797,874
1836	607,336	1851	1,987.957
1837	820,063	1852	2,090,845

In 1840 England imported from Java 75,533 cwt.: in 1841, 87,342 cwt. ; in 1842, 24,922 cwt. ; in 1843, 35,161 cwt. ; and in 1844, about 72,000 cwt. ; but most of this was only sent to Cowes, for orders, to be transhipped to the Continent.

Philippines.—The Exports from Manila into great Britain in 1841, were 133,482 cwt. : in 1842, 63,464 cwt. ; and in 1843, 48,977 cwt. In the fifteen years between 1835 and 1850, the export of sugar from the Philippine Islands more than doubled :—

	Tons.		Tons.
1835	11,542	1841	15 321
1836	14.875	1842	18,540
1837	12 293	1843	22 239
1838	12,375	1844	21,528
1839	15,631	1845	24,500
1840	16,563	1850	28,745

About a third of this is raw sugar, the rest is clayed or refined. It is singular, that though these islands belong to Spain, the export of this staple product to that country should be limited to about 600 tons ; America taking about one-sixth, and England and her colonies the remainder. There is now an increased demand for the Australian colonies, consequent upon the large influx of population to that quarter.

Export of sugar from Manila in 1850.

	Piculs.

Sugar cane.—The sugar cane occurs in a wild state on many of the islands of the Pacific, but in no part of the American continent, notwithstanding a contrary opinion has been expressed.

The following are the chief varieties cultivated in the West Indies, Louisiana, the East Indies, and Mauritius :—

1. Common or creole cane, so called from being introduced from the New World.
2. Yellow Bourbon.
3. Yellow Otaheite.
4. Otaheite with purple bands.
5. Purple Otaheite.
6. Ribbon cane.

Mr. L. Wray, in his "Practical Sugar Planter," considers the Bourbon, and yellow, or straw-coloured Otaheite cane, as identical, but merely altered by change of soil and climate. The yield from these cane-plants seems to be about the same in either Indies, viz., in good land about two-and-a half tons of dry sugar per acre—sometimes three tons.

A very large species of red cane, grown at Gowhatty, in Assam, is made favorable mention of for its strength of growth, early maturity, and juiciness ; and Mr. Wray strongly recommends the introduction into the West Indies of another fine variety, generally grown in the Straits' Settlements, where it is known by the name of the Salangore cane. He considers they would ratoon better than any other cane, and the return from it is on the average 3,600 lbs. of dry sugar to the acre.

"For my own part, he says, I have always reckoned as an average, 3,600 lbs. of dry sugar to the acre as the return this cane will give, on anything like good land, in the Straits, according to the present imperfect mode of expressing and manufacture; but, considering the surpassing richness of land in the West India Islands, Demerara, and Mauritius, I should not be in any way surprised to find that it would there give even three tons an acre. The Salangore cane grows firm and stong; stands upright much better than the Otaheite; gives juice most abundantly, which is sweet and easy of clarification, boils well, and produces a very fine, fair sugar, of a bold and sparkling grain."

Much discussion has arisen on the subject of raising the sugar cane from seed, and the possibility has been universally denied among the planters and agricultural societies of the West India colonies. Mr. Pritchard, a sugar planter of Louisiana, in the "United States Patent Report for 1850," however, states:—"It is an error to suppose that the cane cannot be propagated from the seed. This may be the case when the seed is obtained from plants that have been produced for a number of years from buds, or eyes. All plants that have been produced in this way for a series of years, lose the faculty of forming prolific seeds; and the sugar cane is governed by the same laws which govern the whole vegetable kingdom. It cannot, therefore, be expected to produce seeds after it has been cultivated for a great length of time."

India.—Sugar is a very old and extensive cultivation in India. It would propably be within the mark, to estimate the annual produce of the country at a million of tons. An official return showed that the quantity of sugar carried on one road of the interior, for provincial consumption, was about equal to the whole quantity shipped from Calcutta—some 50,000 or 60,000 tons. India is fast becoming a great sugar producing country, although its produce and processes of manufacture are rude and imperfect. The Coolies who return from time to time to the India ports, bring with them much acquired knowledge and experience from the Mauritius. In 1825, the import of sugar from the East Indies was but 146,000 cwt, and it fluctuated greatly in succeeding years, being occasionally as low as 76,600 cwt. In 1837 the quantity imported was just double what it was in 1827. In 1841, it had reached as high as 1,239,738 cwt., and subsequently kept steady for a few years at 1,100,000 cwt.—and for the last four years ending 1851, has averaged 1,400,000 cwt.

Some years since, (*Report, 18th December*, 1822) the East India Company instituted inquiries relative to the cultivation of the sugar cane in Hindostan, and the information obtained was published in a large folio volume. The Reports furnished by their officers, from almost every district, concur in stating that there were three kinds cultivated:—1, The purple. 2. The white. 3. A variety of the white, requiring a large supply of water. The epitome of the Reports affords this information:—

1. *The purple coloured cane* yields a sweeter, richer juice, than the yellow or light coloured, but in less quantity, and is harder to press. Grows on dry lands. Scarce any other sort in Beerbhoom, much in Radnagore, some about Santipore, mixed with light colored cane. Grows also near Calcutta; in some fields separate, in others mixed with pooree or light colored cane. When eaten raw, is more dry and pithy in the mouth, but esteemed better sugar than the pooree, and appears to be the superior sort of cane. Persons who have been West Indian planters do not know it as a West Indian cane.

2. *The light colored cane*, yellow, inclining to white; deeper yellow when ripe, and on rich ground, it is the same sort as that which grows in the West India Islands; softer, more juicy than the Cadjoolee, but juice less rich, and produces sugar less strong; requires seven maunds of pooree juice to make as much goor or inspissated juice as is produced from six of the Cadjoolee. Much of this kind is brought to the Calcutta markets, and eaten raw.

3. *The white variety*, which grows in swampy lands, is light colored, and grows to a great height. Its juice is more watery, and yields a weaker sugar than the Cadjoolee. However, as much of Bengal consists of low grounds, and as the upland canes are liable to suffer from drought it may be advisable to encourage the cultivation of it, should the sugar it produces be approved, though in a less degree than other sugars, in order to guard against the effects of dry seasons. Experience alone can determine how far the idea of encouraging this sort may answer. Besides the foregoing, several kinds are now known to the Indian planter. One of them, the China sugar cane, was considered by Dr. Roxburgh to be a distinct species, and distinguished by him as *Saccharum sineuse*. It was introduced into India in 1796, by Earl Cornwallis, as being superior to the native kinds. It is characterised by a hardness which effectually resists most of the country rude mills; but this hardness is importantly beneficial, inasmuch as that it withstands the attack of the white ants, hogs, and jackals, which destroy annually a large portion of the common cane. *Reports of Dr. Roxburgh, Mr. Touchet of Radanagore, and Mr. Cardia of Mirsapore, Cutna, Papers on the India Sugar, page 258.*

Mysore.—Dr. Buchanan found four kinds known in Mysore. Two of these are evidently the purple and white generally known; but as this is not distinctly stated, Mr. Simmond has retained the form in which he

notices them. *Restali*, the native sugar of the Mysore, could only be planted in the last two weeks of March and two first of April. It completes its growth in twelve months, and does not survive for a second crop. Its cultivation has been superseded by others.

Puttaputti.—This was introduced from Arcot, during the reign of Hyder Ali. It is the only one from which the natives can extract sugar; it also produces the best *Bella* or *Jaggery*. It can be planted at the same season as the other, as well as at the end of July and beginning of August. It is fourteen months in completing its growth; but the stools produce a second crop, like the ratoons of the West Indies, which ripen in twelve months.

Maracabo, Cuttaycabo.—These two are very small, seldom exceeding half an inch diameter; yet in some districts of Mysore, as about Colar, the last-named is the variety usually cultivated; but this arises from its requiring less water than the larger varieties. The best varieties are those introduced from the Islands of Otaheite and Bourbon. Hindostan is indebted for their introduction to Captain Sleeman, who brought them hither from the Mauritius in 1827. He committed them to Dr. Wallich, under whose care, at the Botanic Garden, they have flourished, and been the source from whence the benefit has been generally diffused. Their superiority over those which have been usually cultivated by the natives has been completely established. The largest of the Hindoostan canes, ripe and trimmed ready for the mill, has never been found to exceed five pounds; but it is not uncommon for an Otaheite cane, under similar circumstances, to weigh seven pounds. [Many are of opinion, that although the juice of this cane is larger in quantity, yet that it contains less sugar. There is some sense in the reason they assign, which is, that in the Mauritius and elsewhere it has the full time of twelve or fourteen months allowed for its coming to maturity—whereas the agriculture of India and especially in Bengal, only allows it eight or nine months, which, though ample to mature the smaller country canes, is not sufficient for the Otaheite.] The extra weight arises proportionately from an increased secretion of superior sap. The sugar is more abundant, granulates more readily, and has less scum. Other superior qualities are, that the canes ripen earlier, and are less injured by the occurrence of protracted dry weather. Of the history of the sugar cane a popular tradition obtains amongst the natives, that, in very ancient times, a vessel belonging to their country chanced by accident to leave one of her crew, under a desperate fit of sickness at a desert island at a considerable distance in the Eastern Seas, and that, returning by the same route, curiosity prompted them to inquire after the fate of their companion, when, to their utter astonishment, the man presented himself to their view, completely recovered from his sickness, and even in a state of more than common health. With anxiety they inquired for the physic he had so successfully applied, and were conducted by him to the sugar cane, on which he acquainted them he had solely subsisted from the time of their departure. Attracted by such powerful recommendation, every care and attention was bestowed, we may suppose, to convey such an invaluable acquisition to their own lands, where the soil and climate have mutually since contributed to its present prosperity.

Soil.—The soil best suiting the sugar cane is aluminous rather than the contrary, tenacious without being heavy, readily allowing excessive moisture to drain away, yet not light. One gentleman, Mr. Ballard, has endeavoured to make this point clear by describing the most favorable soils about Gazepore as "*light clays*," called there *Mootearee*, or *doansa* according as there is more or less sand in their composition.—*Trans. Agri-Hort. Soc.* i. 121. Mr. Peddington seems to think that calcareous matter, and iron in the state of *peroxide*, are essential to be present in a soil for the production of the superior sugar cane. There can be no doubt that the calcareous matter is necessary, but experience is opposed to his opinion relative to the peroxide. The soil preferred at Radnagore is there distinguished as the soil of "two qualities," being a mixture of rich clay and sand, and which Mr. Touchet believed to be known in England as a light brick mould. About Rungpore, Dinajpore, and other places where the ground is low, they raise the beds where the cane is to be planted four or five feet above the land adjacent. The experience of Dr. Roxburgh agrees with the preceding statements. He says, "The soil that suits the cane best in this climate is a rich vegetable earth, which on exposure to the air readily crumbles down into very fine mould. It is also necessary for it to be of such a level as allows of its being watered from the river by simply damming it up (which almost the whole of the land adjoining to this river, the Godavery, admits of), and yet so high as to be easily drained during heavy rains. Such a soil, and in such a situation, having been well meliorated by various crops of leguminous plants, or following, for two or three years, is slightly manured, or has had for some time cattle pent upon it. A favourite manure for the cane with the Hindoo farmer is the rotten straw of green and black pessaloo (*Phaseolus mungo, max.*)" Roxburgh on the Culture of Sugar and Jaggary in the Rajahmundry Circar; Third Ap. to Report on East India Sugar, p. 2. Many accordant opinions might be added to the preceding, but it seems only necessary to observe further that the sugar cane requires a soil sufficiently elevated to be entirely free from inundation,

but not so high as to be deprived of moisture, or as to encourage the production of white ants (*termes*). The sugar cane is an exhausting crop, and it is seldom cultivated by the ryot more frequently than once in three or four years on the same land. During the intermediate period, such plants are grown as are found to improve the soil, of which, says Dr. Tennant, the Indian farmer is a perfect judge. They find the leguminous tribe the best for the purpose. Such long intervals of repose from the cane would not be requisite if a better system of manuring were adopted.

Mr J. Prinsep has recorded the following analysis of three soils distinguished for producing sugar. They were all a soft, fine-grained alluvium, without pebbles. No. 1 was from a village called Mothe, on the Sarjee, about ten miles north of the Ganges, at Buxar, and the others from the south bank of the Ganges, near the same place. There is a substratum of *kunkar* throughout the whole of that part of the country, and to some mixture of this earth with the surface soil the fertility of the latter is ascribed :—

	1	2	3
Hygrometric moisture, on drying at 212 deg.	2·5	2·1	3·6
Carbonaceous and vegetable matter, on calcination....	1·8	2·1	4·0
Carbonate of lime (No. 3 effervesced.)	1·6	0·6	3·9
Alkaline salt, soluble.	1·0	1·1	0·3
Silex and alumina.	94·1	94.1	88·2
	100·0	100·0	100.0

The earths unfortunately were not separated. Mr. Prinsep says the two first were chiefly of sand, and the third somewhat argillaceous. The former required irrigation, but the other was sufficiently retentive of moisture to render it unnecessary.—(Journ. Asiatic Soc., ii. 435.)

Manures.—The sugar cane being one of the most valued crops of the ryot, he always devotes to it a portion of the fertilising matter he has at command, though in every instance this is too small. In the Rajahmundry district, previously to planting, the soil is slightly manured, either by having cattle folded upon it, or by a light covering of the rotten straw of the green and black pessalloo, which is here a favourite fertiliser. In some parts of Mysore the mud from the bottom of tanks is employed, and this practice is more generally adopted in other places. Thus the fields being divided by deep ditches in Dinajpoor, the mud from which is enriched by the remains of decayed aquatic plants and animals, forms an excellent manure for the sugar cane, and of this the ryots make use, spreading it over the surface before the ploughing is commenced; and when that operation is completed, the soil is further fertilised by a dressing of oilcake and ashes. Crushed bones would unquestionably be of the greatest benefit if applied to the sugar cane crop. Not only would their animal matter serve as food for the plants, but the phosphate of lime of the bones is one of the chief saline constituents of the sugar cane.

Salt is said to be valuable manure for this crop. Dr. Nugent, in a Report made to the Agricultural Society of Antigua, observes that salt has been found a valuable auxiliary in cultivating the sugar cane. Many trials of it, he says, have been made during successive seasons applied generally to the extent of about nine or ten bushels per acre. It destroys grubs and other insects, and give the canes an increased vigor and ability to resist drought. It is a singular remark of the intelligent traveller, M. de Humboldt, while speaking of the practice adopted in the Missions of the Orinoco, when a coco-nut plantation is made, of throwing a certain quantity of salt into the hole which receives the nut ; that of all the plants cultivated by man there are only the sugar cane, the plantain, the mammee, and the Avocada pear, which endure equally irrigation with fresh and salt water.

In the West Indies, when the cane is affected by what is called there the *blast*, which is a withering or drying up of the plants, an unfailing remedy is found to be watering them with an infusion of dung in salt water [L'Explotation de Sucreries.] Porter on the sugar canes. 35, 321.

Preparation of soil.—In the *Rajahmundry* district, during the months of April and May, the ground isfrequently ploughed, until brought into a very fine tilth. About the end of May, or beginning of June, the rains usually commence, and the canes are then to be planted. If the rains do not set in so early, the land is flooded artificially, and when converted into a soft mud, whether by the rain or by flooding, the canes are planted.

In *Mysore*, the ground is watered for three days, and then, after drying for the same period, ploughing commences, this operation being repeated five times during the following eight days. The clods during this time are broken small by an instrument called *col kudali*. The field is then manured and ploughed a sixth time. After fifteen days it is ploughed again, twice in the course of one or two days. After a lapse of eight days it is ploughed a ninth time. Altogether these operations occupy about forty-four days. For planting, which is done in six days, an implement called *yella kudali* is employed.

In *Dinajpoor*, " the field, from about the middle of October until about the 10th of January, receives ten or twelve double ploughings, and after each is smoothed with the *mogi*. During the last three months of this time it is manured with cow-dung and mud from ponds and ditches. On this account, the land fit for sugar cane is generally divided into fields by wide ditches, into which much mud is washed

by the rain, and is again thrown on the fields when the country dries, and leaves it enriched by innumerable aquatic vegetables and animals that have died as the water left them. When the ploughing has been completed, the field is manured with ashes and oilcake."

About *Malda*, "the land is first ploughed in the month of Cartick, length and breadth ways, and harrowed in like manner; four or five days after it is again ploughed and harrowed, as before, twice. In the month of Aghun, the whole land is covered with fresh earth, again twice ploughed, and harrowed in different directions, and then manured with dung. Fifteen or twenty days afterwards it is to be twice ploughed, as before; eight or ten days after which, it is to be slightly manured with dung and the refuse of oil, mixed together; then twice ploughed and harrowed in different directions, so that the clods of earth brought be well mixed together with the land. This preparation continues until the 20th or 25th of the month Poons."

In the vicinity of *Dacca*, during "Cautic or Augun (October, November) the Ryots begin to prepare their ground. They first dig a trench round their fields, and raise a mound of about three feet in height. If the ground to be cultivated is waste, about nine inches of the surface are taken off, and thrown without the enclosure. The ground is ploughed to the depth of nine inches more. The clods are broken, and the earth made fine. In Maug or Faugun (January, February) the sugar cane is planted; a month afterwards earth is raised about the plants; after another month this is repeated. The crop is cut in Poous and Maug (December, January). If the ground be not waste, but cultivated, the surface is not taken off. After cutting the crop, it is not usual again to grow sugar cane on the same ground for eighteen months, on account of the indifferent produce afforded by a more early planting.

In the Zillah, *North Mooradabad*, the land is broken up at the end of June. After the rains have ceased it is manured, and has eight or ten ploughings. This clears it of weeds. In February it is again manured and ploughed four or five times, and just before the sets are planted some dung, four cart-loads to each cutcha beegah of low land, and five cart-loads to high land, are added. The land is well rolled after the four last ploughings, and again after the cuttings are set.

About *Benares* and the neighbouring districts, Mr. Haines says, that owing to the hot winds which prevail "from March until the setting in of the annual rains in June or July, the lands remain fallow till that period. In the mean time, those fields that are selected for sugar cane are partially manured by throwing upon them all manner of rubbish they can collect, and by herding their buffaloes and cattle upon them at night, though most of the manure from the latter source is again collected and dried for fuel. When the annual rains have fairly set in, and the Assarree crops sown (in some instances an Assarree crop is taken from the lands intended for sugar cane), they commence ploughing the cane lands, and continue to do so four or five times monthly (as they consider the greater number of times the fields are turned up at this period of the season, the better the crop of cane will be), till the end of October, continuing to throw on the little manure they can collect. Towards the end of October, and in November, their ploughs are much engaged in sowing their winter (or rubbee) crops of wheat, barley, grain &c.; and at this period they make arrangements with the shepherds who have large flocks of sheep, to fold them upon the fields at night, for which they pay so much per beegah in grain. During the latter part of November, and early in December, the fields are again ploughed well, and all grass, weeds, &c., removed with the hoe; then the surface of the field is made as smooth as possible by putting the "*hengah*" (a piece of wood eight to ten feet in length, and five to six inches in breadth, and three or four inches in thickness, drawn by two pairs of bullocks, and the man standing upon the wood to give it weight), over several times for three or four days in succession. This makes the surface of the field very even and somewhat hard, which prevents the sun and dry west wind from abstracting the moisture, which is of great importance at this period of the season, for, should there be no rain, there would not be sufficient moisture at the time of planting the cane to cause vegetation. In this state the land remains till the time of planting the cane cuttings, which is generally the 1st to the 15th of February; but should there have been a fall of rain in the mean time, or excess of moisture appear, the field is again ploughed, and the hengah put over as before. A day or two previous to planting the cane, the field is ploughed and the hengah lightly put over."—(Trans. Agri-Hort. Soc. vi. 4, 5.)

Sets.—When the canes are cut at harvest time, twelve or eighteen inches of their tops are usually taken off, and stored, to be employed for sets. Each top has several joints, from each of which a shoot rises, but seldom more than one or two arrive at a proper growth. When first cut from the stem, the tops intended for plants are tied in bundles of forty or fifty each, and are carefully kept moist. In a few days they put forth new leaves: they are then cleared of the old leaves, and separately dipped into a mixture of cowdung, pressed mustard seed, and water. A dry spot is prepared, and rich loose mould and a small quantity of pressed mustard seed; the plants are separately placed therein, a small

quantity of earth strewed amongst them, and then covered with leaves and grass to preserve them from heat. Ten or twelve days afterwards they are planted in the fields.

In *Burdwan*, the tops, before they are planted, are cut into pieces from four to six inches long, so that there are not more than four knots in each. Two or three of these plant tops are put together in the ground, and a beegah requires from 7,500 to 10,240 plants.

In *Rungpore* and *Dinajpoor*, about 9,000 plants are required for a beegah, each being about a foot in length.

In *Beerbhoom*, 8,000 plants are said to be requisite for a beegah, each cane top being about fifteen inches long.

Near *Culcutta*, from 3,000 to 8,000 plants are required for a beegah according to the goodness of the soil, the worse soil needing most plants.

In *Mysore* an acre contains 2,420 stools, and yields about 11,000ripe canes.

Near *Rajamundry* about 400 cuttings are planted on a cutcha beegah (one-eighth of an acre).

In Zilla, *North Mooradabad*, 4,200 sets, each eight inches long, are inserted upon each cutcha beegah of low land, and 5,250 upon high land.

In the district of *Gollagore* the Ryots cut a ripe cane into several pieces, preserving two or three joints to each, and put them into a small bed of rich mould, dung, and mustard-seed from which the oil has been expressed.

At *Radnagore*, when the time of cutting the canes arrives, their tops are taken off, and these are placed upright in a bed of mud for thirty or forty days, and covered with leaves or straw. The leaves are then stripped from them, and they are cut iuto pieces, not having less than two nor more than four joints each. These sets are kept for ten or fifteen days in a bed prepared for them, from whence they are taken and planted in rows or three together, eighteen inches or two feet intervening between each stool.

Planting.—The time and mode of planting vary.

In the *Rajahmundary Circar*, Dr. Roxburgh says, that "during the months of April and May the land is repeatedly ploughed with the common Hindoo plough, which soon brings the loose rich soil (speaking of the Delta of the Godavery) into very excellent order. About the end of May and beginning of June, the rains generally set in, in frequent heavy showers. Now is the time to plant the cane; but should the rains hold back, the prepared field is watered or flooded from the river, and, while perfectly wet, like soft mud, the cane is planted. "The method is most simple. Laborers with baskets of the cuttings, of one or two joints each, arrange themselves along one side of the field. They walk side by side, in as straight a line as their eye and judgment enable them, dropping the sets at the distance of about eighteen inches asunder in rows, and about four feet from row to row. Other laborers follow, and with the foot press the set about two inches into the soft, mud-like soil which, with a sweep or two with the sole of the foot, they most easily and readily cover."—(Roxburgh on the Culture of Sugar.)

About *Malda*, in the month of Maug (January, February), the land is to be twice ploughed, and harrowed repeatedly, length and breadth ways; after which it is furrowed, the furrows half a cubit apart, in which the plants are to be set at about four fingers' distance from each other, when the furrows are filled up with the land that lay upon its ridges. The plants being thus set, the land is harrowed twice in different directions; fifteen or twenty days afterwards the cane begins to grow, when the weeds which appear with it must be taken up; ten or twelve days after this the weeds will again appear. They must again be taken up, and the earth at the roots of the canes be removed, when all the plants which have grown will appear.

At *Ghazepore* the rains set in at the beginning of March, and planting then commences.

Near *Calcutta* the planting takes place in May and June.

In *Dinajpoor* and *Rungpore* the planting time is February.

About *Commercolly* it is performed in January. The field is divided into beds six cubits broad, separated from each other by small trenches fourteen inches wide and eight inches deep. In every second trench are small wells, about two feet deep. The irrigating water flowing along the trenches fills the wells, and is taken thence and applied to the canes by hand. Each bed has five rows of canes. The sets are planted in holes about six inches in diameter, and three deep; two sets, each having three joints, are laid horizontally in every hole, covered slightly with earth, and over this is a little dung. When the canes are planted in the spring, the trenches must be filled with water, and some poured into every hole. At the other season of planting the trenches are full, it being rainy weather; but even then the sets must be watered for the first month.

Mr. Haines says that in *Mirzapore* and the neighbouring districts, "in planting the cane, they commence a furrow round the field, in which they drop the cuttings. The second furrow is left empty; cuttings again in the third; so they continue dropping cuttings in every second furrow till the whole field is completed, finishing in the centre of the field. The field remains in this state till the second or third day, when for two or three days in succession it is made even and hard upon the surface with the hengah, as before stated."—(Trans. Agri-Hort. Soc. vi. 5.)

Bombay.—Mr. Vaupell, in describing the most successful mode of cultivating the *Mauritius* sugar cane in Bombay, says, that "after the ground is levelled with the 'paur,' in the manner of the cultivators, pits of two feet in diameter, and two feet in depth, should be dug throughout the field at the distance of five feet apart, and filled with manure and soil to about three inches of the surface. Set in these pits your canes, cut in pieces about a foot and a half long laying them down in a tringular form, thus ▲. Keep as much of the eyes or shoots of the cane uppermost as you can; then cover them with manure and soil; beds should next be formed to retain water, having four pits in each bed, leaving passages for watering them. The cutting should be watered every third day during hot weather, and the field should always be kept in a moist state."—(Ibid. iii 43.)

About *Benares*, the sets require, after planting, from four to six waterings, until the rains commence, and as many hoeings to loosen the surface, which becomes caked after every watering. The moister nature of the soil renders these operations generally unnecessary in Bengal.

After-culture.—In *Mysore*, the surface of the earth in the hollows in which the sets are planted is stirred with a stick as soon as the shoots appear, and a little dung is added. Next month the daily watering is continued, and then the whole field dug over with the hoe, a cavity being made round each stool, and a little dung added. In the third month water is given every second day: at its close, if the canes are luxuriant, the ground is again dug; but if weakly, the watering is continued during the fourth month before the digging is given. At this time the earth is drawn up about the canes, so as to leave the hollows between the rows at right angles with the trenches. No more water is given to the plants, but the trenches between the beds are kept full for three days. It is then left off for a week, and if rain occurs, no further water is requisite; but if the weather is dry, water is admitted once a week during the next month. The digging is then repeated, and the earth levelled with the hand about the stools. The stems of each stool are ten or twelve in number, which are reduced to five or six by the most weakly of them being now removed. The healthy canes are to be tied with one of their own leaves, two or three together, to check their spreading; and this binding is repeated as required by their increased growth. In the absence of rain, the trenches are filled with water once a fortnight. When the *Putta putti* is to be kept for a second crop, the dry leaves cut off in the crop season are burnt upon the field, and this is dug over, and trenches filled with water, and during six weeks the plants watered once in every six or eight days (unless rain falls), and the digging repeated three times, dung being added at each digging. The after-culture is the same as for the first crop.

In the *Upper Provinces*, Dr. Tennant says, if moderate showers occur after planting, nothing more is done until the shoots from the sets have attained a height of two or three inches. The soil immediately around them is then loosened with a small weeding iron, something like a chisel; but if the season should prove dry, the field is occasionally watered; the weeding is also continued and the soil occasionally loosened about the plants. In August, small trenches are cut through the field, with small intervals between them, for the purpose of draining off the water, if the season is too wet. This is very requisite, for if the canes are now supplied with too much moisture, the juice is rendered watery and unprofitable. If the season happens to be dry, the same dikes serve to conduct the irrigating water through the field, and to carry off what does not soak into the earth in a few hours. Stagnant water they consider very injurious to the cane, and on the drains being well contrived depends in a great measure the future hope of profit. Immediately after the field is trenched, the canes are propped. They are now about three feet high, and each set has produced from three to six canes. The lower leaves of each are first carefully wrapt up around it, so as to cover it completely in every part; a small strong bamboo, eight or ten feet long, is then inserted firmly in the middle of each stool, and the canes tied to it. This secures them in an erect position, and facilitates the circulation of the air. Hoeing cannot be repeated too frequently. This is demonstrated by the practice of the most successful cultivators.

In Zilla, *N. Mooradabad*, in April, about six weeks after planting, the earth on each side of the cane-rows is loosened by a sharp-pointed hoe, shaped somewhat like a bricklayer's trowel. This is repeated six times before the field is laid out in beds and channels for irrigation. There, likewise, if the season is unusually dry, the fields in the low ground are watered in May and June. This supposes there are either nullahs, or ancient pucka wells, otherwise the canes are allowed to take their chance, for the cost of making a well on the uplands is from ten to twenty rupees—an expense too heavy for an individual cultivator, and not many would dig in partnership, for they would fight for the water.

In the vicinity of *Benares*, as the canes advance in growth, they continue to wrap the leaves as they begin to wither up round the advancing stem, and to tie this to the bamboo higher up. If the weather continue wet, the trenches are carefully kept open; and, on the other hand, if dry weather occurs, water is occasionally supplied. Hoeing is also performed every five or six weeks.

Wrapping the leaves around the cane is found to prevent them cracking by the heat of the sun, and hinders their throwing out lateral branches. In January and February the canes are ready for cutting. The average height of the cane is about nine feet, foliage included, and the naked cane from one inch to one inch and a quarter in diameter.

Near *Maduna*, the hand-watering is facilitated by cutting a small trench down the centre of each bed. The beds are there a cubit wide, but only four rows of canes are planted in each.

It is deserving of notice, that the eastern and north-eastern parts of Bengal are more subject to rain at every season of the year, but especially in the hot months, than the western; which accounts for the land being prepared and the plants set so much earlier in Rungpore than in Beerbhoom. This latter country has also a drier soil generally; for this reason, so much is said in the report from thence of the necessity of watering. The Benares country is also drier than Bengal, therefore more waterings are requisite.

At *Malda*, ten or fifteen days after the earth has been removed from the roots of the canes and the plants have appeared, the land is slightly manured, well cleared of weeds, and the earth that was removed again laid about the canes; after which, ten or fifteen days, it must be well weeded, and again twenty or twenty-five days afterwards. This mode of cultivation it is necessary to follow until the month of Joystee. The land must be ploughed and manured between the rows of canes in the month of Assaar; after which, fifteen or twenty days, the canes are to be tied two or three together with the leaves, the earth about them well cleaned, and the earth that was ploughed up laid about the roots of the canes something raised. In the month of Saubun, twenty or twenty-five days from the preceding operation, the canes are tied as before, and again ten or fifteen days afterwards; which done, nine or ten clumps are then to be tied together.

In the *Rajahmundry Circar*, on the Delta of the Godavery, Dr. Roxburgh states "that nothing more is done after the cane is planted, if the weather be moderately showery, till the young shoots are some two or three inches high; the earth is then loosened for a few inches round them with the weeding iron. Should the season prove dry, the field is occasionally watered from the river, continuing to weed and to keep the ground loose round the stools. In August, two or three months from the time of planting, small trenches are cut through the field at short distances, and so contrived as to serve to drain off the water, should the season prove too wet for canes, which is often the case, and would render their juices weak and unprofitable. The farmer, therefore, never fails to have his field plentifully and judiciously intersected with drains while the cane is small, and before the usual time for the violent rains. Immediately after the field is trenched, the canes are all propped; this is an operation which seems peculiar to these parts. In Dinajpoor, in about a month after planting, "the young plants are two or three inches high; the earth is then raised from the cuttings by means of a spade, and the dry leaves by which they are surrounded are removed. For a day or two they remain exposed to the air, and are then manured with ashes and oilcake, and covered with earth. Weeds must be removed as they spring; and when the plants are about a cubit high, the field must be ploughed. When they have grown a cubit higher, which is between the 13th of June and 14th of July, they are tied together in bundles of three or four, by wrapping them round with their own leaves. This is done partly to prevent them from being laid down by the wind and partly to prevent them from being eaten by jackals. During the next month three or four of these bunches are tied together; and about the end of September, when the canes grow rank, they are supported by bamboo stakes driven in the ground. They are cut between the middle of December and the end of March." If the canes grow too vigorously, developing a superabundance of leaves, it is a good practice to remove those leaves which are decayed, that the stems may be exposed fully to the sun. In the West Indies, this is called *trashing* the canes. It requires discretion; for in dry soils or seasons, or if the leaves are removed before sufficiently dead, more injury than benefit will be occasioned.

Harvesting.—The season in which the canes become ripe in various districts has already been noticed when considering their cultivation. In the Rajahmundry Circar, about the mouth of the Godavery, Dr. Roxburgh adds, "that in January and February the cane begins to be ready to cut, which is about nine months from the time of planting. Their height, when standing on the field, will be from eight to ten feet (foliage included), and the naked cane from an inch to an inch and a quarter in diameter."

In *Malda* the canes are cut in January and February. In N. Mooradabad, upon the low land, the canes are ripe in October, and upon the high lands a month later. The fitness of the cane for cutting may be ascertained by making an incision across the cane, and observing the internal grain. If it is soft and moist, like a turnip, it is not yet ripe; but if the face of the cut is dry, and white particles appear, it is fit for harvesting.—(*Fitzmaurice on the Culture of the Sugar Cane.*)

Injuries.—1. *A wet season*, either during the very early or in the concluding period of the cane's vegetation, is one of the worst causes of

injury. In such a season, the absence of the usual intensity of light and heat causes the sap to be very materially deficient in saccharine matter. But, on the other hand,

2. *A very dry season*, immediately after the sets are planted, though the want of rain may in some degree be supplied by artificial means, causes the produce to be but indifferent. These inconveniences are of a general nature, and irremediable.

3. *Animals.*—In India not only the incursions of domesticated animals, but in some districts, of the wild elephant, buffalo, and hog, are frequent sources of injury. Almost every plantation is liable, also, to the attack of the Jackal, and rats are destructive enemies.

4. *White Ants.*—The sets of the sugar cane have to be carefully watched, to preserve them from the white ant (*Termes*), to attacks from which they are liable until they have begun to shoot. To prevent this injury, the following mixture has been recommended :—

Asafœtida (hing), 8 chittacks.
Mustard-seed cake (sarsum ki khalli), 8 seers.
Putrid fish, 4 seers.
Bruised butch root, 2 seers ; or muddur, 2 seers.

Mix the above together in a large vessel, with water sufficient to make them into the thickness of curds ; then steep each slip of cane in it for half an hour after planting ; and, lastly water the lines three times previous to setting the cane, by irrigating the watercourse with water mixed up with bruised butch root, or muddur if the former be not procurable. That the above application would be beneficial, is rendered still more worthy of credit from the following experience:—In the Dhoon, the white ant is a most formidable enemy to the sugar planter, owing to the destruction it causes to the sets when first planted. Mr. G. H. Smith says, that there is a wood very common there, called by the natives *Butch*, through which, they say, if the irrigating waters are passed in its progress to the beds, the white ants are driven away. (Trans. Agri-Hort. Soc. of India, v. 65.] The experience of farmers in Europe, has however shown that the use of any poisonous dring, to protect the seed or sets, is highly dangerous to the health of those who eat the produce, and the employment of "Butch" or arsenic cannot therefore he recommended. A very effectual mode of destroying the white ant, is by mixing a small quantity of arsenic with a few ounces of burned bread, pulverised flour, or oatmeal, moistened with molasses, and placing pieces of the dough thus made, each about the size of a turkey's egg on a flat board, and covered over with a wooden bowl, in several parts of the plantation. The ants soon take possession of these, and the poison has a continuous effect, for the ants which die are eaten by those which succeed them. (*Fitzmaurice on the Culture of the Sugar Cane.*) They are said to be driven from a soil by frequently hoeing it. They are found to prevail most upon newly broken-up lands.

In *Central India*, the penetration of the white ants into the interior of the sets, and the consequent destruction of the latter, is prevented by dipping each end into buttermilk, asafœtida, and powdered mustard-seed, mixed into a thick compound.

Storms.—Unless they are very violent, Dr. Roxburgh observes, "they do no great harm, because the canes are propped However, if these are once laid down, which sometimes happens, they become branchy and thin, yielding a poor, watery juice.

Maize Sugar.—The stem and branches of Indian corn, during the time that its grain is filling, abounds with sugar, even when grown in England ; so much so, that it might be turned to account by those of the peasantry who have small plots of ground attached to their cottages ; and by a simple method a rich syrup may be obtained from it, equal in sweetness to treacle, and superior to it in flavor. The proper time for cutting down the plant (which should be done within an inch of the ground), is when the corn in the ear is small and full of a milky juice. All the large and old leaves should be stripped off, leaving only the young and tender ones ; they should then be cut into short lengths, thoroughly bruised, and the juice entirely pressed out from them. Where the means cannot be obtained for expressing the juice by this method, the following may be employed :—After the plants have been cut into small pieces, put them into a large pot or copper, with only just sufficient water to extract the juice ; boil for one hour, and then strain off the liquor ; to each gallon of this liquor add a wine-glass full of lime-water whilst warm ; but if it be the expressed juice, obtained as above mentioned, add double the quantity of lime-water. When the liquor is cold, for every three gallons beat up an egg with some of the liquor ; put altogether into a boiler, and boil gently till the syrup acquires the consistence of treacle. Whilst this is going on, the liquor should every now and then be well stirred, and the scum which rises to the surface taken off. This syrup, which will be found a better substitute for sugar than treacle, and more wholesome, should be kept in lightly-covered vessels, in a dry place.—*Extracts from Simmonds, pages 137 to 215.*

Sugar cane, its History.—*Sugar* has, from an early period of the world's history, been used in some form or other as an article of food ; indeed, the practice of sweetening food is more ancient than the knowledge of sugar. The juice of a large number of vegetables owes its sweetness to the presence of sugar.

The ancients used honey for the purpose; and at a later period, when a sweet substance, which exuded from a species of cane, was used, it was termed *mel arundinaceum*. Dioscorides, in the first century, refers to a kind of honey produced by canes growing in India and in Arabia Felix, and named σάκχαρον, or *sugar*. Pliny records the same fact, but remarks that it was used only in medicine. Sugar was not known in Northern Europe as an article of food, until the time of the Crusaders. The sugar-cane was introduced into Cyprus from Asia, and about the year 1148 is said to have been largely cultivated there; at which time it was transplanted to Maderia, and from thence, in 1506, to the West Indies. There is evidence that the sugar-cane was cultivated on the coast of Andalusia before the invasion of the Arabs, in the middle of the fifteenth century. The Arabs had many sugar factories, and with them probably originated the art of boiling down the juice for the production of sugar. The refining of the raw product is of later date, and is referred to a Venetian. In the year 1597, a refinery existed in Dresden.

Sugar making and Refining.—*Sugar-candy* is mentioned in the *Alchemia* of Libanius in 1595. Up to the close of the seventeenth century, syrup and honey were used by the poorer classes in Germany for sugar; and it was not until tea and coffee had come into general use that sugar was regarded as one of the necessaries of life. In the year 1747, Margraf, a German chemist, discovered that cane sugar existed ready formed in the roots of many plants, especially in beet-root; but nearly half a century elapsed before any attempt was made to establish a factory of beet-root sugar; this was done by Achard, at Cunoom, in Silesia, not, however, with any great success. The first energetic impulse that was given to the manufacture was by Napoleon, who, anxious to ruin the colonial trade of Great Britain, ordered the blockade of the continent, and in order to supply the demand for sugar, which formed so important a part of our commerce, he offered premiums for the best methods of separating sugar from beet-root. The chemists of France exerted themselves with their accustomed method and skill. Extensive experiments were made on the cultivation of the beet-root, and the best method of obtaining its juice, and extracting the sugar from it. Factories were soon at work, and the first sample of French beet-root sugar was conveyed at once to the emperor, who received it with joy, placed it under a glass case as one of the choicest ornaments of his drawing-room. The extensive and valuable series of apparatus invented or improved by his subjects, for the preparation of beet-root sugar, adapted by the English, have been the means of saving English colonies, which had prospered in spite of his opposition, but which at a later period, chiefly b the renunciation of slave labour, had bee brought to the verge of ruin.

Chemical Relations of Sugar.—Sugar ma be defined as a substance soluble in wate possessing a sweet taste, and capable undergoing fermentation. There are two leac ing varieties of sugar: one the produce of th *Arundo saccharifera*, or sugar-cane; also foun in beet root, in the sap of certain species of ma ple, in the stems of palms, maize, &c., an known as *crystalline* or *cane-sugar*: the other con tained in grapes, figs, plums, and fruits in gene al, and is known by the several names of *grann lar*, or *grape sugar*, *glucose* or *sugar of fruit* Fruit sugar is however distinguished by som chemists from grape-sugar, as will be notice more particularly hereafter. The property c submitting to the action of ferments and resolv ing itself into carbonic acid and alcohol is pe culiar to fruit or grape-sugar; and whe other varieties of sugar undergo this remarkabl process, they are by the action of ferments firs converted into fruit or grape-sugar, and the undergo fermentation. Cane-sugar is furthe distinguished from fruit or grape-sugar by it pure and powerful sweetness, and the facilit with which it crystallizes. Grape sugar is ver inferior in sweetness; it crystallizes imperfectly and is usually obtained in a granular state. I is accompanied in fruits by malic, citric, or tar taric acid. It may be produced artificially b the action of various agents on cane-sugar, an also upon lignin, starch, and gum. It forms th solid crystalline portion of *honey*; it also occur in urine in the disease called *diabetes*. The term sugar has also been applied to *manna* or *man nite*, which occurs in the juice of some kinds o ash, in orchard trees, in celery, &c.: this kin of sugar, however, does not ferment. The juic of the *liquorice* root, and a few other substances are also classed under sugar.

Cane-sugar.—Cane-sugar, when pure, is whit and brittle: it becomes phosphorescent by fric tion, and a lump, on being broken, emits a electric spark which is visible in the dark. It density is about 1·6. It dissolves in about one third of its weight of cold water, but in a muc smaller quantity of boiling water. The *syrup* thus formed is viscid, and on being evaporate at a moderate heat, deposits fine crystals o *sugar candy*, of which the usual crystalline form is a six-sided prism commonly flattened and ter minated irregularly. The crystals are said t consist of 100 parts sugar, and 5·6 parts o water. A solution, saturated at 230°, forms i cooling a granular mass or *tablet*, but when th solution is rapidly boiled down until it acquire a tendency to vitreous fracture on cooling, o when fused at about 280°, or until a portion *feathers* or concretes on being thrown off from stirrer, it may be poured out upon a marble o

metal slab, and will form a transparent amorphous mass on cooling. This vitreous mass was formerly obtained by rapidly boiling down a concentrated solution of sugar in barley-water or sweet-wort, and hence the name of *barley-sugar* applied to sticks of it formed by cutting the amorphous mass while hot into strips, rolling the strips into cylinders. and then giving a spiral twist to the cylinders. In this state the sugar is vitreous and transparent, but after some time especially if exposed to air, it crystallizes, acquires a fibrous or granular texture, becomes opaque first on the surface, and then throughout the mass. Confectioners add a small quantity of vinegar or tartaric acid to the sugar which retards this tendency to opacity. The show-sticks which are kept in the windows of grocers &c. are made of coloured glass very accurately resembling the barley-sugar in its freshest and most transparent state. The tendency to crystalize is also removed by keeping the syrup for a long time at a temperature near its boiling point ; but in such case a portion of the sugar probably passes into glucose.

The cultivator distinguishes 3 species of canes. 1. The *Oreole* cane, which has dark green leaves, and a thin but very knotty, stem ; it is indigenous to India, and was transplanted thence to Sicily, the Canary Isles, the Antilles, and to South America. 2. The *Batavia*, or *striped* cane, which has a dense foliage, and is covered with purple strips ; it is chiefly cultivated in Java for the manufacture of rum. 3. The *Otaheite* cane grows most luxuriantly : it is the most juicy, and yields the largest product. This variety is chiefly cultivated in the West Indies and South America. It becomes ripe enough for the mill at 10 months, and is more hardy than the other varieties. The sugar cane being originally a bog plant, requires a moist nutritive soil, and a hot, tropical, or subtropical climate. It is propagated by slips or pieces of the stem with buds on them, and about 2 feet long. It takes from 12 to 16 months, according to the temperature, before it arives at maturity. Towards the flowering season the leaves fall off, and the stem acquires a straw-yellow colour. Some planters cut the cane before the flowering season, but generally some weeks after. The plantations are so arranged that the various divisions of the fields may ripen in succession. The land should be well supplied with manure rich in nitrogen, but not containing much saline matter.

A beet-root factory established at Naples, near the sea-shore, experienced heavy losses in consequence of employing beet-roots grown in the neighbouring fields ; and we have also heard of similar losses in a German factory from the use of beet grown in a field in front of the graduation-house of the salt works at Manheim. A similar effect has been observed with respect to sugar-cane. Those which are grown near the sea make an inferior sugar to those grown inland ; the quantity of melasses is greater, and the sugar more deliquescent. Mr. Kerr states, [A Practical Treatise on the Cultivation on the Sugar cane and the Manufacture of Sugar, by Thomas Kerr, Planter, Antigua, London, 1851.] that on the windward coast of Barbadoes he has tasted melasses as salt if it had been mixed with strong brine. After the harvest the roots strike again and produce a fresh crop of canes ; but in about six years they require to be removed. The time for cutting the canes varies with the soil and season, and the different varieties of the cane. The usual signs of maturity are a dry, smooth, brittle skin; a heavy cane ; a grey pith, approaching to brown ; sweet and glutinous juice. The canes should be cut in dry weather, or the juice will be diluted with an excess of water. The development of the buds which form the secondary stole of a plant that has been cut, are named *rattoons*, and they are *first*, *second*, or *third*, &c., according to the age of the root which produces them. They diminish every year in length of joint and circumference, and although they have not the handsome appearance of the original plant they yield much richer juice and produce finer sugar. The juice from the rattoons is also said to be more readily clarified than that from the plant cane. The canes should be cut as close to the stole as possible, in order to give vigour to the rattoons that are to spring from the old root : besides this, the juice of the lower joints is the richest in the cane. The cane-top, with one joint of the cane, or two joints if not quite ripe, must also be cut off. The canes are tied up in bundles, and conveyed to the crushing mill, particular attention being paid that the supply does not exceed the demand, otherwise the cut canes would ferment and spoil. Mr. Kerr recommends that the land should be deeply ploughed and thoroughly pulverized ; that cultivation should no longer be carried on by hand, but with implements, as in the best farming in England; and in putting in a plea for the better treatment of the cattle, he reminds the planter that the Psalmist, in praying for the prosperity of his people, asks emphatically, among other blessings, that " our oxen may be strong to labour, that there be no decay." Mr. Kerr states, that it is usual to plant the canes in parallel rows 6 feet apart, and the canes 4 feet from each other in the row. He recommends wider spaces, such as eight feet between the rows ; and states that in Barbadoes, in 1847, 90 acres of cane, planted 8 feet by 4 yielded 230 hogsheads of sugar. Some have even recommended to increase the distance to 10 feet, and others have advocated 8 feet square : that is, the canes in rows 8 feet apart and 8 feet distant from each other. It is also advisable to extend the planting over a period of 5 months ; to begin early, so as to finish before the rainy season sets

in. In addition also to the many advantages of returning the cane-trash to the land, Mr. Kerr states, that by spreading it over the spaces between the cane rows, it prevents the disastrous effects of severe droughts. The cheap rate at which coals can be sent from Great Britain to the colonies makes it desirable to abandon the use of cane-trash as fuel. The juice of the sugar-cane consists of a nearly pure solution of sugar in water, with traces of albumen, about $\frac{7}{100}$ of gum and a peculiar substance resembling gluten or vegetable gelatine, which is deposited in large quantities in the vats in which sugar is fermented for making rum. The juice also contains of cerosin and a green vegetable wax, about $\frac{3}{100}$ to $\frac{4}{100}$. The mineral ingredients are similar to those in other plants and vegetable juices, and consist of the sulphates of lime, and potash, chlorides of potassium and sodium, phosphate of lime, silica &c. The juice is sometimes colourless, but generally yellow : it is made turbid by the presence of greyish globules of suspended matter. Its taste is agreeable, but rather insipid, and it has a peculiar balsamic odour. After the cane has been passed through the rollers and as much of its juice squeezed out as this imperfect method admits of, it is called *cane straw*, *bagasse* or *cane-trash*. It consists of—

It is important to observe, that while the chemist has proved that as much as from 17 to 20 per cent. of crystalline cane-sugar exists in the cane or fresh juice, the sugar-boiler in the colonies does not obtain more than 7½ per cent., or less than one-half. His object is to convert the juice as speedily and with as few operations as possible into raw sugar ; hence he has not been very active in improving on the old method of manufacture, which entails loss or deterioration of juice at every stage of the process : there is first a large loss in consequence of the imperfect method of expressing the juice from the cane, and, secondly, a chemical change in consequence of long exposure to the atmosphere at

ordinary as well as at high temperatures, whereby the crystalline sugar becomes degraded into mucilaginous or non-crystalline sugar, commonly called *molasses* or *treacle*. The juice of the cane is purer, and contains twice as much sugar as that of beet-root, and yet the manufacturer of beet-root sugar manages, by means of improved processes and apparatus, to make the beet-root juice as productive as cane juice. It is true that the planter labours under certain disadvantages which may not be altogether compensated by a richer juice ; the sugar cane contains 2 or 3 times as much woody fibre as the beet, which is soft and full of cells, while the cane is fibrous and spongy, and is surrounded by a hard integument difficult to submit to pressure. Moreover in the climate of the sugar cane the ordinary temperature of the air is highly favourable to fermentation, so that the danger of decomposition is greater than in the case of the beet. The fact, however, still remains, that while science has been actively employed in perfecting the manufacture of beet-root sugar, she has, until recently, done little or nothing for the manufacture of cane-sugar ; and now that attention had been fairly directed to the subject, in consequence of the depressed condition of our colonies, much of the beet-root apparatus is found to be admirably adapted to the wants of the colonial sugar boiler. The original crushing apparatus of India was a kind of squeezing mortar, made out of the hollow trunk of a tamarind-tree, worked by a yoke of oxen, the pestle or stamper being a strong beam, 18 feet long, and rounded at the bottom so as to squeeze or crush the canes in the mortar. Squeezing mills, similar to those used for expressing oils from seeds, were also used. There were also other forms of apparatus before rollers were introduced. Rollers of stone or iron were first used with the axes in a vertical position ; but the horizontal was soon found to be more convenient and economical. The scarcity of fuel is so great in some of the colonies, that it has even been purposed, instead of expressing the sugar-cane, to cut it in slices to dry them, and send them to Europe for manufacture into raw or refined sugar. But the very defect of fuel which led to this proposition would evidently be the chief barrier to carrying it out, since the fuel required for drying the canes would be wanting. The true remedy for the enormous waste that attends the present mode of manufacturing raw sugar, must be found in the application of a regulated steam heat with coals for fuel, while the cane trash shall be left to its more legitimate application of manuring the land for future crops. The waste of sugar by the old process has attracted the notice of French as well as English writers. Thus Dumas states that of the 84 to 90 per cent of juice in the fresh cane, only from ⅔ds to ¾ths are obtained from the presses : that this ⅓ds contain only 12 per cent.

of the sugar actually existing in the fresh cane, 6 per cent. being left in the trash which is used as fuel : so that for every 80 milions of kilogrammes of raw sugar imported into France, 40 millions of kilogrammes have been burnt in producing them; the value of which, about 20 millions of francs, is actually thrown into the fire.

Clarification or *defecation* of the juice is produced by heat, which coagulates the albumen, and by the addition of lime, which neutralizes the acid, and renders some of the solid impurities insoluble. By the old method an arrangement called the *copper wall*, consisting of 5 pans, iron boilers, or *teaches*, as they are called, walled together in a row, and heated by one common fire, are used for the purpose. From the juice reservoir, below the crushing mill, the juice is conducted into the clarifying pan, the fifth in the row, the largest, and farthest from the fire. It should be capable of holding the whole of the juice produced at one crushing, and should be ready to receive the juice almost as quickly as it is expressed. In some cases two copper walls are built under the same shed. The proper dose of milk of lime, or *temper*, as it is called, should be measured out by means of a vessel graduated into inches, each inch corresponding to $4\frac{1}{2}$ oz. of milk of lime. Not less than 5, or more than 10 oz. are required to clarify 1,800 litres, or about $\frac{1}{1000}$ to $\frac{3}{1000}$ the entire weight of juice. When the proper temperature has been acquired, 10 litres of juice yield 15 grammes of precipitate, containing,

Gum resembling cherry gum	50.25
Green matter (chlorophill)	10.05
Albumen, with particles of wood fibre	22.78
Phosphate of lime	3.35
Silica	14.07
	100.60

The phosphoric acid is originally present in the form of an acid salt ; hence if copper vessels be used in clarifying, the metal is soon attacked and phosphate of copper formed : the lime converts this salt into a basic phosphate, which combines with silica and organic matters, and materially assists the precipitation of foreign ingredients. A dense impure scum collects on the surface, and is removed by skimming. The juice is then passed through the other 4 teaches, and heated until the evaporation is complete. During this process a large quantity of thick scum is removed by means of a perforated copper plate attached to a handle. The formation of this scum is a striking illustration of the defects of the system, for the scum consists of nearly pure sugar, decomposed by heat, together with the natural impurities of the juice : it is passed into the melasses cistern, and is chiefly used for making rum. As the bulk of juice is diminished by evaporation, so the teaches are usually made to diminish in size, the juice being passed from one to the other by a copper ladle or dipper worked by hand. The sugar is greatly injured by this repeated ladling and exposure in small quantities, to the atmospheric air, and indeed the whole plan justifies the satirical remark, that it is "an elaborate and effectual means of converting pure sugar into melasses and scum." And Mr. Kerr remarks, that "the whole system, from the breaking up of the first clod of earth, to the rolling of the hogshead of sugar into the waggon, appears to have been expressly contrived for employing the greatest possible amount of labour." When most of the scum has been removed in a compact form from the clarifier, the juice is ladled to the next pan, and as it diminishes in volume fresh juice is added. The pans are in some cases on different levels, so that the juice may be drawn off from one into the next below it, by means of a syphon ; but the pans are not usually terraced, so that the juice has to be scooped from pan to pan. In the second pan the concentration begins ; the boiling liquor throws up a scum, which the negroes collect and return to the clarifying vessel. In the last pan but one the juice is concentrated to 30° Baume, and it is then passed into the last and smallest pan, which is situated directly over the fire. Here the boiling is tumultuous, in consequence of the formation of *panstone*, a deposit of lime consisting of—

Basic sulphate of lime	92·43
Carbonate of lime	1·35
Silica	4·70
Phosphate of copper	1·41
	99·89

with organic matter. The panstone forms more or less in all the boiling operations : it causes the juice often to be over-heated, the sugar to be burnt, and caramel to be formed, as when the incrustation cracks and the juice comes in contact with the hot metal. The crust is from time to time removed by heating the empty pan to redness, when, in consequence of the greater expansion of the metal, the crust breaks up and peels off. Sometimes the last and smallest copper contains a *skipping-teach*, a smaller vessel of the same shape, with a valve at the bottom worked by a handle. This vessel is let down by a crane into the pan, removes the sugar from it and conveys it to the coolers. In some cases, the concentrated syrup is discharged down shoots into the coolers. Sometimes the term *teache*, or *tayche*, is applied only to this last vessel, in which the syrup is reduced to the *granulating* point, or sufficiently concentrated to separate on cooling into grains of sugar. The required consistency is ascertained by taking a small portion of the syrup upon the thumb, then bringing the forefinger in contact with it, and again separating them, noting the length to which a thread of syrup can be drawn before it breaks ; if it ex-

tend to about half an inch in length, the sugar is judged to be fully boiled. This trial by the *touch* is supposed to have given the name of *teache* to the pan. The coolers are shallow open vessels, each capable of containing about a hogshead of sugar. They are of wood, with thick sides, that the cooling may be gradual. In about 24 hours the sugar grains, or forms, into a soft mass of crystals, imbedded in melasses, which are separated in the *curing-house*, to which the soft sugar is removed. The sugar in the coolers is frequently stirred with iron rods, to produce a uniform temperature and consistency. The curing-house is a large building, the lower part of which is lined with lead, forming the melasses' reservoir. Over this, on an open framing, are placed the hogsheads or *potting-casks*. In the bottom of each cask are bored several holes an inch in diameter, into each of which is placed a plantain stalk, or a crushed cane, of sufficient length to reach to the top of the hogshead. The soft sugar being placed in these casks, the melasses gradually drain away through the spongy stalks or canes, leaving the crystalline portion tolerably dry. In 2 or 3 weeks, or 5 or 6 if the mass be mucilaginous and the grain small, it is fit for shipment; a further drainage of melasses takes place in the hold of the vessel, and even after this there are melasses entangled with the crystals of the raw sugar, to the injury of its quality. Such is *raw* sugar of commerce: it varies greatly in quality, but really consists of a crystalline flour of pure sugar, moistened throughout with melasses, often to the extent of one-third of its weight, and often more than the crystals can contain. Hence as it attracts moisture from the damp air of the vessel and becomes more liquid, it escapes from the crevices of the casks. It is calculated that about 12 per cent. of sugar is lost in this way from the English colonies alone, or about 27,000 tons annually. In places where the sugar is not packed in hogsheads for the sea voyage, it is set to drain in the curing house, in wooden moulds of deal. The syrup which drops from the moulds, or from the hogshead, into a cistern, deposits on cooling a sugar, the grain of which resembles fine sand, and forming a layer on the bottom several inches in thickness. This inferior product is called by the French planters, *fond de cisterne*. It averages about 10 per cent. of the raw sugar, depending on the temperature at which the sugar is placed in the moulds. It has a moist and smeary character, and is an admixture of various salts, of gelatinous silica, mucous or gum deposited from the refuse syrup, or mother-liquor, of the first crop of crystals. The defects of the old system most plainly appear from the various modes adopted for calculating the loss. We have already given one or two estimates, and will conclude this section with one or two more. From every 1,000 parts of sugar-cane the old process yields from 60 to 80 parts raw sugar, and 25 to 30 of melasses; while according to chemical analysis the yield should be 180 to 200 parts of crystallized sugar. The following table has been drawn up from a large number of comparative results:—

In 1,000 parts—		
Raw Sugar	79	73
Melasses	30	27
Trash	386	395
Water	505	505

Thus of the 180 to 200 parts of crystalline sugar in 1,000 parts of cane, there are obtained from 73 to 79 parts of raw sugar: 18 to 20 parts of melasses; cane trash, 28 to 33; and waste in the process of manufacture, from 48 to 61 parts. Mr. Kerr also states that of the 1,500 gallons of juice required to make a hogshead of sugar netting 15 cwt. in the English market, the planter does not get a return of more than 6 per cent. of moist muscovado sugar, and that of very inferior quality.

Improved System of Manufacturing Raw Sugar.—The various improvements in the rude process of manufacturing sugar described in the last section have for their objects the preservation of the juice from fermentation, and its concentration with as little agitation and exposure to the air, and at as low a temperature as possible. Several proposals have been made for removing or diminishing the causes which lead to the rapid fermentation of the juice. Among other plans, Dr. Mitchell proposed to destroy the vitality of the glutinous fermenting matter, and to coagulate the albuminous substance in the tissue of the cane, by plunging the canes into some boiling liquid as soon as possible after they are cut. This plan would prevent the albumen, &c., from passing into the juice by expression. From some experiments made on this subject, it appears that a colourless juice was obtained: it was full of floating feculæ which immediately subsided, and the juice being decanted off and boiled down without the addition of any lime or temper, or any necessity for skimming, furnished a pure white sugar. By this process, the juice is diminished in quantity, but increased in density. Some of it was kept for 18 hours without undergoing any change. M. Payen recommends the use of sulphurous acid or of bisulphite of lime for preventing the rapid fermentation of the juice. He advises that the ends of the canes be dipped into a solution of the bisulphite as soon as they are cut. An infusion of tannin or nut-galls has also been recommended for the separation of the diliquescent matter and soluble salts. As the crushing-mill is generally on the ground, the juice is raised to the clarifying vessels by force-pumps of peculiar construction, and with very little agitation. For this purpose it

is admitted into an apparatus called a *monte-jus*, from which it is forced up a pipe by the pressure of steam on the surface of the liquor where is a vessel for receiving the juice, which passes into it by a pipe for supplying steam for forcing the juice up. There is an air-cock, through which the air escapes on the admission of the juice: the pipe attached to this cock dips 2 or 3 inches below the top of the cylinder, so that the juice never rises above that height: the space above being filled with air, acts as a cushion between the steam and the cane-juice, thereby preventing the juice from being heated to the temperature of the steam. The pipe is not only continued to the bottom of the receiving vessel, but dips into a sunken receptacle, by which means all the juice is collected; for it is of importance not to leave layers of juice at the bottom of vessels to ferment and damage the fresh juice afterwards added. Steam-heat is used for the clarifying vessel, into which the juice is raised by the monte-jus. This vessel consists of a hemispherical copper pan surrounded by a cast-iron jacket, and steam is admitted into the space between the two, the supply being regulated by a valve. On the top of the copper pan is fixed a *light course* or copper band, from 15 to 18 inches deep, to prevent the scum from frothing over. The plug in the bottom of the pan is furnished with two or three holes, through one of which clarified juice passes down the hollow of the plug to the smaller channel of the two-way cock. When the clear liquor is run off, the plug is removed by the means of the handle and the thick scum and sediment pass off through the larger way. The condensed steam passes away by a pipe and there is a cock which is opened for a short time on the admission of steam, to allow the air to escape. The clarifier being filled with juice, steam is admitted and the temperature raised to 176° Fahr. Any particles which rise to the top of the liquor are skimmed off, and milk of lime is poured in in quantities just sufficient to neutralize the acid, which is ascertained by the frequent use of litmus paper. The heat is continued until there is formed a thickness of 3 or 4 inches of scum, consisting of most of the impurities of the juice. In about 10 or 12 minutes from the first application of heat the scum should be well formed and about to break up. The moment it begins to crack the steam is shut off, and the liquor being left for 15 to 20 minutes, the lighter impurities will have mostly risen to the surface, and the heavier ones sunk to the bottom, while between the two is a pale and beautifully clear liquor. The hollow plug which is ground into the hole in the bottom of the pan, is now turned by its long handle so as to throw open a hole in the side 3 or 4 inches from the bottom, and consequently above the subsided impurities: by this opening the clear liquor escapes and proceeds along the small channel of the two-way cock until scum begins to appear; the cock is then turned on to the larger way, the plug is altogether removed, and the heavy matters and scum pass out through the hole, and are conveyed to a cistern, placed in bags, and the juice squeezed out. The juice in the clarifier is never allowed to rise above 208° or 209°, or the impurities would become so mixed up with the juice as to be incapable of separation; a result which will also be attained unless the process be speedily conducted. The clarified juice still contains matters in suspension, which require to be removed by filtration. The filters consist of fine copper-wire sieves in sets of 4 or more each, the one above fitting into the one below, the mesh of the lower sieves increasing in fineness. In filling in the bone-black, the first few inches are pressed compactly down; after which it is filled lightly, but evenly, to within a short distance of the top, where a space is left for the accumulation of the cane juice. In the charcoal filters used in France, upon the false perforated bottom a filter-cloth is spread, and upon this the charcoal is placed, first in well packed layers, and afterwards a little more loosely. Another cloth is placed on the top, and upon that a perforated plate of metal. The syrup to be filtered is let in from the cistern and the supply is regulated by a ball-cock, a certain quantity being always kept at the top of the filter to prevent the charcoal from drying and dividing into vertical channels or cracks, and forming what the French call *de fausse voies*. To allow the syrup to accumulate in the bottom reservoir of the filter, it is necessary to let the air escape, for which purpose a tube is provided. There is a man-hole for cleaning out the filter when required. The object of filtering is to remove all vegetable colouring matter and any excess of lime that may have been accidentally added in the clarification, together with mineral salts, such as sulphate of lime, originally present in the juice. About 5 tons of animal charcoal are required for every 100 tons of sugar made. After this the charcoal is reburnt, and thus its useful properties are restored to it. When filtered liquor is ready for evaporation, according to the improved processes, it may be conducted either in the *vacuum-pan* or in open pans, containing a coil of steam-pipe. The usual plan is to concentrate the liquor in open pans to the density of 25° to 28° Baumé, up to which point it is not greatly acted on by the atmosphere. The evaporators used for this purpose are large iron vessels, with copper pipes at the bottom bent round, the extremities of which terminate in a straight gun-metal tube passing through stuffing-boxes: the pipe, which conveys the steam, is at one end of the straight tube, and the pipe which discharges the condensed water at the other. By this arrangement the pipes

can be raised up out of the vessel for the purpose of cleaning it thoroughly; for if the cane juice be allowed to hang about the pipes, it will become acid and infect the next charge. By means of a lever the evaporator can be tilted into a sloping position for the purpose of better running off the evaporated juice by the cock. In these vessels the juice is evaporated to about 27° B. before going into the vacuum-pan. The drainings are collected in pots or treacle-jars which support the moulds, and are boiled down with other refuse of the sugar-houses into an inferior sugar. A separate pot for each mould is not to be commended, for if the pots are not well washed out there is a liability to fermentation, or *smear*, as it is called, and this will spread through the whole establishment with astonishing rapidity, and when once formed is difficult to eradicate. We have heard of a sugar-refiner who had to work up the whole of his stock twice before this evil could be got rid of. The use of pots is, in many cases, superseded by supporting the moulds in frames, and allowing them to drain into gutters or false floors of thin sheet-copper, sloping towards a centre constructed under the main floor, where the syrup is conveyed by copper pipes to a cistern. It has been proposed to expedite the draining of the moulds by connecting their nozzles with a pipe communicating with an air-pump; but in such an arrangement the sugar would be liable to be drawn through the perforations with the syrup. Several other plans on the vacuum principle have also been proposed. When the sugar is properly drained it is taken out of the moulds in the form of loaves, which are trimmed to shape, placed in a stove or hot room of the temperature of 130° to 130,° and when the moisture has evaporated, they are fit for the market. The sugar thus obtained is half the weight of that let down into the heater from the vacuum-pan: the remainder consisting of moisture or drainings. A very small proportion of the syrup that drains away consists of uncrystallizable sugar or treacle in which all the impurities of the loaf are accumulated. If the improved operations have been well conducted the produce is equal to refined sugar, and there is no practical reason why perfectly white sugar should not be produced from the canes at one operation. The sugar, as it comes direct from the canes, contains only 1·5 per cent. of impurities, whereas the sugar-refiners in England have to operate on a material considerably deteriorated by previous mismanagement. Fiscal regulations have hitherto interfered with colonial improvement, a larger duty having been imposed on sugar above a certain standard, thus actually discouraging the production of white sugar at its natural seat of manufacture, and encouraging slovenly and bad work. In the islands of Java and Cuba, where the best machinery has been introduced, from 30 to 40 per cent. is now saved in the quantity of sugar produced, and its market value is increased from 5*s*. to 10*s*. per cwt. The manufacture of *sugar-candy* may be regarded as a branch of the refiner's art. The large crystals of sugar, which pass by this name, are prepared from a syrup clarified with a less quantity of charcoal-powder than is usual, and not passed through the filter. The crystals, which are coloured, inclose a certain portion of non-crystalline sugar. If the candy is required for the sake of its solvent action on the mucous membrane of the throat, it should not be prepared from clarified or clayed sugar. To increase its mucilaginous and sticky properties it should, after clarification with white of egg, be boiled over an open fire and not in vacuo; and for the darker kinds of sugar-candy a higher temperature should be employed than for the lighter. The syrup is set to crystallize in a copper vessel with smooth sides, and contracted towards the bottom that the crystals may be easily removed. At the sides are several small rows of holes at equal heights, through which strings are passed which serve as nuclei to the crystals. The copper is filled up above the strings, and is then placed in a drying chamber at the temperature of from 104° to 122°. As the syrup cools and evaporates, solid crystals are slowly formed, partly on the surface, but chiefly on the strings and the sides. The crystals on the surface are frequently broken up. In 6 or 8 days the crystallization is complete; the vessel is inverted, the syrup drains off, and when the dropping ceases the crystals are removed and dried.

Palm Sugars.—The various kinds of palms contain in their stems a juice charged with cane-sugar, which, in the fresh state, is named *toddy*, in India, and when fermented and distilled, *arrack*; it is by the evaporation of toddy that the sugar termed *jaggery* is obtained.—*See pages* 1771 and 1772.

The process from one of the palms, the cocoanut is thus described: a man named a "toddy-drawer" ascends the tree, cuts off the point of the spadix, and passes a ligature firmly round the stump. It is then beaten with a stick, which is supposed to determine the sap to the wounded part. The process is repeated for several days, a small portion of the end of the spadix being cut off each day. The juice soon begins to flow from the cut surface of the flower, and is carefully collected in an earthenware vessel suspended from the spathe. A thin portion of the flower and spathe is sliced off daily, and the end of the stump is bound with a ligature. A good healthy blossom will give from 2 to 4 pints English of sweet juice or *suri* daily, and some flowers will continue to yield juice for 4 or 5 weeks. There are frequently 2 spathes on one tree yielding suri at the same time, which by exposure to the air immediately begins to ferment, and forms the intoxicating liquor, *toddy*. By distillation,

this juice yields about one-eighth part of arrack, of the same strength as good brandy. The seamen belonging to the Royal Navy in the Indian Seas, are furnished with it instead of rum. By allowing the juice to pass into the acetous fermentation, an excellent vinegar is obtained, in which a great variety of vegetables are pickled. Suri is the yeast commonly used by the bakers in Ceylon. In order to obtain sugar (*jaggery*) from suri instead of spirit, great care must be taken to prevent fermentation. The earthenware pot in which it falls is emptied twice or thrice in the course of 24 hours, and is well cleaned and dried each time; a small quantity of lime is then thrown into it: the juice is filtered through the reticulated substance at the base of the leaf, and then slowly boiled in an earthenware vessel until it becomes light coloured and viscid. While still warm and semifluid, it is poured into sections of coco-nut shells, where it soon becomes solid. A gallon of juice yields about a pound of sugar. Jaggery contains both the crystallizable portion of the juice, and a quantity of molasses or liquid sugar; but they are separated by a subsequent operation. This coarse sugar is usually made into small loaves of the shape of a hemispherical vase from the form of the vessel in which it cools. It has a deep chocolate colour, and when broken presents many clear particles of sugar. In the Malay language, jagery is called *goola* or *goora itan*, black sugar or black sweet. Jaggery is sold at the rate of about 2*d*. per pound. The Ryots, or peasants dependent on the land-owners in the East Indies, also cultivate the sugar-cane, express the juice, and boil it down to a thick syrup: they then transfer it to the Goldars, who produce the solid sugar. The crude syrup is named *goor*, and is of various qualities, one of which, in common use, is also called by the English settlers *jaggery*. There is an association of farmers, who convert the syrup and send the produce of each man's land to a common manufactory. Jaggery is sometimes adulterated with earth and sand. The colonists of Ceylon and India prepare refined sugar from jaggery: it is of a yellowish white colour: it is known in the English market under the name of *date-sugar*. A similar product from Africa is known as *date-sugar of Mogador* (the port of Morocco). See TODDY.

Manufacture of Rum.—The refuse of the sugar-cane is chiefly employed in the manufacture of rum The melasses, the skimmings from the clarifying and evaporatiug coppers, and even raw cane-juice diluted with water, are all used for this purpose; *dunder*, or the wash of former operations, deprived of its alcohol by distillation, being used as a ferment. The fermentation is complete in from 5 to 7 days, and the liquor must be transferred to the still before the acetous fermentation shall have set in. A small portion of lime or of solid limestone is added to correct any acidity that may have formed. The spirit is allowed to flow through the worm until it is no longer inflammable. It is then rectified in a smaller still. Mr. Wray states that 1,200 gallons of wash yield 113 gallons of proof rum. Rum is coloured by means of caramel. Mr. Wray lays great stress on the action of the dunder. He terms it the aromatic substance which modifies the changes or transformations which take place during fermentation, that it increases the density of the liquor, and prevents violent fermentation; that good dunder should be light, clear, slightly bitter, and quite free from acidity; and that its action is similar to hops in diminishing the influence of decomposing azotised bodies, which is to convert alcohol into acetic acid.—*Tomlinson.*

Sugar, its impurities and adulterations.—As already noticed, two kinds of sugar have been particularly distinguished by chemists, viz., cane and grape sugar or glucose. The first is obtained from the sugar-cane, the beet-root, the maple tree and some other plants, while the second is contained in greater or less quantities in most fruits, and particularly in grapes and figs. Honey, although usually described as consisting of grape-sugar, contains a large quantity of crystallisable sugar resembling cane-sugar, and is therefore probably a mixture of two kinds. These two sugars differ considerably in many of their properties. Cane sugar consists of oxygen, hydrogen and carbon, in definite proportions; it is crystallisable, the crystals are six sided oblique prisms, and when pure, not prone to deliquesce, or alter when exposed to moisture or a moderate temperature.

Grape sugar consists of the same elements, but contains a less proportion of carbon. Unlike cane-sugar its manufacture can be effected by art, that is by the action of the dilute mineral acids, particularly the sulphuric, on either starch or woody fibre: it has but little disposition to crystallise and when it does so the crystals assume no definite figure but are arranged in acicular tufts; exposed to moisture or a moderate temperature it readily deliquesces.

Pure and unadulterated cane-sugar, should present a highly crystalline texture; should be of light colour and free from clamminess or moisture. These two sugars may be readily discriminated from each other by the action of certain tests and grape-sugar particularly by the copper and potassa tests. Now grape-sugar is frequently introduced for the purpose of adulteration.

On Vegetable Albumen in Cane-Sugar—Vegetables, like animals contain principles into the composition of which nitrogen largely enters: the chief of those is vegetable albumen.

Substances entirely different from sugar in their nature are but seldom employed in the adulteration of that commodity. The grocers having recourse to proceedings more

natural and more difficult of detection, but scarcely less dishonest, than the introduction of foreign matters possessed of wholly different properties. The Mixing or Handling of sugar, consists in the mixing together, in various proportions, of sugars of different qualities and prices, none of which are very pure, and some highly impure: an article is thus prepared, presenting a tolerable appearance to the eye, but which is really one of very great impurity, and rarely what it professes to be, "real Jamaica," or "Demarara sugar," &c.

The impure sugars are dark-colored; imperfectly crystallised, heavy, and clammy, readily caking into masses: examined with the microscope they are found to contain fragments of cane, woody fibre, grit &c., and to abound with the acari and sporules of fungus. The raw or Muscovado sugar of the West Indies is of this nature, as well as, indeed, to a less extent nearly all the brown sugars imported into Great Britain. Now these inferior sugars are largely employed to mix with the whiter and drier sugars of the East Indies and the Mauritius, and are thus sold to the public.

Blood in sugar.—The employment of the blood of animals is confined to the manufacture of loaf sugar—but its use, we believe, is now very frequently dispensed with, even in the preparation of this article. The blood acts only through the albumen which it contains. One of the great difficulties of sugar-refining arose from the presence of vegetable albumen in the cane-juice, and here we have the apparent contradiction involved in the practice of putting albumen into the solution of sugar. The advantages derived from the use of this substance, we presume, are considered to more than counterbalance the disadvantages attending it and indeed it would appear that there is not the same difficulty in the removal of animal albumen as is experienced in the abstraction of vegetable albumen. The mode of its operation is as follows: the fluid albumen is diffused throughout the whole of the sugar solution to be clarified; on the application of heat the albumen immediately solidifies, and forms meshes and films, which being lighter than the water, ascend, and in their upward course carry with them the solid impurities contained in the solution, on the surface of which a scum is gradually formed, consisting of the impurities in question and the solidified albumen this scum may be removed by skimming. Now, as it is the albumen of the blood only which assists in clarifying the sugar-solution, and not the blood itself, it would be far better that albumen alone, as white of egg, should in all cases be employed. Blood is a fluid compounded of fibrin, albumen and a variety of salts and effete substances, its use, therefore, in the manufacture of lump sugar, is not merely disgusting, but is calculated to prove injurious to the health.

Acarus sacchari, or *sugar Insect.*—There is very commonly present in the more impure kinds of sugar, a beetle-like animalcule, of the genus Acarus.

The discovery of the very general presence of this acarus rests we believe entirely with Dr. Hassall. The sugar acarus approaches somewhat, in organisation and habits, the louse and the itch insect itself which are also included in the genus Acarus The sugar mite is in size so considerable that it is plainly visible to the unaided sight. When present in sugar, it may always be detected by the following proceeding: two or three drachms or tea-spoonfuls of sugar should be dissolved in a large wine-glass of tepid water, and the solution allowed to remain at rest for an hour or so, at the end of that time, the animalcules will be found some on the surface of the liquid, some adhering to the sides of the glass, and others at the bottom mixed up with the copious and dark sediment, formed of fragments of cane, woody fibre, grit, dirt, and starch granules, which usually subsides on the solution of even a small quantity of sugar in water. We will now proceed to give a description of the acarus in question and observe in the first place that the whole of its development may be clearly traced out in almost every sample of brown sugar. The *Acarus sacchari* is first visible as a rounded body, or egg; this gradually enlarges and becomes elongated and cylindrical until it is about twice as long as broad; after a time, from the sides, and one extremity of this ovum, the legs and proboscis begin to protrude. The acarus thus far formed goes on increasing in size until it attains its full growth, when it is visible to the naked eye as a mere *speck*. Dr. Hassal gave the following, as the results of his Microscopical and Chemical Analyses of samples of Brown sugars, the produce of the different countries, noted below.

Madras.—Sugar dark, moist, staining the paper; somewhat crystalline, crystals small: contains fragments of cane; several acari, very few starch granules; grit, much grape-sugar and vegetable albumen.

Madras.—Contains a few pieces of cane; starch granules, much grit; several acari and ova; grape-sugar; albumen.

Mauritius.—Contains much cane; ten or twelve acari, of large size, several ova of same; a few starch granules; fragments of woody fibre; grit; much grape-sugar and albumen.

Mauritius.—Contains some cane; several acari, a few starch granules—those of arrowroot; grit; grape sugar and albumen.

Calcutta.—Sugar not very dark, dry, earthy looking, but few crystals apparent, and those very

small not much cane; a few starch granules; no acari visible, grape sugar; albumen.

...ta.—Sugar perfectly white, dry, and crystalline, resembling crushed lump, a few granules, no acari, fungus, cane, or scarcely a trace of grape-sugar or albumen.

Bombay.—Sugar exceding dark-colored, earthy damp, contains some cane; a great many starch granules: (sago ?) numerous acari; much grape-sugar; albumen.

Cassipore, Calcutta.—Sugar pale straw-colour, dry and highly crystalline, large-grained, a very few species of cane, one small acarus, a few starch granules; scarcely a trace of albumen or grape-sugar; a little grit.

Cassipore, Calcutta.—Sugar pale straw colour, not very dry, fine-grained; the crystals being very small contains a few pieces of cane; starch granules, several acari of large size, much grit; a little grape-sugar and albumen.

Jamaica.—Sugar dark-brown not very dry, but still not staining the paper, tolerably large-grained and crystalline; contains much cane; several acari and ova of same, a few starch granules; no grit.

Rio de Janeiro.—Contains much cane, several acari and ova of same; a great many starch granules, like those of Indian corn; much grit; grape-sugar, vegetable albumen. On an attentive consideration of the above eleven analysis... bility... arch of... that only two of the sugars could signed... ded as pure, and in a condition fit is chi... sumption—the white, large grain- side ... gar, resembling crushed lump, and inche... w-colored, large grained, highly Sati... assipore sugar. Of these samples, beau... alcutta was by far the best. It would seem ... vantage if the above described sugars ... oduced in large quantity into logs ... and sold at moderate prices.—*Trassall.*

(7956) SUIDÆ. The Hog tribe. Different Suidæ offer more or less variations in the length of the head. The Wild Boar (Sus Scrofa, Linn.) has the face longer and the skull less elevated; the domestic pig of Europe has the cranium slightly more elevated, and the face still sufficiently long: the Siamese Pig has the face shorter, the cranium more convex in the frontal region and larger in proportion. Dr. J. E. Gray makes the *Suina* a subfamily of the *Elephantidæ*. He includes in it the following species, of which specimens exists in the British Museum:—

Sus fasciatus, the Striped Boar.

S. Scrofa, the Boar.

S. Papuensis, the Bene,

S. Indicus, the Indian Wild Boar.

Babirussa Alfurus, the Babirussa.

Choiropotamus Africanus, the Bosch-Vark.

Phacochærus Æthiopicus, the Valke-Vark, or Emgallo.

P. Æliani, the Haruja, or Hallup.

Dicotyles Tajacu, the Peccary, or Tajacu.

D. labiatus, the Tagnicate.

We now proceed to give some account of the Asiatic forms.

(7957) *Sus Scrofa*, Linn., *S. Aper*, Briss, the Wild Boar, Le Sanglier of the French, The khanzeer, of the Arabs, the Junglie Soor of Hindustan; Dookur, Mah. Adave Pendie, Tel. is still an inhabitant of many of the temperate parts of Europe and Asia, but no longer exists in a natural state in the British Islands,

Dental Formula:—Incisors $\frac{6}{6}$; Canines, $\frac{1-1}{1-1}$; Molars, $\frac{7-7}{7-7} = 44$

The Wild Boar harbours in the most solitary places in retired forests. His lair is generally in some wild and remote spot, not far from water, and commanding by some devious path access to the open country. The young, or Marcassins, as they are termed by the French, the Squeakers of the English in India, are striped with longitudinal bands. Throughout Europe the boar was long held in high estimation as a beast of chase. Nobles, princes and even kings, delighted to take the field with the boar-spear, and peril their persons in hunting this fierce animal. In England where it formerly rioted in the dense forests which have now vanished before the inroads of an increasing population, the loss of his eyes was the punishment inflicted by Willam the Conqueror on him who was convicted of killing a wild boar. In the vast forest which so late as Henry II.'s time stood on the north side of London, were stags, fallow-deer, wild boars, and bulls. In the 'Leges Wallicæ' it appears that Howel-dda gave permission to his grand huntsman to chase the boar from the middle of November to the beginning of December. In Europe, the boar-spear has given way to the rifle; but in India, hunting the wild-boar with the spear is still regarded as the most exciting of all the field sports of the English Officer there, and, perhaps, it is requisite once to see a Bombay Officer descending the tabular trap mountains of the Dekhan, in close pursuit of one of these fierce animals, to know what an Arab Horse and a British rider can do. The hunt of the Wild Boar in Western India, has been made the subject of song, and those alone who have seen or shared their sport can appreciate the proud but well earned exulting with which their poet comrade's song begins, and the consciousness as marked in its close, that the friendships acquired in the

field in youth, will still be vivid in the memory at the decline of life. He sings

The Boar, the mighty Boar's my theme,
Whate'er the wise may say,
My morning thought, my midnight dream,
My hope throughout the day,
Youths daring spirit, manhood's fire,
Firm hand and eagle eye,
Must they require, who dare aspire,
To see the wild boar die,
Then pledge the Boar, the mighty Boar,
Fill high the cup with me,
Here's a health to all who fear no fall,
And the next grey Boar we see.
* * * *
When age hath weakened manhood's fire,
And every nerve unbraced
Those scenes of joy will still be ours,
In memory's tablet traced.
And with those friends whom death hath spared,
When life's wild course has run,
We'll talk of the dangers we have shared,
And the tusches we have won,
Then pledge the Boar the mighty Boar,
Fill high the cup with me,
Here's a health to all who fear no fall,
And the first grey Boar we see.

Throughout India, where the field is taken on horseback, the spear is still used, and hog-hunting is one of the most exciting of all the wild sports of this land of the sun. An attempt was made by Charles I. to restore this noble game to England, and he turned out several wild boars in the New Forest; but the civil wars were no friendly times for the experiment, and they were all destroyed. More recently General Howe procured some wild boars and sows from Germany, and turned them into the forests of Walmer and Alice Holt, or Ayles Holt, "to the great terror of the neighbourhood," as White says, in his 'History of Selborne;' "and, at one time, a wild bull or buffalo: but the country rose upon them, and destroyed them." The senses of the Hog are acute, especially that of smelling. The broad snout ploughs up the herbage; and not a root, an insect, or a worm, escapes the olfactory sense. If fairly treated, it is by no means a dirty animal; but it is too often styed up in its own filth. There are few more pleasing scenes in the farmyard than a well laid-out piggery properly kept. The animal itself is anything but stupid, and is capable of strong attachment where kindness is shown to it. That it is docile the number of learned pigs proves; and still more the famous sporting sow, that went regularly out with the gun, and stood for game as staunch as any pointer. It is said that the Hog is trained on the Continent to hunt for truffles.

(7958) *Babirusa*, F. Cuv.—F. Cuvier has separated this form from *Sus*.

(7959) *Babirussa Alfurus*, the Babirussa, *Sus babirussa* of Linnæus; Le Babyrousa of Buffon; Le sanglier des Indes Orientales of Brisson; and Le Cochon Cerf of Lesson and other French authors. The Babirussa stands high upon its rather slender legs. The skin which is of a grayish colour inclining to fawn colour on the belly, is calthinly furnished with hair. The upper There is come through the skin of the muzzle, impure nearly a circle directed backwards, often of the ing the skin again on their downward curvature. The females are smaller than the males, and are without these tusks. It still inhabits the marshy forests of the island of Bourou, and is said to be abundant in the Moluccas, and a few other islands of the Indian Archipelago. F. Cuvier has given very good figures, and a lively description of two males and females brought to France in the Astrolabe, and kept in the Paris Menagerie. The female was much younger and more active than the male, which was aged and very fat, and spent his short life in eating, drinking, and sleeping. The female bred once after her arrival in Europe. When the male retired to rest she would cover him completely over with litter, and then creep in under the straw to him, so that both were concealed from sight.

(7960) *Sus Papuensis*, the Bene of the natives of New Guinea, is described as being remarkable for its small stature and its agreeable and slender form. The canines of the upper jaw are very small, and nearly of the same form as the incisors; the bristles are rather thick, short, yellow, and brownish below, white above early [illegible]ated with black; the tail is very short wn sugar. [illegible] (Marcassins) are of a brown colo[illegible]e as a rounded deep, with five rather bright fulvo[illegible]larges and bethe back. The length of the P[illegible]til it is about three feet. It is common in the [illegible]ime, from the Guinea, and the Papuans highly es[illegible]vum, the legs which the French found excellent. [illegible]he acanthus thus catch the young in the woods in o[illegible] size until it them in a kind of domestication visible to the remarks that the *S. Papuensis* Dr. Hassal gave of analogy with the Peccaries, a[illegible] of Brown intermediate between them and the True Hogs. —*Eng. Cyc.*

(7961) SUKUR KUND. CONVOLVULUS BATATAS. Sweet Potatoe.

Sukur kund, DUK. | Nutter Aloo, HIND.

A sweet-tasted nutritious root, of which there are two sorts, red and white. The tubers are long, and, when boiled or roasted, very wholesome. They are sown precisely in the same manner as a potatoe, after the hot season, and are fit to be taken up in six months. They sell from two to four pice a seer.—*Riddell.*

Billo...=16), from *Sal*, salt, and *πυξ*, *fire* ...d in medicine by the Greeks, Arabs ...oos. It occurs in some animal sub-...ces, as albumen in Eggs, &c., in some plants, as in Cruciferæ, Umbelliferæ, Garlic, Fungi &c., but chiefly in the Mineral Kingdom ; also combined as in gases or salts, in some minerals and mineral waters. It is frequently found in combination with metals, as in the common ores called Pyrites, the Sulphurets of Iron, of Copper, Lead, Mercury, &c., whence it is obtained by roasting, in England, Germany, Sweden, and at Cuddapah, in this country ; the Sulphur, being volatilized, is collected in chambers. Native or Virgin Sulphur uncombined, is either a volcanic product, or occurs in beds in many parts of the world ; that of commerce is brought chiefly from Italy, Sicily, and the adjacent islands, whence, in 1830, 246,338 cwt. of rough Sulphur were imported. It is afterwards purified by fusion, distillation, and sublimation, hence known under the names of Stick, Roll, Sublimed, and Flowers of Sulphur. Native Sulphur is purified by distilling it from earthen pots arranged in two rows on a large furnace. The Sulphur fuses and sublimes, and passes ...ough a lateral tube in each pot ... on the outside of the furnace, for all fra... ed near the bottom, to allow bility. ...ur to flow into a pail contain- arch of 2... it congeals and forms *rough* or signed a... Native inches ...ound in acute octahedrons, and Satin ... this form, with imperfect octahedral beauti... also occurs massive. The colour seen ...lphur is yellow, sometimes orange- logs are ...t ... Transparent to translu- wood till ... to 2-5. Specific gravity 2.07. without ...inguished by burning blue, and the... sulphur odour. The great reposi- ...s of sulphur are either beds of gypsum and ...associated rocks, or the regions of active or tinct volcanoes. In the valley of Noto and azzaro in Sicily, at Conil near Cadiz in Spain, ...x in Switzerland, and Cracow in Poland, it curs in the former situation. Sicily and the ighbouring volcanic islands, Vesuvius and the lfatara in its vicinity, Iceland, Teneriffe, Java, awaii, New Zealand, Deception Island, and ost active volcanic regions, afford more or less lphur. The native sulphur of commerce is ought mostly from Sicily, where it occurs in ds along the central part of the south coast and some distance inland. It is often associated th fine crystals of sulphate of strontian. It dergoes rough purification by fusion before portation, which separates the earth and clay with which it occurs. Sixteen or seventeen thousand tons are annually imported from Sicily into England alone. Sulphur is also exported from the crater of Vulcano, one of the Lipari Islands, and from the Solfatara near Naples. It is also found in the United States of America, on the Potomac, and in districts where sulphuretted hydrogen is evolved from mineral-springs. Sulphuric Acid is said to occur in the waters of the Rio Vinagro in South America, also in Java, and at Lake de Taal in Luzon in the Eastern Islands. —*Eng. Cyc.* Sulphuric acid has been detected in the fumes of volcanoes. Sulphur undergoes no alteration in the air at common temperatures. That of commerce, obtained from Pyrites, is often contaminated by metallic impurities, as Zinc Carbonate and Sulphate, Iron Oxide and Sulphuret, Arsenic, the Sulphuret, Silica, Magnesia, Alumina, and Carbonate of Lime. Flowers of Sulphur are sometimes contaminated by the presence of a minute quantity of Sulphurous (stated by some to be Sulphuric) Acid, formed by a portion of the Sulphur during sublimation uniting with the Oxygen in the apparatus. It should be freed from acidity by washing with hotwater, when it should not affect Litmus paper. —*Royle.*

(7963) *In Tenasserim, Sulphur* only exists in the ores that are found in the form of sulphurets, as the sulphuret of iron, the sulphuret of antimony, the sulphuret of lead, and the sulphuret of copper ; but native sulphur has not been found in the Provinces.—*Mason.* The *Sulphur* from Canara and Nellore is of fair quality, and in pure though small crystals. This substance is found in small quantities, in several districts of the Madras Presidency, as Salem, Masulipatam, Guntoor, Cuddapah and Trichinopoly ; it occurs along with Gypsum in marl and clay beds, and also very largely in the form of metallic sulphurets. The natives are acquainted with the modes of subliming sulphur, and they prepare it of indifferent quality for the manufacture of the gunpowder, which is used for Engineering purposes, &c. *M. E. J. R.*—This would appear to be a very rare production in India, we are told that about thirty miles north of Andipore in Upper Hindoostan, it is met with, but of a quality inferior to that brought from the Gulph of Cutch and Persia. Dr. Heyne tells us, in his Tracts Historical and Statistical of India (p. 186, 187), that he met with sulphur in small heaps and in tolerable abundance, at the Northern extremity of a lake which is near a small Village called Soorasany yanam, about 12 miles east from Aumlapore, and not far from Maddepolem. It was in a loose soft form, or in nodules of a greyish yellow color. The greater part of the Sulphur, which is exposed for sale in the Indian provinces, is brought from Muscat, from Sumatra, or from the Banda island called Gonangapi, where it is a volcanic production. In China, Dr

Abel, had some most beautiful and splendid native sulphur brought to him from the crater of Gunang Karang. We know that it is a product of the Philippine islands particularly in the island of Zeyti, whence the gunpowder works of Manilla are supplied: most of the sulphur brought to Hindoostan contains a considerable portion of orpiment, being much less pure than either that which is dug out of the solfaterra near Naples, or that imported from Sicily, which last, Dr. Thomson says, contains seldom more of impurity than about three per cent of a simple earth. A bright shining yellow sulphur is sold in the bazars of lower India under the name of Nellikoya gundagum (Tam.) By Dr. F. Hamilton's excellent account of Nepaul, p. 78, it appears that Sulphur is there numerous: this useful article is also found in Persia in mountains behind Takran and in mountains south of Kelat in the province of Mekran. It is met with in Cabul in the District of Balkh, it is also a product of Armenia, of Moultan, of China and Thibet; also, according to Morier, at Balianlia in Persia in the District of Kabul. With regard to the Indian Islands, Mr. Crawfurd in his history of the Indian Archipelago says (Vol. I. p. 201,202) that sulphur is found in all the pseudo volcanoes of these islands in great purity, but that the manufacture of gunpowder amongst the Malays is very imperfect. Sulphur would not appear to be found in great abundance in our Indian dominions: In the district of Oudipour in upper India, it is to be met with, but of a quality inferior to that which is brought from the gulphs of Cutch and Persia. In Travancore it has, I understand, says Ainslie, been discovered by the ingenious and indefatigable Captain Arthur, of the corps of Engineers, in combination with Iron, in the form of Pyrites, and also in combination with Alum. In Cotiole (in Canara) too, I am told, it may be procured. The greater part of the sulphur, however, exposed for sale in the Madras provinces, was in Ainslie's time brought from Muscat, from Sumatra, or from the Banda island Gonang-Api. Sonnerat tells us that it is common at Pegu, and we know it also to be a product of the Philippine islands.—*Ains. Mat. Med. p.* 45. Sulphur is in the Malay balirang, and in Javanese wálirang, essentially the same word. This name extends from Sumatra up to Celebes, where we find a new one for it, cholok. In one of the languages of the Philippines, the Tagala, strangely enough, the name is sanyaya, which is, no doubt, a corruption of the Malayan word sandawa, saltpetre. In the Bisaya, as well as in the Tagala, the name for gunpowder is maliling, doubtless a corruption of the Malay and Javanese name for sulphur. In the Madagascar, the name for it is sulifara, a corruption of the French soufre, from which it may be safely inferred that the article was unknown to the natives of this non-volcanic island until ...re le... to their knowledge by Europeans. I... cal... to say to what use the natives of the ...ealth. ...chipelago could have put sulphur, b... there is ...troduction of fire arms, unless to t... impure ...ture of fire-works, known by the nati... of the marchun and rabok. The Malay a... cur... lippine Archipelagos, the most extensive vo... canic region in the world, must necessarily contain a vast supply of sulphur, but hitherto it has been very little availed of for economic use. From the Philippines alone it is exported, the export being to China only, and at the price at Manilla usually of about a Spanish dollar of 4s. 2d. a cwt. Among these islands those which most abound in it are Luzon and Leyte, but particularly the last, where the article is of the best quality. A spanish writer asserts that the quantity is such at the volcana of Taal or Bombon, in the province of Botengas in Luzon, that many ships might be loaded with it. The difficulty, in all these cases, of obtaining a cheap supply, must arise from the absence of good roads, and the consequent costliness of transport.—*Crawfurd Dict. page* 412.

(7964) SULPHURIC ACID, Oil of Vitriol, Vitrolic acid, Spirits of Vitriol.

Rohazim Maulkibrit. Arab.	Gunduck-ka teil Guz

[illegible] powerfully corrosive. At first it feels [illegible] in destroying the cuticle, but soon acts [illegible] tic, charring both animal and vegetable [illegible] by combining with the water and [illegible] the carbon. It freezes at from— [illegible]°, according to its density, and boils [illegible]°. Its affinity for water is great, heat and condensation being produced on their union. It may be diluted with it to any extent. It unites with alkalis, earths, and metallic oxides, rapidly dissolving some metals, as iron and Zinc, when diluted with water. By the action of S. Acid on alcohol, Ether is produced.

Sulphuric acid used to be made in England by burning the imported Sulphur with a little Nitre. After the great increase which took place in the price of Sulphur, some manufacturers employed that obtained from Pyrites, which often contains Arsenic as an impurity. The proportion of Nitre was $\frac{1}{9}$ which was burnt with Sulphur either in the same chamber, lined with lead, and having its bottom covered with water, or in a furnace, from whence the vapours produced were conveyed into a similar chamber. The mode of making Sulphuric acid now varies from the above in many places, and has been described by Professor Graham. In this process Sulphurous Acid, from burning Sulphur, Nitric Acid vapour, and steam, are simultaneously admitted into oblong leaden chambers and, [illegible]honed that the vapours can for all frame [illegible]vly, and thus allow the whole bility. In [illegible]d Acid to be deposited.—*Royle.*

(7968) SUN-FLOWER, the English name of a genus of Plants called *Helianthus* from ἥλιος, the sun, and ἄνθος, a flower. Two reasons have been assigned for giving the plants of this genus this name: first, the resemblance of the large disc and ray of their flowers to the sun; and second, the tendency of these flowers, in a stronger degree than in other plants, to present their face to the sun. From this circumstance, the French Tournesol, Italian Girasole, an English Turnsol have been given. This is a gen consisting of very stately herbaceous plant and containing upwards of 40 species, all which are indigenous to America. It belongs the natural order *Compositæ*, and has the follo ing characters:—Head composed of ma flowers, the flowers of the ray being ligulate a neuter, the flowers of the disc tubular and herm phrodite; involucre irregularly imbricated, t outer scales foliaceous, the inner ones scal receptacle plane or convex, covered with oblo acute scales; tube of the corolla of disc flowers short, 5-toothed; style appendiculate Fruit an achenium compressed laterally; pa pus in the form of two lanceolate acute decid ous scales. The leaves are opposite, sometim superiorly alternate, and either entire or toothe The whole plant is scabrous or villous. T flowers are solitary, and of a yellow oran colour.

Helianthus annuus, Annual Sun-Flower, is herbaceous annual plant with thick rou stems from 6 to 20 feet in height; leav alternate, petiolate, nearly heart-shaped, cren lated or dentated, rough. The heads a large, from one to two feet in diamet and composed of a multitude of flowers of beautiful yellow colour, terminal, solitary, incl ed, the disc vertical and oftenest facing t south. This species is the largest of the gen It is indigenous in Mexico and Peru; it w early introduced into Europe after the discov of America, and has since been very genera cultivated in gardens, on account of its v large and handsome yellow flowers. The pl however in Europe never attains the height the flowers the size they do in their native and climate. The albumen of the seeds of t plant contains a large quantity of oil; and it been proposed to cultivate it for the sake of taining this oil, which is very palatable, might be used for the table. Cows and ox horses, sheep, pigs, rabbits, and poultry are fond of it. When torrified in the same man as the seeds of coffee they make an agreea drink, which may be used as a substitute that article. *H. multiflorus*, Many-Flowe sun-Flower, is not so high a plant as the l nor are its flowers so large. It has vivaci roots, which produce numerous herbaceous ste which are branched and rough; its leaves alternate, petiolate, dentated, the inferior o are heart shaped, the superior oval and acun ate; the heads of flowers are numerous and inclined. It is a native of Virginia.

Helianthus tuberosus, Tuberous Sun-Flowe Jerusalem Artichoke. This latter name is a l barous corruption of the Italian Girasole, this cies having been introduced into Europe at Farnese Garden at Rome, whence it was origin distributed. The roots are composed of a nun

of oblong tubercles, very large and fleshy, reddish outside and white within, resembling a potato; the stems are herbaceous and upright; the leaves are alternate and opposite, petiolate oval, rough; the heads of flowers are yellow, and small compared with the two preceding species. It is a native of Brazil. In France it is also known by the name of Topinambour and Porire de Terre. According to Braconnot and Payen, the tubers do not contain fecula, but a vegetable principle called Inulin, or Dahlin. These tubers, when cooked, form a good substitute for potatoes, and by some are even preferred.

Some of the species secrete a resinous juice, which is found to exude from the various organs of the plant. This is most observable in the *H. thurifer*, in which the resinous matter runs down the stem. This is sometimes observed to occur in the flowers of *H. annuus*. The *H. Indicus* of Linnæus and our gardens is probably only a variety of *H. annuus*, and is not a native of India, as its name would imply. This last species, according to Dr. Royle, is cultivated by the natives of India for the purpose of obtaining oil from its seeds.—*Eng. Cyc.*

(7969) SUN ROSE. HELIANTHEMUM.

(7970) SUNG-I-BUSRA is an officinal article at Lahore. It is a compound earthy mass of a greyish color, occasionally varying (from the different composition or manipulation) sometimes it is to be met with in small pieces, at other times in a tubular form, as thick as a finger. Whether its name, "basree" be from Bassora, or from vision, as formerly the lapis divinus was used is not known. It is certain that no Zinc is in it. But in Ainslie's Mat. Indica, *Vol.* 1, *p.* 573, Sung busrie is erroneously stated to be Zinc. According to the analysis made by the Professor of Chemistry, Dr. Joseph Redtenbacher, in the Chemical Laboratory at the Thersianum in Vienna, the constituent parts of this compound are: clay, magnesia, silica, and oxyde of iron. It is probably, prepared from Diorite, the analysis of which showed the same ingredients. Sung-e-Busree (1) proved an excellent remedy in the cholera epidemy at Lahore, in 1835.—*Thirty five years in the East, by Dr. Honig. p.* 351.

(7971) SUNG DIRAN. An impure and weak Nitro-muriatic acid, made by attars by mixing equal parts of alum, nitre and salt with a little water in an earthen pot (gurra,) and distilling; an acid fluid comes over that is applied to cure herpetic eruptions.—*Genl. Med. Top. p.* 152.

(7972) SUNG-I-MISRE. A red and white stone, imported via Pali, is used as an aphrodisiac: one tola for one anna.—*Genl. Med. Top. p.* 152.

(7973) SUNG SURMIYA. A concretion from the head of a fish comes from Delhi, used as an aphrodisiac. Sold at eight annas a tola.—*Genl. Med. Top. p.* 152.

Billo*irundo fuciphaga*. There is another Velv*fuciphaga*, the Linchi of the Javan- do[illegible] five inches long, nearly an inch than *H. esculenta*, which has a white odomen and longer wings in proportion its size. This species constructs its nest mosses and lichen connected by the me glutinous substance which composes the ible nest of *H. esculenta*. Dr. Horsfield, who ates this in his 'Systematic Arrangement and escription of Birds from the Island of Java' Linn. Trans., vol., xiii.), there remarks that e specimens of *H. esculenta* examined by him Java and those which he brought home differ om Latham's description in being uniformly of blackish-colour without a white extremity to e rectrices. Bontius, who gives a rude cut the nests adhering to the rock, with the birds tting and approaching, describes his birds, in ...e chapter 'De nidis hirundinum edulibus,' above referred to, as 'Aviculæ parvæ discolores, hirundinum specie.' Specimens of *H. esculenta* and *H. fuciphaga* are preserved in the Museum of the East India Company.

(7982) *Macropteryx*.—Tarsus remarkably sho[illegible]nterior toes long; the outer wheels and [illegible]han the middle; the inner short- for all fra[illegible]very short. Tail long, forked. It bility. I[illegible]ndia. (Swainson).

arch of 2[illegible] *longipennis*.—Above obscure signed a[illegible]throat, breast, and lower part of is chiefl[illegible]t-gray; belly, spot on the scapu- side of [illegible] over the eye, white; ears rufous; inches [illegible] incumbent crest. Mr. Swainson Sati[illegible]*acropteryx* intermediate between the beauti[illegible]ts and the Swallows. To the first, seen spec[illegible]s allied by its strong scansorial logs are not [illegible] by the length and fixed posi- wood till sa[illegible], and the depression of the without [illegible]. The Wood-Swallows of Australia and India there[illegible]though closely related to, the *Hirundi-* [illegible], but differ in the structure of their bills and feet. Mr. G. R. Gray arranges them under his sub-family *Dicrurinæ* amongst the *Ampelidæ*. They belong to the genus *Artamus*, which is often placed in the *Laniadæ*, and is thus defined: —Bill gradually arched from the base, where it is very broad. Culmen thick and convex without any ridge; the base dividing the frontal feathers, and somewhat dilated. Rictus bristled. Nostrils wide apart, naked, small without a membrane, and pierced in the bill. Feet short, strong. Wings very long and pointed; the first quill longest. Tail short. (Swainson.)

(7983) *Artamus leucorhynchos* is the *Lanius leucorhynchos* of Gmelin, Pigreische Dominiquaine de Philippines of Sonnerat, and White-Bellied Shrike of Latham. Size rather larger than a sparrow, and in shape much more elongated. Head, neck, breast, back, wings, and tail black. Belly and upper part of the rump white. Under part of the wings (which are very long, and reach at least an inch beyond the tail) gray. Bill grayish, conical, and very strong, slightly curved at its extremity, and its base surrounded with stiff bristles directed forwards. Legs black. Sonnerat states that this bird flies with rapidity, poising itself in the air like the swallows. It is, he adds, an enemy to the crow; and although much smaller, the wood-swallow not only dares to oppose but to provoke him. The combat is long and stubborn, sometimes continuing for half and hour, and concludes with the retreat of the crow. Perhaps, says Sonnerat, the crow despises this too feeble enemy, which only harasses him, and avoids his strokes by his activity, darting away, returning as he sees his opportunity.—*Eng. Cyc.*

(7984) SWEET BRIAR. Rosa rubiginosa.

(7985) SWEET FLAG, ANDROPOGON CALAMUS AROMATICUS. Sweet Calamus.

Kist-ul-durrera, Wuj, ARAB.	Calamo aramatico, IT.
Shwet Buch, BENG.	Kawa-sob, JAP.
Bagy, CAN.	Calamus aromaticus, LAT.
Tachxudogbo, COCH CHIN.	Vudge, PERS.

Kussub-bewa, Godavuz, Venkund, Wuj Igir, GUZ. HIND.	Vudza, TEL.

Sweet Calamus, the aromatic, which was c equal celebrity with Spikenard, mentioned b the same authors, and procured from th same country, is described by Dioscorides un der the name of Κάλαμος ἀρωματικος. It is sup posed by Sprengel and some authors that th *Acorus Calamus* of botanists is intended, whic is possessed of slight aromatic properties, is con mon in European ditches, and is likewise four in India in mountainous situations. This known to the Arabs by the name Wuj, which a pears to be a corruption of the Hindoo Buc Sanscrit Vacha, and has in the Arabian worl the name Akoron assigned as its Greek sync nyme, no doubt intended for the Ακορον of Dio corides. Therefore there is no foundation for th opinion of Sprengel that this Acoron is the *Ir pseudacorus* of botanists.

Calamus aromaticus is described by Dioscorid immediately after Σχοῖνος, or Σχῖνος, which usually translated *Juncus odoratus*, and is a knowledged to be the *Andropogon Schœnanth* of botanists, commonly known by the name Lemon-Grass. This has also had the names Camel's Hay, Palea de Mecha, &c., applied to i *Schœnanthus* is evidently compounded of 'scho nus' and 'anthos' (ἄνθος, 'a flower,'). Theophrast treats of Calamos and Schœnos together, a states that they were found among the mountains Libanus, on the shores of an extensive lake; b

Burckhard in such situations could only find rushes and reeds. It is possible therefore that a Syrian locality may have been assigned to drugs obtained from more distant countries by the route of the Euphrates, for Dioscorides says they are produced in India. By Hippocrates they are called Κάλαμος εὐώδης and Σχοῖνος εὔοσμος, also Κάλαμος σχοῖνος (Hipp., f. 5 p. 138, l. 17), evidently showing that if they agreed in properties, they had also some resemblance in nature. If we desire to find something similar to *Schœnanthus*, and possessed of still more aromatic properties, we have only to search in the genus to which this belongs, and we shall find several plants famous for their agreeable odour. The roots of *Andropogon muricatum*, commonly known in the shops of Britain by the Tamul name Vitivayr and made into small bundles for brushing velvet, are remarkable for their fragrance: hence several essences are now prepared from them in Paris. The roots are also well known in India by the name of Khuskhus, being used throughout the several Presidencies for making tattees; these thatched screens being fitted to doors and windows, have water constantly sprinkled over them; the hot air in passing through becomes much cooled by the great evaporation, and enters the room both cool and refreshing, diffusing a delightful fragrance. The aroma here depends on the presence of a principle analogous to myrrh. But other species are still more fragrant, and secrete odorous volatile oil in sufficiently large quantities to be profitably distilled. Of these, Lemon-Grass, or *Andropogon Schœnanthus*, is the best known. The infusion of its leaves is often employed in India as a pleasant stomachic, and Lemon-Grass Oil is probably distilled from them. *A. Nardus* (?) is another species, called Ginger or Spice-Grass, by Ainslie, which is said by him to be common in the Courtallum Hills and the Indian Peninsula, where the natives occasionally prepare with it an essential oil useful in rheumatism, and use the infusion of its leaves as a stomachic. *A. Iwarancusha* is a species which comes near *A. Schœnanthus* in habit and taste. It skirts the bases of the mountains of north-west India, and was found by Dr. Blane and by Dr. Boyd about Hurdwar: it was considered by the former to be the Spikenard of the ancients. Dr. Royle also found it near Hurdwar, and in the upper parts of the Doab of the Ganges and Jumna rivers, and he states ('Illustra. Himal. Bot.' p. 425) that it is there called Mirchiagund, with Izkhir given as its Arabic, and Iskhinos as its Greek synonym; and infers that it may have been the Σχινος of the Greeks as well as *A. Schœnanthus*. But another species is still more extensively diffused, and still more remarkable for its very powerful and delightful fragrance. This is the species which yields the Grass-Oil of central India, commonly called Oil of Spikenard. It extends southward to between the Godavery and Nagpore, and northward to the Delhi territories, but probably still farther north, as it is cultivated in a dry and barren soil. In central India generally at Namur, Ellichpore, &c., a very fragrant oil is distilled from this plant. There is impure is highly valued in the East as a substitute of the added to the finer expressed oils employed for anointing the hair or the bodies of the natives. It is also much esteemed as an external application in rheumatism, and has been introduced into practice in England, and is highly valued by some, though unknown to the generality of practitioners. It has the advantage of diffusing an agreeable odour at the same time that it is efficacious as a stimulant remedy. This or the preceding species extends into Afghanistan. Sweet Cane, or Calamus, being described by Dioscoride immediately after Σχινος, which is generally acknowledged to be *A. Schœnanthus*, appears to Dr. Royle to belong to the same genus, and indeed to be the above far-famed species, as *Calamus aromaticus* is thought also to be the Sweet-Cane and the rich aromatic reed from 'a far country' of Scripture. He states that there is no plant which more closely coincides in description with everything that is required than the tall grass which yields the fragrant Grass-Oil of central India, and which he has named *Andropogon Calamus-aromaticus*. (7989) SWIETENIA, a small [illegible]arges and be- of the natural family *Cedrilaceæ* [illegible]til it is about quin in honour of G. van Swieten[illegible]ne, from the *Swietenia* is characterised by ha[illegible]um, the legs 4-5-cleft calyx; petals 4 to 5, de[illegible] acarus thus mens 8 to 10, the filaments united [illegible]size until it a toothed tube, bearing the anther[illegible]isible to the side: stigma peltate; ovary 5-[illegible]r. Hassal gave a stipes; seeds winged. Th[illegible] of his Microsco- few in number are found in t[illegible] of Brown world, form large trees, and [illegible] the True Hogs. timber.—*Eng. Cyc.*

(7990) SWIETENIA CHICKRASSA. Chittagong Wood.

Nga-bagi, Burm. | Chickrassa, Hind.

S. Chickrassa, is now formed into a new genus, Chickrassia tabularis. This Indian tree is greatly admired for its beauty. The wood is very light coloured, close grained and most elegantly veined and much employed for furniture, and cabinet work.—*Eng. Cyc.* It grows in abundance in the Chittagong woods, and is much esteemed by the Cabinet makers as being little inferior to its congener the Swietenia Mahogani (Willd.).—*Ains. Mat. Med. p.* 210. It is found along with Teak in the Pegu districts, but it is not very plentiful: wood, red; equivalent to mahogany.—*McClelland.*

(7991) SWIETENIA CHLOROXYLON. *Syn.* CHLOROXYLON SWIETENIA. *Cedrelaceæ*, Ill. 56 bis. Satin wood tree.

Billoo Kara, TEL.	Kodawah porsh, TAM.
Velva Maram also Moodoodi, TAM.	Boorooch gaka, CYNG.
	Dhoura, HIND.

S. chloroxylon is another species, which has been formed into a new genus, and is now *Chloroxylon Swietenia.*

It is the tree yielding the beautiful East Indian satin wood, which is of a deep yellow colour close grained, heavy and durable.—*Eng. Cyc.* This chiefly Ceylon tree grows abundantly in the mountainous districts of the Madras Presidency, in the Jungles of Goozerat and the Deccan, but seldom attains a large size. Occasionally planks of 10 to 15 inches in breadth may be procured. The wood is very close grained, hard and durable, of a light orange colour, takes a fine polish, and is suited for all kinds of ornamental work, but is somewhat apt to split. For picture frames, it is nearly equal to American maple. The timber bears submersion well. In some instances it is beautifully feathered but it has the peculiarity of losing its beauty by age, unless protected by a coat of fine varnish.—*M. E. J. R.* The Billu Kara of the Circars, says M. Rohdes, is a most serviceable hard wood, well suited for naves of wheels and, were it procurable in any quantity, for all frame work requiring strength and durability. In Ceylon, the Peradenia bridge, a single arch of 205 feet on the road to Kandy, was designed and principally executed in this wood : it is chiefly procured in the jungles on the Eastern side of Ceylon where it attains a diameter of 18 inches of sound wood. The flowered or feathered Satin wood when first polished is one of the most beautiful woods in the world. Mr. Rohde has seen specimens surpassingly beautiful, these logs are not distinguishable from ordinary satin wood till sawn, and twenty or forty may be cut without one of any beauty being found. The feathered satin wood seems very liable to sever when dry and old ; articles of satin wood get darker and lose much of their beauty by age, unless protracted by a coat of fine varnish.—*Rohdes.* Though satin wood is highly esteemed in Ceylon, where it attains a large size, until very lately Dr. Wight had never seen it exceed a good sized shrub in India. Planks have since been obtained 15 inches broad from the Animullay Forests. In Ceylon where it is abundant and well known, it is very highly esteemed, and their shell boxes are made of it.—*Wight.* An essential oil is found in *Chloroxylon Swietenia.*

(7992) SWIETENIA FEBRIFUGA of Roxburgh has been formed into a new genus, *Soymida.* [SOYMIDA.]—*Eng Cyc.*

(7993) SWIETENIA MAHOGANI. MAHOGANY TREE. Indigenous in South America, and naturalized in some parts of India. The bark is used in the West Indies as a substitute for c chona. It is very astringent, but contains alkaline principle, and is not used by Europe practitioners.—*O' Shaughnessy, page* 248. T is the most important species, and, from the moval of the others to separate genera, n nearly alone constitutes the genus : is a nat of Compeachy and of the West Indies. It i lofty branching tree with a large spreading he and pinnate shining leaves. The timber wh is so well known from its extensive employm for furniture and cabinet making is of a redd or yellowish brown colour, of different degrees brightness, much mottled and streaked, ve little liable to shrink or warp, free from taste smell, except when kept for some time, when acquires an agreeable odour from the exudati of a semi-resinous juice which serves to prese the wood from the attacks of insects. It d not appear to have been imported into gr Britain before 1724. The quality of the wo varies much according to the situations in wh it grows, that which is produced on rocky s and exposed situations is the best. Spanish mal gany is imported into England, in logs of about feet long and from 20 to 26 inches square. Fr the elevated parts of the West Indies and fr the Spanish Main the wood is close-grained a of a darker colour than the Honduras Mahoga This is imported in logs of from 2 to 4 f square though both kinds are no doubt produ by the same tree. Some years ago the Mess Broadwood gave the large sum of £ 3000 for th logs of Mahogany, which were each about 15 f long and 38 inches square. The wood v extremely beautiful and capable of taking t highest polish.—*Eng. Cyc.* See MAHOGAN

(7994) SYLHET, possesses a few manuf tures. The Natives there excel in some kin ivory work. They manufacture a variety of ar cles, including Ladies' Bonnets. They also ma shields of Buffalo and Rhinoceros' hides, wh are celebrated throughout India for their du bility and polish. The varnish is made of t juice of the Semecarpus anacardium (or Indi marking nut,) which has already attracted a tention. One description of target call *afla-o-i*, which is made here, is not varnis ed but is rendered by some peculiar pr cess of preparing the leather, semi-transparen The otter skins of the District are an article traffic, and would bear a comparison with simil furs in Europe. Considerable quantities of the are prepared annually both here and in Myme sing. They were formerly sent to Thibet, b they are now chiefly exported to China. T other manufactures for which Sylhet is fame are sword handles, morahs, articles of brass wo (made at Toroff,) and fine " sectalpatee" ma such as are commonly used in Bengal, for cov ing the seats of chairs, beds, and couches. Th place has also long been celebrated for the m

paration of certain perfumes, as the attars of *uggur* or lign aloe, and *naugissore* (Mesua ferrea); also several compounds of essential oils, of which that of Cassia is one of the principal ingredients, the tree (Aquilaria agallocha. Roxb.), which yields the lign aloe, grows in the Naga country between Sylhet and Assam, also in Cochin China and Siam. Both the wood and the essence extracted from it at Sylhet, are purchased by Mogul merchants for exportation to Bassora, and other Mahomedan countries, where they are held in high estimation and much used, the attar, as a perfume, and the wood, for fumigating apartments and cloths. Lign aloe is interesting from its antiquity as an export from India, being an article that was formerly much used as incense in Western Asia. It is mentioned under the name of *agallochum* in Scripture.—*Dr. Taylor.* Amongst the articles of export, are a variety of parti-coloured cloths, generally known by the name of Sylhet cloths. Some of them are dyed of rich colours, and being of a strong durable texture, are well adapted for table covers, to which purpose they are usually applied in the Eastern part of Bengal.

(7995) SYMPHOREMA. Of this genus, Wight in Icones, gives involucratum, 362; polyandrum, 363; and *polyandrum*, 1474.

(7996) SYMPHOREMA INVOLUCRATA. VERBENACEÆ, A species of St. Peter's Wort, cultivated by seed or cuttings.—*Riddell.*

(7997) SYMPHYTUM OFFICINALE. Συμφυτον, Diosc. iv. p. 9.

Sunkootun, HIND

Roots large, externally black, and branching, about a foot long, the thickness of the finger, fleshy, brittle, succulent, and pulpy. Inodorous, taste, sweetish and mucilaginous. The plant is highly mucilaginous, and rather astringent, it also contains sugar and albumen. The recent root is in popular use in France in cases of rupture and bruises. Indeed the plant derives its name from its supposed virtue in consolidating wounds.—*O'Shaughnessy, page* 496.

(7998) SYMPLOCOS (from συμπλοκή a knitting together), a genus of Plants belonging to the natural order *Styraceæ*. This genus was made the type of a natural order, *Symplocineæ*, by D. Don, which contained only this example. It has a 3-parted half-inferior calyx; rotate monopetalous 3-10-parted corolla, imbricate in æstivation; indefinite stamens inserted in the lobe of the corolla, with the filaments cuspidate at the apex, and polyadelphous at the base; erect anthers bursting longitudinally; 3-5-celled ovary with 4 ovules in each cell. The fruit is a fleshy drupe, containing a 3-5-celled nut; the cells containing but one seed, which has an inverted embryo lying in albumen, and a superior radicle. The species are trees, having alternate either entire or serrated leaves without stipules, and turning yellow in drying. The flowers are axillary, sessile, or pedunculate, few, of a white or scarlet colour, and supplied with bracteas at their base. Upwards of 30 species have been described. They all possess an astringent principle in their leaves, and some are used in dyeing.—*Eng. Cyc.* Wight, in Icones, gives Symplocos foliosa, 1234; Gardneriana, 1231; microphylla, 1232; monantha, 1236; nervosa, 1235; obtusa, 1233; pendula, 1237; pulchra, 1230; *racemosa*, 1235.

(7999) SYMPLOCOS RACEMOSA, RACEMED SYMPLOCOS.

Lodh. HIND.

Racemose-Flowered Symplocos. Leaves oblong glabrous, serrated; flowers arranged in racemes, mostly axillary; nut of fruit 3-celled. This plant is a native of Burdwar and Midnapore, in Bengal. It is used extensively by the natives as a red dye.—*Eng. Cyc.* Grows in the Kotah jungles; the bark, used to dye red with, is exported.—*Genl. Med. Top. page* 197. The bark of the root is used, and the tree is found in Rajpootanah, but the root is imported into Ajmere from Delhie, and used in dyeing red; also in medicine, being considered heating, and promotive of the secretions; used in mesalihs of animals: four seers are sold for one rupee.—*Genl. Med. Top. p.* 144.

(8000) SYMPLOCOS. *Species.* A few of the people of Lampteng in Sikkim find employment in drying the leaves of a shrub, one of the genus Symplocos, for the Tibet market, which are used as a yellow dye.—*Hooker, Him. Jour. Vol.* II. *p.* 41.

(8001) SYMPLOCOS SPICATA. The nuts of *S. spicata* are very hard and resemble a little fluted pitcher. This plant is a native of Silhet. —*Eng. Cyc.*

(8002) SYNANTHEREA. A great and very natural order, usually termed *Compositæ*, and named as above from their anthers being collected into one adherent mass. They have been also named *Syngeneseæ* from the same cause. It is composed of herbaceous, rarely woody plants, with compound flowers, that is, bearing a variable number of flowers, sometimes uni-sexual, and sometimes hermaphrodite, united together on a common receptacle. They occur in all parts of the globe; in France they constitute as much as one-seventh of all the phanerogamic division; at the Cape one-sixth; in Germany one-eighth; in America one-sixth. Dr. Wallich enumerates 426 India species from the plains and mountains of India. A bitter principle abounds in several of this order, for example in the Absinthiums or wormwood; essential oil exists plentifully in the camomiles and pellitory, and these species are at the same time exceedingly bitter; the seeds of many possess a fixed oil in such quantities as to render its manufacture economical; for instance, the

seeds of the sunflower, and ramtill. The essential oil resides in the periaperm, the fixed oil in the almond.

The proper juice of some Synantherеæ is milky and rather narcotic, still but few are justly suspected of dangerous properties. Starch is but in very small proportion in any of the species, hence few can be deemed alimentary, though from the presence of mucilage, saccharine matters, and extractive or modified bitter principles, some are used as table vegetables, such as the artichoke, lettuce, and endive ; no peculiar principle of much importance has been detected in the plants of this order.

In their medical uses these plants are tonic, febrifuge, vermifuge, or emollient. The properties of one species generally co-exist in all the congenerous individuals, and thus the research for substitutes is much facilitated.—*O'Shaughnessy, page* 405.

(8003) SYNDESMIS TAVOYANA. MERGUI RED-WOOD.? Mergui red-wood is a valuable dye wood for both black and red, but more especially for orange. From an article in the Journal of the Asiatic Society, it appears that " a number of experiments, made at the request of Mr. G. Swinton, by Mr. Thomas Speir, upon the Mergui dye wood, prove that it affords, with the mordants commonly used by dyers, colours equally bright, and of a more permanent nature than those of most other dye woods. The colours imparted to silk with different mordants were as follows :—

1.—*Muriate of tin.* Three shades of orange, varying with the temperature of the bath, and the time of immersion.

2.—*Acetate of alumin.* Two shades of flame colour.

3.—*Acetate of iron.* Two shades of drab.

4.—*Ditto, with a weak decoction of galls.* A fine black, two shades.

5.—Mixed with *manjit*, a variety of red and pinks are obtained, but not perhaps equal in intensity to those of the *manjit* alone. The chief attraction of this wood as a dye, is the orange colour which it yields with the aid of muriate of tin and acetate of alumina, of a great variety of shade.—*Mason.*

These results shew that the Mergui wood is deserving of further attention, and that it may become eventually an important article of commerce with our possessions on the Tenasserim Coast." It is not quite certain, however what tree produces, the Mergui red-wood. The flowers which accompanied the specimens of the wood sent to Calcutta, belonged to the Burman black varnish tree, yet Mr. Maingay who sent them, thought it a different tree. Mr Mason imagines there was some mistake, and that the Mergui red-wood is identical with the Tavoy red-wood, viz. *Syndesmis Tavoyana.—Mason.*

Tavoy red-wood makes handsome furnit and is used in Tavoy for the same purp to which gum kino wood is applied at M main. When the wood is steeped in fe ginous mud, it turns jet black, and looks ebony. The large cylinder knobs, one or inches in diameter, so often noticed in the of Karen women at Tavoy, are made of wood after the colour has been changed.—*son.*

(8004) SYNGNATHIDÆ, a family of Fis embracing, according to some authors, the P Fishes, the Sea-Horses, and the Winged S Horses. These forms are sometimes assig to distinct families, as in the following defi tions :—

(8005) *Syngnathidæ*, Pipe-Fishes.—Body p longed, slender, linear, or angulated ; sn greatly prolonged, cylindrical ; mouth termi vertical. Ventral fins absent ; caudal fin wa ing in some.

(8006) *Hippocampidæ*, Sea-Horses.—H and body compressed ; snout narrow, tubul mouth terminal. Pectorals small ; dorsal sing caudal fin wanting.

(8007) *Pegasidæ*, Winged Sea-Horses.—B broad, depressed ; snout suddenly contract narrow, somewhat protractile ; mouth termi beneath. Pectorals generally large ; caudal small. They all agree in having the endo-s leton partially ossified ; exo-skeleton gano gills tufted (hence the group is named *Lop branchia*), in the opercular aperture being sm and the swimming-bladder without an air-du We shall illustrate this family by a short descr tion of the British species :—

(8008) *Syngnathus* has the body elongat slender covered with a series of indurated pla arranged in parallel lines. Head long ; b jaws produced, united, tubular. No ventral fi In certain of the species the males are furnis with an elongated pouch under the tail ; th are called marsupial, and include the Brit species *S. Acus* and *S. Typhle.*

(8009) *Syngnathus Acus*, the Great Pipe-Fi is one of the most common forms of the genus. is found on many parts of the British coast, so times at low-water amongst sea-weeds, at ot times in deep water. The most curious feat in the economy of this fish is the fact that roe is transferred from the belly of the female the pouch of the male.

(8010) *Syngnathus Typhle* (Linnæus), Deep-Nosed Pipe-Fish, Lesser Pipe-Fish, Shorter Pipe-Fish ; *Acus Aristotelis* and *Typ antiquorum* of Willughby. This fish is distingui ed from the last by the more compressed form the jaws. From the British species it is dist guished by the possession on the part of male of a pouch for the reception of the o The habits of this fish resemble those of the la

(8011) *Syngnathus æquoreus*, the Æquor

Pipe-Fish. This fish has no subcaudal pouch. It is comparatively rare on the British coast.

(8012) *Syngnathus anguineus*, the Snake Pipe-Fish. Although this and the preceding species possess no subcaudal pouch, the ova after exclusion from the female are carried by the male in separate hemispheric depressions on the external surface of the abdomen.

(8013) *Syngnathus ophidion*, the Straight-Nosed Pipe-Fish, is known by its stright nose. It is about nine inches in length.

(8014) *Syngnathus lumbriciformis*, the Worm Pipe-Fish, is the smallest of the British species. It has been taken on various parts of the coast. It does not exceed five inches in length. The young of this species have been observed to undergo a curious metamorphosis. On their escape from the egg the tail is covered with a fin-like membrane, and it also possesses pectoral fins. During their growth the caudal membrane and pectoral fins are absorbed.

(8015) *Hippocampus*.—The Jaws are united and tubular, the mouth placed at the end. The body compressed, short, and deep. The whole length of the body and tail divided by longitudinal and transverse ridges, with tubercular points at the angles of intersection; both sexes have pectoral and dorsal fins; the females only have an anal fin; neither has ventral or caudal fins.

(8016) *Hippocampus brevirostris*, the Sea-Horse, or Short-Nosed Hippocampus, is occasionally met on the British coasts. The habits of these creatures are very singular. When swimming about they maintain a vertical position, but the tail is ready to grasp whatever meets it in the water. It quickly entwines in any direction round weeds or other objects, and when fixed the animal intently watches surrounding objects and darts at its prey with great dexterity. When two are together they often twist their tails together. Their eyes move independently of each other, as in the chameleon.

(8017) *Pegasus* has a snout as in the previous genera, but the mouth is under it, and moveable. Two distinct ventral fins behind the pectoral, which are often large, hence the name of *Pegasus* or Flying Horse. The species are found in Indian Seas (Yarrell, *History of British Fishes*; Adams, *Manual of Natural History*.)—*Eng. Cyc.*

(8018) SYRINGA (from σῦριγξ, a pipe), the name of a genus of Plants belonging to the natural order *Oleaceæ*. The English name of this genus, Lilac, is said to be derived from 'lilag,' the Persian for a flower. It is known by a small 4-toothed calyx; funnel-shaped corolla, with a 4-parted limb; 2 stamens; a trifid stigma; a 2-celled, 2-valved, 2-seeded capsule; the valves boat-shaped, with a dissepiment in the middle. The species are natives of Europe and the colder parts of Asia. They are deciduous shrubs, with simple leaves, having purple or white flowers, which are arranged in beautiful thyrsoid terminal panicles, and are very fragrant.—*Eng. Cyc.*

(8019) SYRINGA is also the name that is commonly but improperly given to the species of *Philadelphus*, or Mock-Orange. The name *Syringa* was given to the Lilac on account of its stems being used for the manufacture of Turkish pipes. The stems of the *P. coronarius* are also used for the same purpose, and equally with the Lilac it had the name of Pipe-Privet, or Pipe Tree, given it when first introduced into great Britain and afterwards the name *Syringa*.—*Eng Cyc.*

(8020) SYRINGA CHINENSIS, Chinese Lilac. Leaves ovate-lanceolate. Flowers purple. It is a native of China. In character it is intermediate between *S. vulgaris* and *S. Persica*, and agrees with a hybrid plant produced at Rouen by M. Vain, and called *S. Rotomagensis*, the Rouen Lilac. It is a plant that grows vigorously, and attains a height of ten or twelve feet. The sorts known in nurseries as the Belgic Lilas de Marly and the Lilas Saugé, are varieties of this species.—*Eng. Cyc.*

(8021) SYRINGA EMODI has elliptical-oblong leaves, glaucous beneath, attenuated at the base, and acuminated at the apex, with purple flowers. It is a native of Kumaon near the Himalayas.—*Eng. Cyc.*

(8022) SYRINGA PERSICA, the Persian Lilac. Leaves small, lanceolate. Flowers purple. It is a native of Persia, and is a small shrub, from four to six feet high. It is one of the most ornamental of low deciduous shrubs, and on that account is very commonly cultivated. When planted in pots and forced, it may be made to flower at Christmas; but by this process the fragrance of the flowers is lost. Of this species also three varieties are found in English nurseries, the White, the Cut-Leaved, and the Sage-Leaved Persian Lilacs.—*Eng. Cyc.*

(8023) SYRINGA VILLOSA has villous leaves, and is found in China on mountains about Pekin, but neither of these species is cultivated in England although both would probably bear the climate.—*Eng. Cyc.*

(8024) SYRINGA VULGARIS, the Common Lilac, known by its ovate heart-shaped pointed leaves. It is a native of Persia, Hungary, and the borders of the Danube. Dr. Sibthorp found it wild on Mount Hæmus, but not in Greece. This shrub has been long cultivated by the Turks, and was brought from Constantinople to Vienna by the ambassador Busbequius, in the middle of the 16th century, from whence it spread over the rest of Europe. It is now one of the commonest ornaments of our shrubberies blossoming, together with the laburnum, in May. It is one of the few shrubs that resists the injurious influence of the smoke of cities, and flourishes in great perfection in most of the squares of London. It grows to the

height of 20 feet and upwards, and sends up from the parent stem an abundance of suckers, which, if allowed to grow, form a dense mass of stems: these are commonly left, but if cut down as they are produced, the parent stem may be trained so as to grow as a small tree. It grows very fast, as much as from eighteen inches to three feet in the year, and endures, according to the soil, for twenty to fifty years. Several varieties are well known.—*Eng. Cyc.*

(8025) SYZYGIUM, a large tropical genus of Plants belonging to the natural order *Myrtaceæ*, so named from συζυγος, coupled, in consequence of the manner in which the branches and leaves are united together in pairs. The calyx-tube is obovate, with the limb nearly entire. Petals 4-5, forming a calyptra; stamens numerous, free; style single; stigma simple; ovary 2-celled, ovules several in each cell. Berry 1-celled, 1- or few-seeded. Trees, or shrubs, of a highly ornamental appearance from their smooth shining leaves, which are opposite and entire.

Of the species, *S. Guineense*, a native of the coast of Guinea and Senegal, has been employed as a remedy in rheumatism. *S. paniculatum*, a native of the Isle of Bourbon, is there called Bois a Ecorce Blanche. *S. Jambolanum* is a native of the East Indies, and there most extensively diffused, being planted near villages in clumps of trees, chiefly on account of its fruit, which is sometimes called Java Plum by Europeans, but Jamoon by the natives. It is a rich purplish colour, but of a subastring sweetish taste, which is more agreeable to native than to the European palate. The f is sometimes soaked for an hour in salt water, when it makes an approach to the flav of olives. The bark is astringent, and dyes brown colour; the wood is hard, close-grai and durable, and therefore much employe *Eng. Cyc.* Dr. Wight, in Icones, gives Syzyg *carophyllaceum*, 540; densiflorum, 999; J bolanum, 535-553; lanceolatum, 530; n osum, 552; oblatum, 622; rubicundum, 5 rugosum, 339; salicifolium, 539; and Ze nicum, 73.

(8026) SYZYGIUM JAMBOLANUM.

Jamoon, Hind.	Nœrala Mara, Can.
Nawel Marum, Tam.	Neradi, Tel.

A fine large tree of common occurrence, s ed for avenues; the fruit small, and somew astringent, sold in the bazars. The woo much used for ordinary purposes, but is of li value. Travancore 361, Mysore 21,22,37, sulipatam, Palamcottah 247, Bangalore 3 Hort. garden 45. The bark," Neradi Ba has been classed as a tanning substance Buchanan, in his journey to Mysore, and in Jury Reports of the Great Exhibition, bu proved a failure even with the careful mana ment of Mr. Bowden.—*M. E. J. R.*

T.

(8027) TABASHEER, Banslochun, Sugar of Bamboo,

Tabasheer, Arab.	Vanslochun, Guz.
Bansk, Beng.	Tabasheer, Hind.
Chuh-hwang, Chin.	Tabashir, Lat.
Oonamakoo, Unalie, Cyng.	Tabashir, Turk.
Banslochun, Cash.	Moongil ooppoo, Tam.
Tabachir, Fr.	Veduroo-ooppoo. Tel.
Tabaschir, Ger.	Banslochun. Beng.
	Tivakshera. Sans.

A siliceous concretion found in joints of the female bamboo. It is bluish white, concrete, adhesive to the tongue, at a red heat fuses into a transparent glass. It is composed of silica 70, potash 30, per 100. The Persians deem it tonic and aphrodisiac. The Arabs suppose it to be astringent. From its composition we are warranted in supposing it to be entirely inert.—*Faulkner. O'Shaughnessy, page* 694.

Some Tenasserim bamboos secrete tabasheer, which has a place among native medicinal substances.—*Mason.* It resists acid, is indestructible by fire; and forms, on being fused with alkalies, a sort of glass. It is much esteemed by the Hindoos, Persians, and Arabs as a powerful tonic, and is said by them to have great efficac internal bruises. It is imported into Bom chiefly from Singapore: small quantites are so brought from the Malabar Coast.—*Fa ner.* Dr. Irvine has often removed it f old bamboos at Hoshungabad. It is brou to Ajmeer from Hurdwar, and is used as aphrodisiac and in general debility. One ma is the dose, and it is sold at two tolahs for rupee.—*Gen. Med Top. p.* 128.

(8028) TABERNÆMONTANA, a genus Plants belonging to the natural order *Apo naceæ*, found in the West Indies and So America, also in Australia, India, and ot tropical parts of Asia. The genus is charac ised by having monopetalous inferior flowe corolla salver-shaped; stamens 5, include anthers sagittate: ovaries 2; style filifor stigma dilated at base, trifid. Seeds in a f cle, immersed in pulp. The flowers of m species are very sweet scented, and the dou flowered variety of *T. coronaria* is a very o mental shrub, and one of the most commo Indian gardens. The deep red pulp surroun

the seeds of this species appears capable of yielding a beautiful colour. The cream-like sap of *T. utilis*, the Milk-Tree, or Hya of Demerara, is not only of an innoxious character, but said to be very nourishing. It affords a remarkable example of a tree of this suspected family yielding an article of food. Some of the other species are employed as medicines in the countries where they are indigenous. The sap of *T. persicariæfolia* is considered a poison in Mauritius. The wood is employed in turnery. Dr. Wight in Icones, gives Tabernaemontana coronaria, 477; crispa, 470; dichotoma, 433; parviflora, 393; and recurva, 476.

(8029) TABERNÆMONTANA CORONARIA. GARLAND. TABERNÆMONTA.

Firki Tugar, HIND.,

Is the name of the single flowered Tabernæmontana, and Bura-Tugur that of the double flowered. Common in gardens at Kotah and elsewhere. This shrub is very ornamental and the flowers are fragrant during the night.—*Genl. Med. Top. p.* 186. In the Dekhan Tabernæmontana Coronaria, is a common shrub in gardens with dark shining leaves, flowers generally double, colour pure white, resembling wax, having a faint pleasant smell; propagated readily by cuttings.—*Riddell.*

(8030) TEBERNÆMONTANA CORONARIA, VAR: FLORA PLENA.

The foliage of the double flowered Garland Tabernæmontana tree very beautifully contrasts with its large blue white double flowers; which are often improperly called on the Tenasserim Coast, "wax flowers" The wax flower of Bengal is a trailing creeper, *Hoya carnosa*, which has been recently introduced into European gardens. The single flowered variety is seen occasionally but not often.—*Mason.*

(8031) TABERNÆMONTANA PERSICARIÆFOLIA, POLYGONUM LEAVED TABERNÆMONTANA.

Tugur, HIND.

A straight middling sized tree in the gardens at Kotah; the tree is sacred, and the wood is scented and used in incense.—*Genl. Med. Top. p.* 186.

(8032) TABERNÆMONTANA RECURVA. RECURVED TABERNÆMONTANA. This is a low shrub indigenous about Maulmain, remarkable for its recurved peduncles and fragrant flowers. —*Mason.*

(8033) TABLE-CLOTHS. This manufacture is carried on at the towns of Cuddalore, Chingleput, and in the outskirts of Madras, and are equal in quality to those of English manufacture. They are of different sizes, the largest 9 cubits in breadth and 15 in length and 12 cubits long by 6 broad, the smallest 9 by 4. They are sold at different rates. The Table cloths and Napkins of Pondicherry from the works of Monsieur R. Godfroy are very good in quality, varying in size from the ordinary table cloth to those of dimensions suited to public entertainments. The Madras Exhibition Jury expressed their unqualified approbation of this fabric, made with thread and wove, with machinery set up by the enterprising firm connected with this manufacture in this country. The design, now commonly called the Damask pattern, and imitated in various parts of the Madras Presidency, was introduced at these works. The Jury desired to bring this manufacture to the especial notice of the Committee of the Madras Exhibition and awarded a 1st Class Medal.—*M. E. J. R.* Polar Chetty exhibited the finest quality of wove Table Cloths and Napkins made at Madras, the Jury awarded him a 2nd Class Medal.—*M. E. J. R.*

(8034) TACAMAHAC. A resin obtained from the *Fagara Octandra*; and likewise, it is supposed, from the *Populus balsamifera* It is imported from America in large oblong masses wrapt in flag leaves. It is of a light brown colour, very brittle, and easily melted. When pure it has an aromatic smell, between that of lavender and musk; and dissolves completely in alcohol, water having no action on it. *Thomson's Chemistry.—Faulkner.*

(8035) TACCA, a genus of Plants belonging to the natural order *Taccaceæ*, placed near *Aroidaceæ*, and *Aristolochiaceæ*, and resembling *Dioscoreaceæ*, in having radical tubers which abound in fæcula. The genus is named from the Malay name of one of the species, which are found in the hotter parts of India and in the South Sea Islands. The genus is characterised by having a 6-partite calyx, with a 6 partite corolla, and 6 stamens which are inserted in the calyx: styles 3; stigmas stellate. Very dry, hexangular, many-seeded. The plants have perennial tubers, with a short compressed rhizoma, from which proceed the stalked and the so-called radical leaves and herbaceous scapes. The plants of this family are possessed of some acridity both in their tubers and in their herbaceous parts, but the roots lose some of this quality by culture, at the same time that they become larger. Those of *T. pinnatifida*, the best-known species, and a native of the Malayan Peninsula, the Moluccas, Madagascar, and Australia, are roundish, red, the size of a man's fist, extremely bitter, and acrid. The tubers of this plant, and also those of *T. dubia* and *T. montana*, are rasped and macerated for four or five days in water; a white highly nutritious fæcula like arrow-root is then separated, and, like sago, is employed as an article of diet by the inhabitants of the Malayan Peninsula and the Moluccas. In Tahiti and some of the Society Islands they make cakes of the tubers of *T. pinnatifida*, which are the Tacca Youy of some navigators. They form an article of diet in China and Cochin-China, and also in Travancore, in India, where, according to

Dr. Ainslie, they attain a large size, and the natives eat them with some acid to subdue their acrimony. (Royle's 'Illustr.,' p. 378.) The petioles and stalks boiled for some time are also used as articles of diet in China and Cochin-China. In Tahiti the plant is called Tya: its fæcula is largely prepared, and is sometimes preferred to that of Maranta arrow-root by the English, to whom it is sold under that name by the native converts at the missionary station, and exported to London. It is also sometimes called Tahiti Salep. This plant must not be confounded with the *Arum macrorhizum*, the tuberous root-stalk of which is also edible, and when prepared is called Taka,, which similarity in name and in uses has frequently caused confusion, and the mistaking of one plant for the other. In Singapore *T. cristata* is called Water-Lily.—*Eng. Cyc.*

(8036) TACCA PINNATIFIDA Lin.

Cara Carnay kalung, Tam.	Tacca, also Leeker, Malay.
Kunda, Duk.	Soorana, Sans.
Cunda gudda. Tel.	
Toja, Bunda.	

This root, says Ainslie, appears to be eaten in many Eastern countries, such as China, Cochin-China, and Banda, in which last mentioned, where sago is scarce, it is in common use. In Otaheite and other Society isles, they make, of the meal of it, a nourishing gelatinous cake, like that made of salep. It possesses a considerable degree of acrimony, and requires frequent washing in cold water previously to its being dressed. In Travancore, where this root grows to a very large size, and is called Chanay kelengu, it is much eaten by the Natives who are in the habit of mixing a sufficient portion of some agreeable acid with it, to subdue its natural pungency.—*Ainslie p.* 248. See Arrow Root, also Food, also Maranta.

(8037) TACCACEÆ, a small natural order of Endogenous Plants belonging to the Epigynose group. There are but two genera belonging to this order, *Tacca* and *Attaccia*. The species are large perennial herbaceous plants, with a tuberous root, a short stem bearing scapes, and having exstipulate radical pedatifid pinnatifid rarely entire leaves, with curved parallel veins. The flowers, which are placed on the top of a single scape, are in umbels, and are united; the tube of the perianth is superior, and united to the germen; limb petaloid, equal or unequal, persistent; stamen 6; filaments dilated; ovary composed of 3 connected carpels, with 5 parietal polyspermous placentæ; styles 3, connate. The fruit baccate, with seeds lunate, striated, and the embryo situated on the outside of fleshy albumen.—*Eng. Cyc. p.* 1004.

(8038) TACSONIA PINNATISTIPULA. Passifloraceæ. These are climbing plants nearly allied to the Passion Flowers, and require the same treatment. Colors rose or pink.—*Riddell.*

(8039) TADAH WOOD.

Tadda, Tel. | Kakatatee, Tam.

(8040) TÆNIS BLECHNOIDES, Tai worm fern. The tapeworm fern, so called fr the resemblance of the line of sori to a ta worm, is not infrequent in Tenasserim.—*Mas*

(8041) TAGETES ERECTA, Tall Mai gold.

Geuda, Hind.

A great variety in gardens.—*Gen. Med. T p.* 206.

(8042) TAGETES LUCIDA, Composit African Marigold. This is common in all g dens, and readily grown from seed.—*Riddell.*

(8043) TAGETES PATULA, Fren Marygold.

Gool-jafare, Hind.

Common in gardens.—*Gen. Med. Top. p* 206.

(8044) TALAUMA HODGSONI, a magn lia growing on Tonglo in Sikkim at an elevati of several thousand feet. It is a large tr with very dense foliage, and deep shining leav a foot to eighteen inches long, most of its flo ers drop unexpanded from the tree and diffus very aromatic fragrance: they are nearly large as the fist, the outer leaves purple, inner pure white.—*Hooker, Him. Journ. Vol page* 163.

(8045) TALC.

Kobub ul arz, Arab.	Abruck, Tulk, G Hind.
Minirum, Cyng.	Talcum, Lat.
Tulk Cash.	Tulk. Pers.
Tulk, Duk.	Abraka, Sans.
Talc, Fr.	Tilk, Turk.
Talk, Ger.	
Appracum, Tam. Tel.	

Talc is one of the hydrous silicates of mag sia. It occurs *crystallized* and *massive*. primary form of the crystal is a rhomboid, it usually occurs in the secondary form of he gonal laminæ, and even in long prisms. cleavage is distinct and perpendicular to axis. It is readily separable into thin pla which are flexible, but not elastic. The lus is pearly, and the colour a shade of light gr or greenish white: sometimes it is silvery-wh and also greyish-green and dark olive green. is unctuous to the touch, and is easily impres by the nail,—the hardness being equal to 1 1.5: the density varies from 2·7 to 2·9. Crys lized talc occurs in small quantity in serpent rocks, accompained by carbonate of li actinolite, steatite, and massive talc, &c. massive varieties occur in beds of mica ous schist, gneiss, and serpentine. Mas talc or soap-stone reduced to powder fo what is called *boot-powder* or Bootmaker's d dusting the inside of a tightly fitting boot v this substance to enable it to be drawn on eas

This substance was largely used some years ago at Manchester, as one of the ingredients for converting an inferior low-priced tea into a high-priced one. The manufacturers of boot-powder, surprised at the large demand for their article by one house, and that house a tea-ware-house, made some inquiries, which led to sufficient publicity to put a stop to the fraud.—*Faulkner. Tomlinson. Talc or Mica*, has been used as a substitute for glass, in the taking of Collodion Pictures, the Collodion film adheres to it very firmly. On it Negatives can be as easily carried, without injury, in a portfolio, as on paper, and positives backed with color, and a plain varnish can be pasted, without risk of deterioration in a book. The mica being attached to a piece of glass by its back being moistened, may be then coated, exposed and developed, after which it may be detached and fixed. Talc mines abound in Bengal: upwards of a thousand maunds or nearly forty tons are sent to Calcutta annually, of the value of seven thousand five hundred rupees, at seven and half rupees per maund. —*Friend of India.*

Indurated talc occurs in primitive mountains, in clay-slate, and serpentine; it is massive, of a greenish-grey colour; the structure schistose and curved; it is of a shining and sometimes pearly lustre; translucent, soft and rather unctuous to the touch, and of the sp. gr. 2.9. Lamellar talc contains, according to Vauquelin, silica 62 per cent. magnesia 27, alumina 1.8, oxide of iron 3.2 and water 6. Nearly allied to mica, are steatite, chlorite, and other magnesian minerals. —*Eng. Cyc.*

Talcose slate resembles mica slate [See MICA], but has a more greasy feel from its containing talc instead of mica. It is of a light-grey or dark-greyish brown colour; it breaks into slabs, which are used for fire-stones. *Talcose rock* is a kind of quartzose granite, containing more or less talc: it is intersected by veins of white quartz, and also contains chlorite. "The talcose rocks," says Dana, "are, to a great extent, the gold-rocks of the world. This rock contains the topaz of Brazil, and also euclase, and many other minerals."—*Tomlinson.*

(8046) TALIPOT TREE. CORYPHA UMBRACULIFERA, is one of five species of a genus of palms, all inhabitants of Asia. The Talipot tree grows in stony parts of the mountains of Ceylon, Malabar and the Malay coast. Its leaves are of gigantic size, the petiole being seven feet long, the blade six feet long and thirteen broad. The out spread leaf affords shelter for seven or eight persons. They are extensively used by the Cingalese as umbrellas and some of their records are written with a style on pieces of the blade of this palm.—*Seeman.*

(8047) TALLOW.

Shahum, ARAB.	Pech, PERS.
Hurruk tail, CYNG.	Sato, Toplenoe, RUS.
Suif, FR.	Sebo, &c. PORT.
Talg, GER.	Maat Kolupoo, TAM.
Churbee, GUZ. HIND.	Passarum kowoo, TE.
Sevo, IT.	Govapa, SANS.
Lemakchair, MAL.	

Animal fat melted and separated from the fibrous matter mixed with it. It is procured chiefly from oxen and sheep. Its quality depends principally on the care taken in purifying it, and also to a certain extent from the animal from which it is obtained. Tallow is an important article of trade, being used in the manufacture of candles, soap, in the dressing of leather and in various other processes of the arts.—*Faulkner.*

(8048) TAL MAKHANA. The seed of the plant comes from Shekhawattee to Ajmere: a stimulant, used in general debility, but chiefly as an aphrodisiac.—*Genl. Med. Top. p.* 152.

(8049) TALPIDÆ, a family of Animals belonging to the order *Insectivora*, and including the Moles. The genus *Talpa* of Linnæus, as it stands in the 12th edition of the 'Systema Naturæ' between the genera *Didelphis* and *Sorex*, comprises two species only, *Talpa Europæa*, the Common Mole, and *T. Asiatica*.—*Eng. Cyc.*

(8050) TAMARICACEÆ, *Tamarisks*, a small natural order of Plants, belonging to the syncarpous group of Polypetalous Exogens. The species are either shrubs or herbs, having rod-like branches with alternate entire leaves, resembling scales; the flowers are in dense spikes or racemes. The clayx is 4-5 parted, persistent the petals inserted into the calyx, both with imbricate æstivation; stamens hypogynous, distinct or united, equal in number with the petals or twice as many; ovary superior, with a short style and 3 stigmas; fruit a capsule, 3-valved 1-celled, with numerous seeds, which are comose; embryo straight with an inferior radicle. The species are found only in the Old World; the greatest number being met with in the basin of the Mediterranean. The plants of this order are innocuous and all are more or less astringent and their ashes after burning are remarkable for possesing a large quantity of sulphate of soda. *Myricaria germanica* is recommended as a diuretic.—*Eng. Cyc.*

Dr. O'Shaughnessy tells us that this well known order occurs in many parts of the world chiefly in hot and sandy districts adjacent to the sea or great rivers. Dr. Roxburgh describes two in India, the *Tamarix indica* (probably identical with *T. gallica*) and *dioica* (*jhuo*). The *T. Furca* occurs in the drier parts of the Doab, and in the neighbourhood of Delhi, where it is called *Asul* or *Atul* as in Arabia; other species are also found in the peninsula.

The Tamarices are bitter and astringent. In Denmark they are used instead of hops for mak-

according to Dr. Royle, they are on this account used in medicine by the native doctors of India. The same property also renders them valuable in dyeing. Other Indian species of the Tamarisk produce galls, which are used for the same purposes as those of *T. Indica.*—*Eng. Cyc.* It is a tree of considerable size, common in the Ajmeer district, but the wood is very inferior.—*Irvine.* In the Dekhan it is a small tree or shrub; grows abundantly in the beds of many rivers, and affords great shelter for all sorts of game.—*Riddell.* Tamarix Indica grows in the Punjab and in Cashmere. The galls formed on it are officinal, and are exported from Cashmere.—*Thirty-five years in the East by Dr. Honig. p.* 355.

(8058) TAMARIX ORIENTALIS, the Eastern Tamarisk, is a tree attaining a height of from 10 to 20 feet; it is glabrous all over, with minute, distant, sheathing, mucronate leaves, with slender lateral spikes of flowers, and a 4-valved capsule. This tree is a native of Arabia, Persia, and the East Indies, and is one of the largest and most elegant of the species of the Tamarisk. One of the finest specimens of this tree existing is at Babylon.—*Eng. Cyc.*

(8059) TAMBRA-BIJ. Seed of a small plant from Harowtee; stimulant.—*Gen. Top. p.* 153.

(8060) TANARIUS MAJOR.

Lacca Tree, ENG. | Laka, MALAY.

A tree with a red coloured wood, a native of Sumatra, used in dyeing and pharmacy. It is an article of considerable native trade, and is chiefly exported to China.—*Crawfurd, p.* 204.

(8061) TANNING MATERIALS. The manufacture of leather in India generally, is by no means so thriving as it might be, considering the great abundance of Tanning materials at command. This is probably owing to the very low rank of the Artisans (*Chucklers*), for the art of leather production is well understood and successfully practised by the European tanners at Pondicherry, Hoonsoor, Guntoor, Bangalore and Madras, the leather being scarcely inferior to that made in Europe.

Goat skins, Sheep skins, Buffalo and Bullocks' Hides are much used and are generally procurable, but are very badly dressed, as may be readily imagined from the excellent description of the usual process given by Mr. Rohdes, which accompanied the consignment of leather from Guntoor, currying the leather being the province of the wife, while manufacturing it for the market belongs to the husband. Inferiority of Indian leather may be ascribed to want of skill on the part of the currier, and the use of quicklime.

It is generally supposed that there is no better tanning material than Oak bark—but it has been shown in the article Leather (See LEATHER) that similar substances may be employed with great success, as for instance, Divi Divi, Catechu, Tanghedu Bark, &c., which produce their effect m rapidly, and the leather so manufactured is saic be nearly as durable. At the Madras Exhibit of 1855, a valuable series of Tanning mater accompanied the leather prepared by Mr. B den at Guntoor, and some interesting samp were shown from the Government Tanne Hoonsoor, with hides tanned by the differ barks, to illustrate the practical application these various substances.—*M. E. J. R.* The tract procured from the bark of the Butea; t of the Buchanania latifolia; the Syzygium Ja bolana &c. are of much consequence to Tanne —*Spry's Sug. p.* 67. Several species of Acac Conocarpus, the gum of the Dhak and others also used.—*Royle's Productive Resources of Ind* The rose-coloured fruit of the tamarind gi beautiful deep red-colour, approaching purp The wood of the *Adenanthera pavonina* dyes r and the wood of the black varnish tree afford red dye.—*Mason.* The extract procured fr the bark of the Butea, that of the Buchanai latifolia, the Syzygium (Calyptranthes), Jaml lana, &c. are likely to be of consequence to tanners, and could be produced in India in la quantities. Specimens of these and of the b of the Saul tree, of Nyctanthes arbor tristis, T minalia angustifolia, and of the "*gaub*" fr (Diospyros glutinosa), were shown by the E India Company at the Exhibition of 1851. *Simmonds' Comml. Products, p.* 494.

The following are the principal of the su stances of Southern and Eastern Asia, whi are or may be used in Tanning.

Babool bark,.....	Acacia arabica.
Catechu, cutch,.....	Acacia catechu. Fruit Acacia vera.

" "	Nyctanthes arbor-tristi
" "	Diospyros glutinosa.
Petals of.....	Hibiscus Rosa-Sinensis

The Tenasserim Provinces are rich in materials for tanning. It is there that the bark of the Careya, and of half a dozen different species of mangrove, the fruit of the sea-cocoanut, and the peel of a species of ebony, all abound in tannic acid. The principal sources are,

Rhizophora conjugata.
Rhizophora gymnorhiza.
Bruguiera Rheedii.
Bruguiera eriopetala.
Bruguiera parviflora.
Carallia lucida.
Kandelia Rheedii.—*Mason.*

The bark of Bauhinia variegata, is made use of as a tanning substance in Sinde and other parts of Asia. The bitter astringent bark and the galls of several of the Tamarisk tribe are also well suited for the purpose. The bark of the Cassia auriculata, and the milky juice of the Asclepias gigantea, are used for tanning in India. —*Simmonds' Comml. Product, p.* 493 *and* 494.

Tannin.—The substance from which pure tannin is most frequently obtained for chemical purposes is nutgalls, for tannin constitutes above 40 per cent. of their weight. It may however, as above shown, be procured from several other sources, such has oak, horse chestnut, sumach, and cinchona barks, catechu, kino, &c. The basis of the skins of animals is composed of a substance to which the name of gelatine is given. One of the properties of this substance is, that when combined with tannin, it forms the compound of tannate of gelatine, or leather, a substance which is so useful to mankind. From time immemorial, the substance employed in Britain, to furnish the tannin to the hides of animals, in order to convert them into leather, had been oak bark. But as the purpose for which oaks are grown there, is their timber, and not their bark, the supply of oak bark cannot be calculated upon, and this is, perhaps, one of the causes why tanning as an art is in such a backward state. The consumption of tannin required in the leather manufacture may be estimated from the fact that more than 672,000 cwts. of raw hides were imported into England in 1851, besides the hides of the cattle, &c., consumed in the United Kingdom. On the Continent of Europe and in the United States, the consumption of bark for this purpose is also considerable. The imports into England, of bark for the use of tanners and dyers has amounted yearly to the very large quantity of 380,674 cwt., besides what England obtains at home. Oak bark contains usually the largest proportion of tannin, and according to Davy's experiments eight-and-a-half pounds of oak bark are equivalent, for tanning purposes, to two-and-a-quarter of galls, three of sumach, seven-and-a-half of Leicester willow, eleven of Spanish chesnut, eighteen of elm, and twenty-one of common willow bark. Tannin obtained from these sources, however, differs materially in some of its characters. The tannin of gall-nuts, which is that generally employed for chemical purposes, is sometimes called gallo-tannic acid, to distinguish it from other species. Notwithstanding the number of different substances which have from time to time been introduced for the use of tanners, it is, nevertheless, pretty generally acknowledged that there is nothing superior, or even equal, to good oak bark, and that all attempts to hurry the leather-making process beyond a certain point by the use of concentrated solutions of tan, &c., are for the most part failures, as the manufacture of good leather, to a great extent, depends on the process being conducted in a slow and gradual, but—at the same time—thorough and complete manner. Oak bark is, however, as we have already shown, by no means the only astringent bark well suited to the use of the tanner, and in various parts of the world other similar substances are used with very great success. All these tanning materials, though they may not be considered by the English tanner equal to the best oak bark, are, nevertheless, of great value to him; they may be employed in conjunction with oak bark, or even as a substitute in times of scarcity, or when the price of oak bark is high; in fact the very existence of such substances tends to keep down and equalise the price of bark, and to prevent it from undergoing those great fluctuations in value which would necessarily occur were it the only tanning material available to our manufacturers.—("*Prof. Solly in Jury Reports of Great Exhibition.*")

The vast number of barks and other substances useful for tanning purposes, which are found in the tropics, are comparatively unknown or little regarded in Europe; although they might be readily obtained in large quantities and at a trifling cost. The bark of many species of *Acacia* furnishes the tanning principale in a great degree, particularly that of *A. arabica*, which, under the name of Babul wood, is largely used all over India; where it is regarded as a powerful tonic. The fruit of *A. vera*, termed Egyptian and Senegal "bablah," has been employed in tanning and dyeing. Numerous species of this tribe are found abundant in New South Wales and the Cape Colony, and these, particularly the Wattle bark of Australia, are in common use for tanning, from their astringent properties. The bark and rind of the fruit of the pomegranate (*Punica Granata*) have similar properties. The bark of *Avicenna tomentosa* is in great use in the Brazils for tanning. So are the curved pods of *Cæsalpinia coriaria* in the East and West Indies under the name of Divi-divi. *Coriaria myrtifolia* is not only used in tanning leather, but also for staining black. It is worth £9 to £10 per ton. *Pterocarpus marsupium* furnishes about Tellicherry the concrete exudation called kino, a

powerful astringent used for tanning. The plants of the mangrove tribe, *Rhizophora Mangle*, and other allied species, have frequently an astringent bark, which is in many cases used for tanning and dyeing black. This tree is very common in most tropical countries, where it forms dense thickets on the muddy banks of rivers and the sea shores. The bark of *Bauhinia variegata*, is made use of in Scinde and other parts of Asia. The bitter astringent bark and the galls of several of the Tamarisk tribe are also well suited for the purpose.

Mesembryanthemum nodiflorum, one of the numerous indigenous species of the Cape, is used in making morocco leather.

The extract procured from the bark of the *Butea*, that of the *Buchanania latifolia*, the *Syzigium* (*Calyptranthes*), *Jambolana*, &c., are likely to be of consequence to the tanners, and could be produced in India in large quantities. Specimens of these, and of the bark of the Saul tree, of *Nyctanthes arbortristis*, *Terminalia angustifolia*, and of the gaub fruit (*Diospyros glutinosa*), were shown by the East India Company. The bark of the hemlock tree is extensively employed for tanning in New Brunswick.

The bark of yellow hercules (*Xanthoxylum ochroxylon*), and the pods of *Acacia tortuosa* are used for tanning in the West Indies.

In the instructions given by the Admiralty to Sir James Ross, when proceeding on his Antarctic Expedition, his attention was particularly called to the astringent substances adapted for tanning, and to the various extracts of barks, &c. imported into England from our Australian settlements, and which are employed by the tanner. Little sterling information has as yet been obtained as to the qualities of the astringent gums, barks, and dyes, yielded in such abundance by the trees of those colonies, and the proportion of tannin they contain. In 1846, 563 tons of bark for tanning were exported from Port Phillip. A large quantity of tannin is extracted from various species of Eucalyptus, the gigantic gum trees in Australia and Van Diemen's Land (of which quarter all the species are natives), and sent to the English market; it is said to be twice as powerful in its operations as oak bark. Some of these trees attain a height of 200 feet. Their bark separates remarkably into layers. A sort of kino gum, an astringent resinous-like substance, is also extracted from *E. resinifera*, the brown gum-tree of New Holland, which is sold in the medicine bazars of India. It exudes in the form of red juice from incisions in the bark. A single tree will often yield 60 gallons. In Brazil they use the bark of *Luhea panicata*, an evergreen climber, for tanning leather; and in Peru the bark of some species of *Weinmannia* serves the same purpose. Among other powerful astringents may be noticed the root of a species of Sea Lavender (*Statice Caroliniana*), *Myrica cerifera*, and *Heuchera Americana*, all natives North America. Also the petals of *Hibis Rosa-sinensis*, a native of Asia. The sea-side gr (*Coccolaba uvifera*) yields an astringent substa known as Jamaica kino. The bark of the *Cas auriculata*, and the milky juice of the *Asclep gigantea*, are used for tanning in Ind The black mangrove (*Rhizophora mangle*) i tree attaining an altitude of from 30 to 50 fe and occupying marshy situations in t vicinity of the sea. Almost every part of t mangrove—the bark, roots, and the fruit m particularly—abounds in an astringent prin ple, which is successfully applied to the pu poses of tanning. As the tree is so abunda within the tropics, it might be worth the wh of some practical speculator, to make an e tract on the spot, and introduce it into t English market, for the use of tanners a dyers. For tanning, the mangrove is said be infinitely superior to oak bark, completi in six weeks an operation which with the l ter occupies at least six months, and the so leather so tanned is said to be more dural than any other. The bark and leaves, whi contain nearly as much tannin as the oak, a made use of in the West Indies, as well as Sinde and other parts of Asia. 3,713 pie of mangrove bark, valued at £819, were shi ped from Shanghae, one of the Chinese por in 1849. See MANGROVE also RHIZOPHORA.

Myrobalans.—This is a name applied to the a mond-like kernels of a nut or dried fruit of whi there are several sorts known in the East. Th are the produce of various species of *Terminali* as *T. Bellerica*, *chebula*, *citrina*, and *angustifoli* They vary from the size of olives to that of g nuts, and have a rough, bitter and unpleasa taste. Many of the trees of this tribe, which a all natives of the tropical regions of Asia, Afri and America, are used for tannin, and some f dyeing. They are highly valued by dyers, cre ing, when mixed with alum, a durable dark brov yellow. Myrobalans fetch in the Bombay ma ket 8s to 26s. the Surat candy of 821 lbs. T bark and leaves of *T. Catappa* yield a black pi ment, with which Indian ink is made; the see are eaten like almonds. A milky juice is sa to flow from *T. angustifolia* which when drie is fragrant, and, resembling Benzoin, is used a a kind of incense in the Catholic churches in t Mauritius. The fruit of *T. Bellerica*, and of *Chebula*, both useful timber trees, indigenous t the East Indies, are used medicinally as a ton and astringent. 117 cwts of myrobalans we shipped from Ceylon in 1845. The annual im ports of myrobalans into Hull, amount to abo 1,600 cwts. The quantity which arrived Liverpool was 185 tons in 1849, 851 tons i 1850; 27,212 bags in 1851, and 19,946 bag in 1852; they come from Calcutta an Bombay, and are also used for dyeing yellow an

black. The price in January, 1853, was 6s. to 12s. per cwt. The average annual imports into the United Kingdom may be taken at 1,800 tons.

Kino.—The Kino of commerce is the product of several trees (*see* KINO). The Kino of Botany Bay and Van Diemen's Land is the produce of the Iron Bark tree, *Eucalyptus resinifera*. White (Jour. of a voyage to N. S. Wales) says, this tree sometimes yields, on incision, 60 gallons of juice. Kino is imported in Boxes. That chiefly used as East Indian kino, is an extract formed by inspissating a decoction of the branches and twigs of the gambier plant. Vauquelin analysed it, and found it to consist of, tannin and peculiar extractive matter, 75; red gum, 24; insoluble matter, 1. The East Indian kino, imported from Bombay and Tellicherry, is the produce of *Pterocarpus marsupium* a lofty, broad-spreading forest tree, which blossoms in October and November. The bark is of a greyish color, and is upwards of half an inch in thickness on the trunk. When cut, a blood-red juice speedily exudes and trickles down; it soon thickens, and becomes hard in the course of fifteen or sixteen hours. The gum is extracted in the seasons when the tree is in blossom, by making longitudinal incisions in the bark round the trunk, so as to let the gum ooze down a broad leaf, placed as a spout, into a receiver. When the receiver is filled it is removed. The gum is dried in the sun until it crumbles, and then filled in wooden boxes for exportation. Another species, *Pterocarpus erinaceus*, a tree 40 to 50 feet in height, a native of the woods of the Gambia and Senegal, furnishes kino, but none is collected in or exported from Africa. *Butea frondosa*, or the dhak tree of the East Indies, furnishes a similar product, in the shape of a milky, colored, brittle, and very astringent gum. Some specimens of Butea kino, analysed by Prof. Solly, after the impurities had been separated, yielded 73¼ per cent. of tannin. See RHUS.

(8062) TANPING. There is imported into Shanghae from the north of China, a great quantity of a dry paste, known, under the name of Tanping: the residuum or husk of a leguminous plant called "Teuss," from which the Chinese extract oil, and which is used after being pressed as manure for the ground.—*Simmonds.*

(8063) TANSY. Tanacetum vulgaris and *var.* crispum. The young leaves cut small, are used in coloring and flavouring puddings, omelets, cakes, &c. The curled *var.* T. cripsum in garnishing; succeeds on the plains of India, and grows freely in any good soil.—*Jaffrey.*

(8064) TAPIOCA, a form of STARCH, prepared in South America from two species of *Janipha*, or the *bitter* and *sweet cassava* or *manioc* roots. From the facility with which the bitter cassava can be rasped into flour, it is cultivated almost to the exclusion of the sweet variety, which contains in its centre a tough fibrous ligneous cord, which is absent in the bitter variety. The latter, however, contains a highly acrid and poisonous juice, which is got rid of by heat or by fermentation, so that the cassava bread is quite free from it. When the juice has been carefully expressed, the fecula or flower is washed and dried in the air without heat, and forms the Brazilian Arrow-Root of commerce; but when dried on hot plates it becomes granular and forms Tapioca. An artificial Tapioca is made with gum and potato starch. The granules of this are larger, whiter, and more brittle and more soluble in cold water than genuine tapioca. —*Tomlinson.* At the Madras Exhibition of 1855, Tapioca was exhibited by Mr. Rundall, of Razole near Rajahmundry, which in respect of feel and taste was excellent. It is manufactured by him at the rate of Rs. 7 8 0 per maund. Various other samples of Miscellaneous "Hill Tapioca" were exhibited—obtained from the roots of different species of Arum, Dioscorea or Terrestrial Orchids: none of them appeared important, and from deficiency of exact information, the jury were unable to enter into details, *Amorphophallus campanulatus* (Telinga Potatoe,) esteemed a very wholesome food, was likewise exhibited from Travancore, under the name of "karna kelungoo"—The large dark coloured flowers have a very curious appearance.—*M. E. J. R. Tapioca*, of late years, has been prepared in various parts of India of a superior quality from the roots of the *Jatropa manihot.*—*Faulkner.* See ARROW ROOT, also CASSAVA, also JANIPHA, also IATROPHA, also FOOD.

(8065) TAPIRUS, *Tapir*, the name of a genus of Animals belonging to the family *Pachydermata*. *Tapirus* has the following generic characters: —Molars presenting on their crown before they are worn two transverse and rectilineal tubercles (collines); nose terminated in a small moveable proboscis, but not terminated with an organ of touch like that of the Elephant; neck rather long; skin rather thick, and covered with hair, looking as if it had been close shorn; two inguinal mammæ. Anterior feet with four toes; posterior feet with three toes. The species are found in Asia and America. The dental formula of the Asiatic species is as follow:—

$$\text{Incisors}, \frac{6}{6}; \text{ Canines}, \frac{1-1}{1-1}; \text{ Molars}, \frac{7-7}{6-6} = 42.$$

(8066) TAPIRUS MALAYANUS. (*T. Indicus* of the French zoologists; Le Maiba, F. Cuv., 'Mamm.'), the Asiatic Tapir. "The Malay Tapir resembles in form the American, and has a similar flexible proboscis, which is six or eight inches in length. Its general appearance is heavy and massive, somewhat resembling the Hog. The eyes are small; the ears roundish, and bordered with white. The skin is thick and firm, thinly covered with short

hair. There is no mane on the neck, as in the American species. The tail is very short, and almost destitute of hair. The legs are short and stout; the fore feet furnished with four toes, the hind feet with three. In the upper jaw there are seven molars on each side, one small canine inserted exactly on the suture of the incisor bone, and in front six incisors, the two outer of which are elongated into tusks. In the under jaw there are but six molars; the canines are large; and the number of the incisors, the outer of which are the smallest, is the same as in the upper jaw. The general colour is glossy black with the exception of the back, rump, and sides of the belly, which are white, and separated by a defined line from the parts that are black." (*Raffles.*) The habits of this species in a state of nature are probably similar to those of the American Tapirs. In captivity, Major Farquhar describes it as of a mild and gentle disposition. "It became as tame and familiar as a dog; fed indiscriminately on all kinds of vegetables, and was very fond of attending at table to receive bread, cakes, or the like." Sir Stamford Raffles adds, that the living specimen sent from Bencoolen to Bengal was young, and became very tractable. It was allowed to roam occasionally in the park at Barrackpore, and the man who had charge of it informed Sir Stamford that it frequently entered the ponds, and appeared to walk along the bottom under water, and not to make any attempt to swim. Sir Stamford also states that the flesh is eaten by the natives of Sumatra. The individuals which have been exhibited in the Regent's Park Gardens have been very mild and gentle.—*Eng Cyc.*

(8067) TAR.

Goudron, Fr.	Smola gesta, Pol.
Theer, Ger.	Degot, Smola Shitkaja, Rus.
Catrame, It.	
Pix liquida, Lat.	Tjara, Sw.

A thick black, unctuous substance, obtained by burning pine and fir trees in a close smothering heap, with a channel through which the tar exudes. It is extensively used for resisting moisture on wood, rope, &c., and is consequently in great request as a marine store. It is largely made in Russia, the United States, and Sweden. —*Faulkner.* Tar is chiefly employed for marine uses. Tar water was long a celebrated remedy, in the treatment of some chronic diseases of the lungs.—*O'Shaughnessy, page* 618.

(8068) TARAXACUM OFFICINALE, Dandelion. *Syn.* Leontodon Taraxacum. A native of Europe and the Himalayas. The inspissated juice of the plant, the infusion, decoction, and extract of the root, are strongly bitter, and prove tonic and diuretic, in large doses aperient. It is a favourite, and we believe useful remedy in the old hepatic diseases of persons who have long resided in India, and returned to a cold climate. The dose of the extract is 3 to 10 grains, thrice daily. For formulæ for infusion and decoction, *see Pharmacopœia.—O'Shaughnessy, p.* 407.

(8069) TARE, Fitch, Vetch. A species of pulse (*Vicia sativa*). Cultivated in Great Britain principally for its stems and leaves, which are used in the feeding of sheep, horses, and cattle; and partly also for its seed, which is used in the feeding of poultry.—*Faulkner.*

(8070) TARINE A hard, fine, close-grained, rather heavy Ceylon wood, much resembling English birch.

(8071) TARSIUS. (Storr), a genus of Animals belonging to the family *Quadrumana.* It has the following characters:—Head rounded; muzzle short; eyes very large; posterior limbs very much elongated, with the tarsus thrice as long as the metatarsus. Tail long.

Dental formula:—Incisors. $\frac{4}{2}$; Canines, $\frac{1-1}{1-1}$; Molars, $\frac{6-6}{6-6}$ = 33

(8072) TARSIUS BANCANUS. Dr. Horsfield remarks, that although the *Tarsius* from Banca agrees in the essential points with the other species of this singular genus which have hitherto been discovered, it has no intermediate front teeth, and the exterior tooth on each side is, compared with other species, very minute. Counting (with Desmarest) one canine tooth on each side, above and beneath, it has, says Dr. Horsfield, only five grinders in each jaw. The hands of this creature are small and delicate, and externally covered with a very soft down. Internally they are naked. The nails of all the fingers of the hand, as well as of the thumb and the third and fourth finger of the feet, are triangular, and represent a delicate compressed scale: on the index and middle finger of the feet they are erect, sharp, compressed, slightly curved and not inaptly compared by Mr. Fischer to the thorns of a rose-bush, constituting one of the essential characters of this genus. The body is handsomely formed, and, as in the other species, somewhat contracted towards the pelvis; the lower extremities also have in general a similar character, but the tarsus has less of the extravagant length which is common to the other *tarsii.* The fur is remarkably soft to the touch; it is compressed, of a thick and very delicate wool, which envelopes the body, head, and extremities, forming a coat of an unequal surface, from which irregular straggling hairs project; at the root of the tail, and at the hands of both extremities, it terminates abruptly in the form of a ring. The general colour is brown, inclining to gray; on the breast, abdomen, and interior of the extremities it is gray, inclining to whitish; a rufous tint is sparingly dispersed over the upper parts, which shows itself most on the head and extremities; the naked parts of the tail near the root are considerably darker than the extremity. ('*Zoological Researches in*

Java.') Dr. Horsfield obtained this animal in Banca, near Jeboos, one of the mining districts, where, he says, it inhabits the extensive forests in the vicinity.—*Eng Cyc.*

(8073) TARTAR (CRUDE), ARGAL, ARGOL. ORGOL.

Wynsteen, DUT.	Tartaro volgare, IT.
Tartre-cru, Blanc et rouge FR.	Tartarus, LAT.
Roher Weinstein, GER.	Tartaro, PORT.
	Winnui kamen, RUS.
	Tartaro, SP.

An acidulous salt, which exists in the juice of the grape, and is deposited in wine casks in the form of a crystallized incrustation more or less thick, which is crude tartar or argol. It is either white, or red, according to the colour of the wine; the former is preferred as it contains fewer impurities than the red; but the properties of both are essentially the same. When good, it is thick, hard, brittle, and brilliant, with but little earthy matter. It is obtained from Florence, Naples, Sicily, and Cape of Good Hope, and is used in hat-making, gilding, dyeing, and in the preparation of tartaric acid. (*Waterston.*) —*Faulkner.*

(8074) TEA.

The leaf of an evergreen shrub, a native of China and Japan; it is also cultivated in Java, Assam, Brazil, and other places; but at present the chief commercial source of tea is China, whence it is exported to different parts of the world.—*Faulkner.*

The Honorable Mr. Morrison says that the limits of his work could not admit of a full description of the various sorts of tea, or an account of their preparation; nor would the most minute details enable any one to select good teas, or supply that skill which practice gives in discriminating their qualities. An account of the cultivation of the plant, and mode of curing the leaves, together with some information respecting the different varieties of black and green teas, the origin of the names and other particulars relating to its sale and consumption, is contained in the Chinese Repository Vol. VIII pages 132-164, to which he refers the reader. In the Tabular statement, the total exportation of tea is put down at 350,000 peculs or forty millions of pounds, but it is probably nearer 427,500 peculs, or fifty-seven millions of pounds; viz. to England, 40,000,000 lbs.; to the United States 14,000,000 lbs.; and to all other countries, 3,000,000 lbs. which at 25 taels per pecul, instead of the 20 in the Statement, amounts to 10,687,500 tales, or $ 14,500,000. The present duty of 2 5t. exclusive of all shipping and other charges, which were before included in the total sum of 5 taels paid the hong-merchant as duty.—*Morrison.*

Tea statistics.—The immense traffic in the produce of this simple shrub, the growth of a remarkable country, for long almost entirely isolated from the western nations, is one of the most remarkable illustrations of the enterprise and energy of modern commerce. The trade in tea now gives employment to upwards of 50,000 tons of British shipping, and about ten millions sterling of English capital, producing a revenue to Great Britain of nearly six millions sterling.

Tea, its properties.—Every reflecting man will admit that articles of such vast consumption as tea and coffee (amounting together to more than 348,500 tons annually), forming the chief liquid food of whole nations, must exercise a great influence upon the health of the people. There is scarcely any country in the world in which a dietetic drink or beverage resembling tea, is not prepared, and in general use from some exotic or indigenous shrub. The two chief plants laid under contribution are, however, the Chinese tea-plant, and a species of holly peculiar to South America producing the Paraguay tea. *Astoria theiformis* is used at Santa Fe as tea. The leaves of *Ceanothus Americanus*, an astringent herb, have been used as a substitute, under the name of New Jersey tea. It has been a matter of surprise why tea should be so much sought after by the poorer classes, since by many it is looked on more as a luxury than of use to the human system. The manner in which it acts, and the cause why it is so much in demand by all classes, is satisfactorily explained by Liebig; and the benefit, therefore, which will be conferred by selling it at a low rate, and thus placing it within the means of all, has at last come to be duly appreciated. Liebig says, without entering minutely into the medical action of caffeine, theine, &c., it will surely appear a most striking fact, even if we were to deny its influence on the process of secretion, that the substance, with the addition of oxygen and the elements of water, can yield taurine, the nitrogenised compound peculiar to bile:—

	Carbon.	Nitrogen.	Hydrogen.	Oxygen.
1 atom caffeine or theine =	8	2	5	2
9 atoms water..... =	...	...	9	9
9 atoms oxygen ..... =	...	...	...	9
= 2 atoms taurine...	8	2	14	20
=	2	4	9	10

Commerce in Tea.—The first tea imported into England was a package of two pounds, by the East India Company, in 1664, as a present to the king; in 1667, another small importation took place, from the company's factory at Bantam. The direc-

tors ordered their servants to "send home by their ships 100 pounds weight of best *tey* they could get." In 1678 were imported 4,713 lbs.; but in the six following years the entire imports amounted to no more than 410 lbs. According to Milborn's "Oriental Commerce," the consumption in 1711 was 141,995 lbs.; 120,595 lbs. in 1715, and 237,904 lbs. in 1720. In 1745 the amount was 730,729 lbs. For above a century and a half, the sole object of the East India Company's trade with China was to provide tea for the consumption of the United Kingdom. The company had the exclusive trade, and were bound to send orders for tea, and to provide ships to import the same, and always to have a year's consumption in their warehouses. The teas were disposed of in London, where only they could be imported, at quarterly sales. The act of 1834, however, threw open the trade to China. From a Parliamentary return, showing the quantity of tea retained for home consumption in the United Kingdom, in each year, from 1740 to the termination of the East India Company's sales, and thence to the present time, it appears that in 1740, 1,493,695 lbs. of tea were retained for home consumption. Two years afterwards, the quantity fell to 473,868 lbs. and in 1767 only 215,019 lbs. were retained. Next year the amount increased to 3,155,417 lbs.; in 1769 it was 9,114,854 lbs.; in 1795, 21,342,845 lbs.; in 1836, 49,842,236 lbs. The return in question also specifies the quantity of the various kinds of tea, with the average sale prices. According to the annual tea reports of Messrs. W. J. Thompson and Son, and Messrs. W. E. Franks and Son, the total imports into Britain of tea during the last fifteen years were as follows, reckoned in millions of lbs.:—

Years.	Black.	Green.	Total.	Home Consumption.
1838	26,786 ...	8,215 ...	35,001 ...	36,415
1839 ...	30,644 ...	7,680 ...	38,324 ...	36,351
1840 ...	21,063 ...	7,161 ...	28,224 ...	31,716
1841 ...	24,915 ...	6,303 ...	31,218 ...	36,811
1842 ...	31,915 ...	9,729 ...	41,644 ...	37,554
1843 ...	39,513 ...	7,340 ...	46,853 ...	39,902
1844 ...	39,644 ...	8,749 ...	48,393 ...	41,176
1845 ...	39,518 ...	11,790 ...	51,338 ...	44,127
1846 ...	44,017 ...	12,486 ...	56,503 ...	47,534
1847 ...	46,887 ...	8,368 ...	55,255 ...	46,247
1848 ...	37,512 ...	7,611 ...	45,123 ...	48,431
1849 ...	43,234 ...	9,156 ...	52,400 ...	50,100
1850 ...	39,873 ...	8,427 ...	48,300 ...	51,000
1851 ...	62,369 ...	9,131 ..	71,500 ..	54,000
1852 ...	55,525 ...	9,175 ...	64,700 ...	54,724

Duty.—In England, duty on tea was gradually raised from 9d. per lb. in 1787 to 3s. a lb. in 1806. It was 2s. 2d. per lb. until May, 1852, when 4d. per lb. was taken off, and further annual reductions are to be made. Down to the year 1834 the duty was an *ad valorem* one of 96 per cent. on all tea sold under 2s. a lb., and of 100 per cent. on all that were sold at or abo 2s., charged on the prices which they brought East India Company's sales. The *ad valore* duties ceased on the 22nd of April, 183 and under the act 3 and 4 William IV. 100, all tea imported into the United Kingdo for home consumption was charged with a cu toms duty as follows:—

Bohea	1s. 6d.	per lb.
Congou, twankay, hyson skin, orange pekoe and canpoi	2 2	„
Souchong, flowery pekoe, hyson, young hyson, gunpowder, imperial, and other teas not enumerated	3 0	„

In 1836, the uniform duty of 2s. 1d. per l on all descriptions of tea was imposed, whic with the additional 5 per cent. imposed in 184 made the total duty levied per lb. 2s. 2d. and fraction.

Cost of Tea.—The average cost of tea in Chi at the ship's side is 10d. per pound, while it is co fidently asserted that it could be produced in ma parts of America at 5d. the pound. The great co in China is owing to the expensive transportatic the cultivation of the fuel used, the absence all economy of machinery, &c. It is only adulteration that tea is sold in China as che as 10d. In America the heating and rolling the leaves (one half of the labor) could be do by the simplest machinery, fuel could be econ mised by flues, &c. The Russian teas broug by caravans, are the most expensive and b teas used in Europe. The Chinese themselves p 7½ dollars per pound for the "Yen Pouchong" te Full chests were exhibited in 1851, by Mr. Ripl of various Pekoe teas, some of which fetch 5 per lb. in the China market; whilst 7s. is t very highest price any of the sort will fetch England, and this only as a fancy article. T plain and orange-scented Pekoes now fetch lit with us; but all caravan teas are purchased the wealthier Russian families. The finest, ho ever, never leave China, being bought up by t Mandarins; for though the transit expenses a 3s. to 4s. per lb. to the value when sold in Ru sia, the highest market price in St. Petersbu is always under 50s. Among these scented te are various caper teas, flavoured with chloranth flowers and the buds of some species of plan belonging to the orange tribe, *Magnolia fusca* olea flowers, &c. The Cong Souchong, or Nin young teas, are chiefly purchased for the Ame can market. Oolong tea is the favourite dri in Calcutta, though less prized in England, delicate flavor being injured by the length the voyage. For delicacy, no teas, appro those usually called "Mandarin teas," which ing slightly fired and rather damp when in fittest state for use, will bear neither transp

nor keeping. They are in great demand among the wealthy Chinese, and average 20s. per lb. in the native market.—*Jury Report* of Ex. of 1851.

Consumption of Tea.—The consumption of tea in the United Kingdom may now be fairly taken at fifty-four million pounds yearly, and sold at an average price to the consumer of 4s. 6d., per pound. The money expended for tea is upwards of twelve millions sterling. The population of the Chinese provinces, as quoted by Dr. Morrison, from an official census taken in 1825, was 352,866,012, and we may fairly conclude that during the last twenty-eight years this population has extensively increased. If we multiply the population of China by four, we have—

	lbs.
Total consumption of tea in China	1,411,464,048
Export to Great Britain and Ireland, for the year ending June 30, 1851	64,020,000
Export to the United States, same period	28,760,800
Exported to Holland, returned at 2,000,00) in "Davis's China."	3,000,000
Inland trade to Russia	15,000,000
Export to Hamburg, Bremen, Denmark, Sweden, &c, seven cargoes, about	3,000,000
Export to Sydney, and Australasian Colonies, at least	6,000,000
Export to Spain and France, four cargoes	2,000,000
Total lbs.	1,533,244,848

The above is exclusive of the heavy exportation in Chinese vessels to all parts of the east where Chinese emigrants are settled, such as Tonquin, Cochin China, Cambodia, Siam, the Philippines, Borneo, and the various settlements within the Straits of Malacca. In comparison with such an enormous quantity, the 54 million lbs. consumed in the United Kingdom sink into insignificance.

	£
The cost of tea to America, at the ship's side in China, say 29,000,000 lbs., at an average of 1s. per lb, would be	1,450,000
The cost to England, 64,000,000, at the same price	3,200,000
The cost to other places, say 25,000,000	1,250,000
Russia, 15,000,000	750,000
Total	£6,650,000

Production of Tea.—It is important, in calculating what tea may be had from China, to consider the manner of its production. It is grown over an immense district, in small farms, or rather gardens, no farm producing more than 600 chests. "The tea merchant goes himself, or sends his agents to all the small towns, villages, and temp in the district, to purchase tea from the prie and small farmers; the large merchant, into whc hands the tea thus comes, *has to refire it a pack it for the foreign market.*'—(*Fortune's T Districts.*) This refiring is the only additional pr cess of manufacture for the Foreign market. M Fortune elsewhere, in his valuable work, givi an account of the cost of tea from the farme the conveyance to market, and the merchan profit, states that "the small farmer and ma pulator is not overpaid, but that the great pr fits are received by the middlemen."—*Simmon*

Habit. of Tea Plant.—Thunberg informs that the Tea-plant grows plentifully in Jap both in a wild and cultivated state, and I Wallich says that it is found in Coch China. I have met with it says Fortune in cul vation in China, from Canton in the south up the 31st degree of north latitude, and Mr. Reev says it is found in the province of Sham-tun near the city of Sang-chow-foo, in latitude 3(30' north. page 272. The principal tea distric of China, however, and those which supply t greater portion of the teas exported to Euro and America, lie between the 25th and 31 degrees of north latitude, and the best distric are those between 27° and 31°.—*Fortune's T Districts, page* 272.

Tea districts.—The tea districts in Chi extend from the 27th degree to the 31st degr of north latitude, and, according to missionari it thrives in the more northern province Kœmpfer says it is cultivated in Japan, as f north as 45 degrees. It seems to succeed bc on the sides of mountains, among sandstor schistus, and granite.—*Simmonds.*

The green-tea shrub is cultivated very exte sively in the interior of the island of Chusan.- *Fortune, page* 117.

Mauritius, Bourbon, St. Helena, Cape.- Mr. Boyer, director of the museum at Po Louis, Mauritius, has succeeded in rearing 40,0(tea-trees, and expresses an opinion, that if t island of Bourbon would give itself up to t cultivation, it might easily supply France wi all the tea she requires. The culture has al been commenced on a small scale, in St. Hel na, and the Cape Colony. The cultivation the tea-tree might be tried with probability success in Natal, and the Mauritius. The pla grows in every soil, even the most ungratefu resists the hurricanes, and requires little car The picking of the leaves, like the pods of co ton, is performed by women, children, and t infirm, without much expense. The preparatic is known to the greater part of the Chines of whom there are so many in Mauritius; b sides, it is not difficult. A Mr. Duprat h planted a certain extent of land in the neig bourhood of Cernpipe, in that island, but have not yet learnt with what success.

Cochin China.—The tea of Cochin China is considered inferior to that of China, being less strong and pleasant in flavour. An inferior sort of tea, with a leaf twice or thrice as large as that of Bohea, grows wild in the hilly parts of Quang-si, and is sold at from 12s. 6d. to 40s. the picul of 133 lbs.

Java.—The Dutch have devoted much attention to tea cultivation in Java, and the plantations are in fine order. Nearly a million lbs. of tea were shipped thence in 1848; but the tea is said to be of inferior quality, and grown and manufactured at considerable expense.

Japan.—Japan produces both black and green tea. The Japanese prefer the latter to the Chinese green tea. The black tea is very bad. The Japanese tea-tree, is an evergreen, growing in the most sterile places to the height of about six feet. It is described by Kœmpfer, as having leaves like the cherry, with a flower like the wild rose; when fresh, the leaves have no smell, but a very astringent taste. Tea grows in all the southern provinces of Japan, but the best green is produced in the principality of Kioto, where it is cultivated with great care.

Ceylon.—A few years ago, Messrs. Worms attempted the cultivation of tea in Ceylon. The Island, however, lies too far within the tropics to offer a climate like Assam, which is situate without them. The plants may thrive to appearance, but that is not a demonstration of their quality.

Pinang,—The tea-plant has reached upwards of six feet in height at Pinang, and in as healthy a state as could be desired, but the leaf had no flavor, and although thousands of Chinese husbandmen cultivated species, and other tropical productions on that island, no one thinks it worth while to extend the cultivation of the tea-plant in Pinang. The Chinese there laugh at the idea of converting the leaf into a beverage.

India.—Dr. Wallich mentions it in Cochin-China in N. lat. 17°, and in China in the southern provinces of Yunan and of Qung-tung. Mr. Reeves informed Dr. Royle that, in a Chinese Herbal, tea is said to be produced, among other places to the northward of 31°, in nine places in Hoo-Quang, three places in Ho-nan, one place in Shensi, and two places in Shantung; one of these latter, and the most northward of the whole, is Tangchow-Foo, in 36° 30' N. lat.—and in the Japan islands, which extend from 30° to 41° of N. lat., Dr. Abel states having found it in an apparently wild state at See-chou, in the province of Kiang-see, about N. lat. 26°, where the hills were covered with pines. Dr. Royle has, since the publication of his observations, seen an excellent specimen in flower in the British Museum, collected by another botanist (Mr. Cunningham) near Chusan, which is in 30° of N. lat. and where, he says, it delights on the tops of mountains like the pine. [This specimen was pointed out to Dr. Royle by Mr. R. Brown, distinguished as the first botanist of the day. The note attached to it is in the hand-writing of Cunningham. "Thea frutex flore alho rosaceo summitatibus montium gaudens uti pinus."—Herb. Mus, vol. xciii., fol. 146.] He further informs us, that "a plant was given to him at Suddiya, which he had reason to suppose was a genuine tea tree." Lieut. Charlton writes, on the 17th May, 1834, that he had been informed three years previously of the tea plants growing wild near Bheesa, whence indeed, he obtained three or four young trees, which he gave to Dr. John Tytler, to be planted in the Government Botanical Garden. On the 8th November, he sent to Calcutta some seeds and leaves of the tea trees of Assam, which were forwarded on the 24th December to the Government by the Tea Committee, who announced that "the tea shrub is beyond all doubt indigenous in Upper Assam, being found there, through an extent of country of one month's march within the Honourable Company's territories, from Suddiya and Beesa to the Chinese frontier province of Yunnan, where the shrub is cultivated for the sake of its leaf." So far back, however, as 1826, Mr. D. Scott sent from Munnipore, to Mr. G. Swinton, then Chief Secretary to the India Government, specimen of the leaves of a shrub which he insisted was a real tea. These we find were first discovered by Mr. Bruce, who was then in command at Suddiya. He sent tea seeds and plants to Mr. Scott, having been previously informed of their existence by his brother, the late Major Bruce; and he subsequently, in 1833, brought it to the notice of Capt. Jenkins.—(Tea Cultivation in India, p. 91.) Descriptions have been published by these gentlemen of the several tea tracts which they had at that time an opportunity of examining. These, according to Dr. Wallich, were five in number,—Koojo and Niggroo, among the Singpho, Nuddooa (Noadwar) and Tengrae, in the Muttuck country, and Gubroo, at the foot of the Naga Hills, in the territories of Rajah Purrendur Singh. The last, Dr. Wallich supposes, is connected with others to the southward, and with the tea plant originally announced as existing in Munnipore, and this, he says, may have originated from the plant at Hookum, and that all may have "originally travelled from the frontiers of China," where we know that a kind of tea is cultivated in the province of Yunan. Mr. Bruce, in his latest account, published in August 1839, in the Journal of the Asiatic Society, gives an account of the discovery of other tea tracts, which then amounted to no less than "one hundred and twenty, some of them very extensive, both on the hills, and in the plains." The hills on which tea has been found by Mr. Bruce, are the Naga Hills, and those of

Gubroo and Tipum.—*Royle's Productive Resources of India.* These discoveries were not lost sight of, and the Calcutta *Daily News* thus notices the half yearly report of the Assam Tea Company :—"The crop of Tea which in 1855 was 588,379 lb. and in 1856, 638,789 lb. is expected in 1857 to reach 700,000 lb. or nearly twenty times as much as the produce of the Government establishments in the North West in the fifteenth year of their existence. Nothing is said of the cost of the Tea ; but that was, we suppose, shewn in the accounts which were laid before the shareholders, but which have not been sent to us for publication. The whole of these Teas appear to have been hitherto shipped to England and those now arriving, will probably command extreme prices in consequence of the war with China. Should the notion be started at home that the Chinese may possibly medicate their Tea, there is no saying what prices may be paid for the Indian article, warranted genuine. The meeting by the secretary Mr. Elliot, read a letter from Dr. Jameson, Superintendant of the Botanical Garden at Saharunpoor, giving an account of the Tea plantations in the Himalayas. The encouragement given to the cultivation of tea in the last two years bids fair to render tea a staple article of produce in the N. W. Provinces. Last year the quantity turned out was 40,000 lbs. ; this year, that amount will be doubled. It is now in great demand at Almorah and Deyrah, the best kinds realizing from 3 Rs. to 4 Rs. 8 Annas per pound, and this not for small quantities, the amount disposed of having been 20,000 lbs. A great proportion of the second class teas was purchased by natives for the purpose of bartering with the Bhotiahs in the interior of the Himalayas and Thibet in exchange for Borax and other products of the Mountain region. Up to this time the Mountain races have been in the habit of consuming the brick teas of China. It is certainly a remarkable fact that an integral part of the Chinese Empire is receiving its supplies of tea from India, and Dr. Jameson is sanguine that if aided by good roads the trade with the Bhotiahs will soon become an important one, and that the Indian teas will be sold at rates so cheap as to drive the Chinese article out of the market in these regions.—*Calcutta Daily News*, 1857.

Introduction of Chinese plants into INDIA, *especially Assam and Himalayas.*—We have shown that it thrives equally well in the vicinity of Canton, and the milder climate of Nankin, as in the northern latitudes of Pekin and Japan ; embracing, therefore, a distribution over twenty degrees of latitude. The knowledge of this fact led to an inquiry in India, so long since as 1827, as to the practicability of introducing the culture of the tea-plant into the northern regions of that vast country ; and the result was an opinion of the Company's botanist, Dr. Royle, that it might be successfully grown in the north-western portion of the Himalaya districts. He pointed out some localities particularly suited to the experiment in the district of Kumaon, a portion of the province of Delhi, and situated between the 29th and the 30th degrees of north latitude, to the north-west of Nepaul. This opinion was afterwards backed by the investigations of others, who agreed in the belief that there was no impediment to the successful introduction of the tea culture in the Himalayan regions beyond the difficulty of obtaining a supply of plants, and some details relative to the Chinese mode of cultivation and curing of the article. In 1834 Lord William Bentinck formed a committee, with the view of adopting measures for attempting this cultivation in India ; and the first step taken was the dispatch of agents to the tea districts of China, whence a supply of seeds and plants, and much valuable information was brought. Nurseries were formed in Calcutta, and some ten thousand plants were reared, the greater portion of which were dispatched to Kumaon, though but a small fraction of them reached the Himalayas ; whilst a quantity was forwarded to the hill districts of the Madras presidency, but without any commercial results. The plants dispatched northwards were distributed in several directions, and so well did they thrive, that in the year 1838 many of them had produced seed, which was at once sown, and thus formed fresh nurseries.

In the meantime the existence of the plant in a wild state had been ascertained in the upper districts of Assam, one of the north-eastern provinces of the Bengal presidency ; and inquiries having been directed to it, evidence was not long wanting to shew that the plant was growing in not less than a hundred different tracts amongst the dense jungles of that country. In 1837, samples of tea, prepared from the wild plants of the Assam district, were forwarded to Calcutta, and favourably reported on. Observations and researches instituted in the Assam country went to shew that the district really possessed most of the requisites of soil, position, altitude, and climate. Some valuable reports upon the peculiarities of this district, and the results of a number of experiments in the culture of the indigenous plants, were published at intervals between 1837 and 1840 ; and from these it appears that the best seasons for the manipulation of the tea-crop are in March, May, and July. Every inquiry goes to prove that the greatest success has been attained whenever the culture has been attempted on hilly slopes, or in the vicinity of rivers, with a temperature ranging from 27° to 80° ; indeed, it appears certain that the latter consideration is of far more importance than that of soil. The China tea-plants introduced into Upper Assam by the instrumentality of the Company's servants

have not only thriven remarkably well, but attained a size and vigour unknown to them in their native soil. The first parcels of tea from these districts were highly approved of on their arrival in England, and realised enormous prices, partly owing, in all probability, to their novelty. The result of these sales, however, placed it beyond a doubt that the cultivation of tea could be profitably carried on in that part of India; and in consequence, a public company, entitled the "Assam Company," was formed for the purpose of carrying on the culture and manufacture of British Indian tea on an extensive scale. The East India Company having thus acted the part of pioneers, handed over their experimental plantations and establishments to the new company, who have since greatly enlarged the plantations and works, and have succeeded in producing a tea superior to any imported into this country from China, and equalled only by the fewer samples which, under the old company's system, used to be occasionally obtained. During the first years of their operations, the Assam Company encountered many obstacles, arising from the difficulty of procuring labour in sufficient quantity, from the want of skill of their first managers, and, above all, from the extreme remoteness of their property from all supervision. The formation of a Calcutta committee had obviated the latter evil, whilst the remaining difficulties have been successively overcome by patient perseverance: and the company is now on a most solid foundation, having increased their extent of plantation to twelve hundred acres, with a crop in 1853 calculated at 300,000 lbs., which has hitherto realised fully a third above the China teas. The produce of the company's tea-crop of 1847 realised 9,728*l.* nett; that of 1848, 12,552*l.*; that of 1849, 16,628*l.*; that of 1850, 18,153*l.*; and that of 1851, as above stated, 22,151*l.* The nett average price per pound in those years was, for 1847, 1*s.* 4*d.*; 1848, 1*s.* $5\frac{1}{16}$*d.*; 1849, 1*s.* $6\frac{13}{16}$*d.*; 1850, 1*s.* $6\frac{2}{16}$*d.*; and 1851, 1*s.* $8\frac{1}{2}$*d.*

In the Himalayan districts the labours of the tea experimentalists have been equally successful with those carried on in the more easterly province of Assam. About the year 1842, the aid of some of the Chinese cultivators, who had been introduced in the Assamese plantations, was obtained for tea-farms in the Kumaon district of the Himalayan country; and by their instrumentality a quantity of black tea was produced and dispatched to Calcutta, whence it was shipped to Great Britain, and pronounced superior in strength and flavour to the generality of Souchongs. By the end of the year 1844 these experimental plantations contained upwards of a hundred thousand plants; and two years later covered nearly two hundred acres, at various altitudes, varying from 2500 to 6500 feet above the sea-level. In the year 1848 this cultivation was still further extended, reaching to an extent of 1000 acres, not in one immediate neighbourhood, but stretching through many miles of country, and in some parts reaching the recently acquired Sikh territories on the north west frontier. The quantity of tea produced from these plantations must now be of some importance, and although the great distance of these districts from a port of shipment will always be a barrier to any successful competition with more favoured tea-producing countries, the supply of the local demand, already largely on the increase since this culture has commenced, will of itself prove a trade of no small value. So deeply impressed was the local government with the importance of this new branch of industry, that a grant of ten thousand pounds sterling a year was voted to carry out the experiment until it should, as in Assam, be taken up by private enterprise. In 1850 the East India Company, determined to lose no opportunity of fully testing the value of this cultivation, dispatched Mr. Fortune to China to glean all possible information regarding the tea-plant, its natural history, and the manipulation of its leaves; and, if possible, to bring away from the Chinese dominions a fresh supply of plants and seed of the best varieties, as also some experienced cultivators and work-people. In all these objects their agent was singularly fortunate, having but recently returned to India with a supply of all that was desired, in plants, seed, work-people, and, better still, in accurate data regarding the various processes of the cultivation and manufacture of this article.—*Capper's Three Presidencies, p.* 330.

Assam.—A company for the cultivation of tea, under the title of the Assam Company, was established in March, 1839; and which, with a called-up capital of £193,337, has, as our previous observations have shown, made, up to the present time very profitable progress; having now got its plantations into excellent cultivation, and all its arrangements in admirable working order, it has sold teas to the amount of £90,000, and has a steamboat, a considerable plant and machinery. In the report of the Company, at their annual meeting, held at Calcutta, in Jan., 1850, it was stated, as the result of their operations, that during the year 1849, the manufacturing season was unusually cold and ungenial, in consequence of which the development of leaf for manufacture was much checked. Although some loss was sustained, there was considerable increase in the crop notwithstanding, attributable to the continued improvements in the culture which had been obtained, and improvements over the previous season in some departments of the manufacturing process. The gross quantity of unsorted tea manufactured in the southern division was 207,982 lbs., being 2,973 lbs., less than that of the previous season, but the actual net out-turn was expected to reach 200,000 lbs.

As much as 157,908 lbs. of the crop had been already received and shipped to England. These teas consisted chiefly of the finer qualities. Whilst the crops have been thus sensibly advancing in quantity and quality, and the value of the Company's plantations permanently raised by extended and improved culture, and some increase to the sowings, the total outlay had been somewhat less than the previous year, the expenditure being limited to £500 for a crop of 24,000 acres of tea. With more extended gardens, the produce will be raised at a yet lower rateable cost than at present. The number of acres in cultivation in 1849, was about 12,000: these were not all in bearing, but would shortly be so, and the produce from this extent might be estimated at 300,000 lbs., and the cost of producing this would be about £11,000. 1,010 chests of the produce were sold in London on the 13th of March, 1850, at a gross average of 1s. 11½d. per lb. The produce of 1847, sold in England, was 141,277 lbs., at a gross average of 1s. 8d. per lb.: that of 1848 was 176,149 lbs. which sold at the average of 1s. 8½d. The produce of 1849 was 216,000 lbs., and there was every expectation of the average prices realised being higher than those of the previous years. The season was cold and unfavourable, or the crop would have been 10,000 lbs. more. The exact amounts obtained for the Company's teas in the five years, ending with 1851, will be seen from the following figures:—

	Net produce, lbs.		Average price.	£
1847 ...	144,164	at per lb. ...	1s. 7 1/16d.	11,513
1848 ...	182,953	,, ...	1s. 8¼ d.	15,436
1849 ...	216,000	,, ...	1s. 9½ d.	19,350
1850 ...	253,427	,, ...	1s. 6⅛ d.	18,163
1851 ...	271,427	,, ...	1s. 8½ d.	22,152
1852estmd.	280,000			

This exhibits a progressive increase in the aggregate value of the Company's produce, and this has been effected, it is stated, without any sensible increase of the current expenditure. It exhibits also a rise in the value of the tea (157,942 lbs. having been sold at the high average price of 1s 11½d.), a fact strongly indicative of its increasing excellence. The details of the crop of the season of 1849 showed a net produce of 237,000 lbs. of tea; so that the Company are increasing their cultivation to the extent of nearly ten per cent. per annum, and the increase will doubtless proceed with greater rapidity, whenever the increase of capital enables the directors to extend their operations. The prices in the years 1851, 1852, in London, have been fully maintained at 1s. 3d. to 4s. 4d., according to sorts. Of Assam tea, the sales in the London market in 1851 amounted to 2,200 packages, against 1,900 packages in 1850, and all were freely taken (on account of their great strength) at very full prices.

Kumaon.—Seventy-six packages of Kumaon tea, both black and green, grown by the East India Company, in the Himalayas, as an experiment, were, in 1851, also brought to sale. They were teas of high quality; but being of the light flavored class, and not duly esteemed in the English market, they realised only about their relative value as compared with China teas of similar grade. The Souchong and Pouchong sold at 1s. 1¼d. to 1s. 3½d.; the Hyson, Imperial, and Gunpowder realised 1s 7¾d. to 2s. 6½d. Mr. Robert Fortune, who, in the service of the Horticultural Society of London, gave such satisfaction by his botanical researches in China, was, on his return to England, in 1848, engaged by the Directors of the East India Company to proceed again to the Celestial Empire, and procure and transmit to India such a quantity and variety of the tea plant, that its cultivation in the north-western provinces would be a matter of mere manual labor. Having penetrated about 300 miles into the interior, he left Hong Kong in the middle of 1851 for Calcutta, with a large quantity of choice plants, selected in the green tea districts, and these have flourished as well as could possibly be expected; so that, in the course of a few years, there is every probability that tea will form a considerable article of export from our Indian Presidencies. Mr. Fortune secured the services of, and took with him, eight Chinese, from the district of Weichow, under an agreement for three years, at the rate of fifteen dollars a month each. Six of these were regular tea-manufacturers; the other two were pewterers, whose sole business is that of preparing lead casings for tea-chests.

Punjab.—In the British portion of the Punjaub, it was, at first, resolved to expend £10,000 a year on the cultivation of the tea plant on the banks of the Beas, as well as at Anarkullee, and Kotghur in the Simla jurisdiction. Beyond the Beas there is a series of valleys on to Noonpoor, viz., the Palklun, Kangra, Rillo, &c., from 3,000 to 4,000 feet above the level of the sea, separated from each other by small ranges of hills. The valleys are from three to four miles in breadth, and from sixty to seventy in length: they are sheltered on the north by high mountains.—*Simmonds.*

India Tea Farms, Kumaon Plantations.
Mr. Fortune's Report 1856.

Bhurtpoor.—This place is situated eight or ten miles to the eastward of Nainee Tal, and is at an elevation of about 4,500 feet above the level of the Sea. It consists of a succession of terraces reaching from the bottom to the top of a small Hill; the soil is composed of light loam mixed with small pieces of clay-slate and trap or green stone, of which the adjacent rocks are chiefly composed. In 1851, when I visited this Plantation, it covered about four and a half acres of land. Since that time it has been extended down to the bottom of the Hill, and may now be

about six acres in extent. The bushes are in excellent condition, and fully justify the favourable opinion I formed of the Plantation on my first visit. I then stated, in my Report to Government, that "both the situation and the soil of this Plantation are well adapted to the requirements of the Tea shrub." The centre portion of the land, about half way up to the Hill, is particularly worth pointing out as an example of what I consider most excellent soil for Tea cultivation. A large tract of land in the hills adjoining Bhurtpoor has been set apart for the extension of this farm.

Lutchmesir and Kuppeena.—These Plantations are on a Hill side near Almorah, about 5,000 feet above the level of the Sea, and together cover about seven acres of land. They were very favorably noticed in my former Report. The soil is light and sandy, and wherever it is of sufficient depth it is well adapted for Tea cultivation. The bushes, generally, are in good health, and for many years past have been yielding large crops of Tea. Of the two, Kuppeena is at present in the best condition; many of the plants in Lutchmesir appear to be getting too old and require to be renewed.

Hawulbaugh and Chullar.—These farms are situated about six miles North-West from Almorah, at an elevation of 4,500 feet above the Sea. In 1854, Dr. Jameson states that Hawulbaugh covered fifteen acres, and Chullar thirty. The former has always appeared to me well-adapted for Tea cultivation, both on account of the soil and also from its undulating character. As the best portions, and on which the bushes are in the finest order, I may direct attention to the ground from the large tank up to the Chinese tombs, and particularly to that between the tombs and the Carpenter's shops, and also to those portions South and West of this. The worst land on the farm is that on the West side of the Tea factory. In the Chullar farm adjoining, some portions of the higher land are in very good condition, such, for example, as those below the Tea factory and houses occupied by the Chinese; but the greater part is too wet. The water during the rains seems to ooze out everywhere, and would probably be difficult to drain. Perhaps the best method to adopt in the circumstances would be to plant only on dry land, and on land moderately rich and having a soil of sufficient depth. Land is abundant in all directions about Almorah, which is much better suited for Tea cultivation than most parts of Chullar.

Kutyoor.—A large tract of land has been taken up near the head of the Byznath Valley, about 35 miles Northward from Almorah. This land extends from a stream in the bottom of a Valley up to the top of a Hill on the North side. Its surface is generally undulating in character, and consists of numerous ridges and furrows running from the top of the Hill down to the stream. The soil in this extensive tract of land varies much in its nature and composition. In some places it is a stiff clay, while in others it is loam, darkened and enriched by vegetable matter. A considerable portion of this farm seems well-suited for the cultivation of Tea. Wherever the soil is deep, moderately rich, and *not* marshy, the Tea plants, properly cultivated, will flourish admirably. A Plantation of great extent may be made here, if such portions only are selected and planted. But there are other parts of this farm—and extensive ones—on which it is not adviseable to attempt this cultivation.—*Fortune, 25th October* 1856, *Report in No.* 23. *Selections from the Records of the Government of India.*

Gurhwal Plantations, Guddowli.—This Plantation is in Eastern Gurhwal, near the village of Paorie, in Latitude 30° 8' North, and Longitude 78° 45' East. It consists of a large tract of terraced land extending from a ravine in the bottom of a valley to more than 1,000 feet up the sides of the mountain. The lower portion of this land is said to be about 4,300 feet above the Sea, while the top of the surrounding mountains are from 7,000 to 8,000 feet. In a large Plantation of this kind the soil is, of course, very varied in its composition. In some places it consists of a mixture of loam, sand, and vegetable matter, is deep, and altogether well-suited for Tea cultivation. In other parts it is stony, extremely shallow, and scarcely worth the expense of bringing under cultivation. Much of the higher portion of the farm, planted apparently within the last four or five years, is of this description. In the lower part of the Plantation, on spots where the soil is moderately deep and rich, the plants are succeeding very well and yielding fair crops of Tea. As an example of excellent Tea soil, I may point to a small portion of the Plantation lately planted about half a mile from the work-shops and out-houses on the road to the Overseer's house. Here the plants are growing admirably, and are quite equal to any Plantations of the kind I have met with in China.—*Fortune, 25th October* 1856, *Report in No.* 23, *Selections from the Records of the Government of India.*

Deyrah Dhoon Plantations, Kaolagir.—This farm is situated on the West side of Deyrah, and extends over 400 acres of land. The soil is composed of a mixture of clay, sand, and vegetable matter, varying in depth, but generally deep enough for Tea cultivation. It rests on a gravelly sub-soil, consisting of limestone, sand-stone, clay-slate, and quartz rock, or of such rocks as enter into the composition of the surrounding mountains. In consequence, I believe, of the suggestions contained in former Report, the system of cultivation has entirely changed. The trenches in which the plants were planted were filled up, irrigation was discontinued

nued, and more judgment was exercised in gathering leaves from very young plants. In fact the China system of cultivation was followed as far as it was understood, and the result of all this has been most satisfactory. The remarks I have to make upon the Plantation apply only to the Eastern portions of the farm and to the original nursery at the upper end. I have great pleasure in stating that I have never seen finer or more productive Plantations in China. The plants are in high health, large and bushy, and are yielding annually abundant crops of leaves. Many of the bushes are five and six feet in diameter. One I measured was eight feet, another ten, and both six feet in height. Of course these are the giants of the Plantation. And it is to be noted that these plants are not "drawn up" with few branches and leaves; but they are dense bushes in high health, and formed to give large quantities of Tea.—*Fortune, 25th October* 1856, *Report in No.* 23, *Selections from the Records of the Government of India.*

Punjab Plantations, Nagrowta.—This Plantation is situated in the Kangra Valley, about nine miles from the Old Fort, and covers apparently about four acres of land. It was planted in 1847, and consequently has been in full bearing for several years. In 1855 it produced 1,427lbs. of Tea, or about 330lbs. per acre. The soil is a brownish loam, moderately rich in vegetable matter, and well suited for Tea cultivation. The plants are healthy and vigorous.

Bowarnah.—This is another small experimental Plantation further to the Eastward in the same valley, and about twenty miles from Kangra. It appears to be five or six acres in extent, and was planted about the same time as the former. It is consequently in full bearing, and yields annually upwards of 300lbs. per acre. It is to be remarked, however, that a considerable portion of the produce of both these Plantations is made up from old leaves, which had much better been left on the bushes. The soil of Bowarnah is a brown loam, not quite so rich as that at Nagrouta, but contains a larger portion of sand, and is equally well suited for the cultivation of the Tea shrub. This Plantation is also in a flourishing condition at present.

Holta.—The success which had attended these two small Plantations just noticed, induced the late Governor General, Lord Dalhousie, to comply with the wishes of Dr. Jameson to extend the cultivation of Tea in this part of the country. Accordingly, the lands at Holta were set apart for this purpose. Holta is about 26 miles North East from Kangra, at the foot of the high mountain range, and nearly 4,000 feet above the level of the Sea. Here snow falls annually and covers the ground for several days at one time. The high mountains behind are white with snow for the greater part of the year. The extent of this Plantation is stated to be about 1,200 acres, and of these 700 are already under cultivation. About 20 acres were planted in January 1852, 300 in 1853-54, and 380 in 1855-56. The condition of the plants upon this Plantation is highly satisfactory; they are healthy, vigorous, and quite equal to the best Plantations I have seen in China. Upon the whole, I am inclined to think this Plantation the most promising of all under Dr. Jameson's management, and it certainly reflects great credit both upon him and his Overseer, Mr. W. Rogers.—*Fortune, 25th October* 1856, *Report in No.* 23, *Selections from the Records of the Government of India.*

Future prospects of Tea cultivation in the Himalayas.—From the description which I have given of the Government Plantations it will be observed that the experiments have proved that the Hills in these Provinces are well adapted for the cultivation of Tea. And further, I believe that its cultivation, if carried on in a judicious manner, will prove an excellent investment for foreign capital. But a knowledge of the habits of the plant, and of agriculture or horticulture is, in my opinion, indispensable to make success certain. In every trade and profession of life, a course of teaching is considered indispensable to success. The lawyer, the doctor, the farmer, and the gardener have all to devote long years of careful study to their profession before they will be trusted by the people whom they wish to serve. And I believe it is a rule with the Indigo Planters in Bengal and Tirhoot to make their young men study for some time on their estates before they can be entrusted with the entire management.

On the selection of Land and Cultivation.—It is a fallacy to suppose that Tea can be cultivated profitably on poor land where nothing else will grow. I drew attention to this point in my former Report, and stated that "Tea, in order to be profitable, requires a good sound soil: a light loam, well mixed with sand and vegetable matter, moderately moist, and yet not stagnant or sour," was instanced as most suitable for the requirements of the Tea shrub. There is no scarcity of such lands in the Himalayas, and if such are chosen, success is certain, in so far as the land is concerned. In many instances it would probably be cheaper to buy land from the Zemindars than to clear it. In taking large grants of hill land, the whole will rarely be found suitable for Tea cultivation. In this case those portions only should be cleared and planted where the soil is of such a nature as I have pointed out. *See Remarks on the Bhurtpoor and Kulyoor Lands.*

On plucking the leaves.—This, as I have already pointed out, is a very important part of the business, and requires to be carefully studied. Every vegetable physiologist knows that it is easy to render a plant unhealthy, or to destroy

it altogether by continually depriving it of its leaves. Overseers and Tea Planters ought to study carefully the "Theory of Horticulture," a work of Professor Lindley. In my former Report I directed attention to the bad system of taking too many leaves from very *young plants*, and stated that, for the first two or three years, the leading shoots only should be topped, in order to *form* the plants and make them *bushy*. This has been adopted in the Government Plantations, and the good effects are apparent. But it is also necessary to bring the laws of vegetable physiology to bear upon plants which are fully grown. If too many leaves are annually taken from them, they will soon become sickly, stunted in appearance, and covered with dead branches. And thus the method adopted in order to obtain a large return, although apparently successful for a year or two, will *in the end defeat itself*. In China every child seems to possess intuitively the knowledge necessary to enable it to pluck leaves in the right way, and hence in that country the proper leaves only are taken, and the plants are rarely injured by over-plucking. The object the Chinese have in view is to obtain as large a quantity of leaves as the bushes are capable of yielding, not in any given year, but during the period of their existence; and although not vegetable physiologists, no one knows better than the Chinese that the way to accomplish this is by allowing the bushes to become fully developed, and to keep them in high health and vigour. The natives of India, at present, seem to have no idea of the importance of this principle, and consequently they do much harm to the bushes by over-plucking and by plucking in the wrong way. Instead of nipping off the upper part of the young shoot with its leaves, as the Chinese do, they strip the leaves from it and leave the bare stems. These bare stems generally die down to the nearest leaves, and then the plants get covered with dead stems and present a sickly appearance. Besides the injury this system inflicts on the plants *a great loss is sustained at the same time*. About an inch and a half, and some times more, of the top of the young shoots is soft and succulent, and makes just as good Tea as the leaves themselves. The Chinese know this well, and hence they always nip off this portion with the leaves. The natives of India have no idea of it, and they leave it to die upon the bush. In India large quantities of *old tough leaves* are also stripped from the bushes at each gathering. It is these leaves which form that coarse kind of Tea called "Bohea" at the Government Sales—a Tea totally unsuited for the foreign markets; and even the prices paid for it at the present time in India will not cover the expense of labor and packing. But although these leaves are worthless in Tea-making, they are invaluable to the health of the plants if left upon them, and therefore as few ought to be plucked as is possible. I have no doubt the time will soon come when the principal test of a good Overseer and a flourishing Plantation will be the small quantity of this so-called "Bohea." Since 1848, when I first went to China in the service of Government, large quantities of the best kinds of implements, in use in the Districts already named, have been imported for the use of the manufacturers and for models for imitation in India. Many thousands of Tea plants have also been introduced from these districts, and to these I beg to draw especial notice and to place on record the following remarks. They have been carefully treated and propagated extensively on the various Plantations by Dr. Jameson; but it is to be greatly feared that, in the changes which take place from time to time in Overseers, &c., they will become mixed up and confused with the original plants. I therefore suggest the propriety of taking effectual measures to prevent the possibility of this taking place, whatever changes may occur amongst Overseers or other workmen. It is just possible that the faults found by the London Brokers with Himalayan Teas may be remedied by the new and superior method of manipulation; but if the cause of this lies in the constitution of the original variety of the plant, then those obtained in the best Districts of China will prove of very great value. All the plants from the black Tea Districts ought therefore, to be kept together, and marked so that no mistake can by any possibility occur, and the same thing ought to be done with the plants from the green Tea Districts, marking particularly those from Hwuy-chow. The different Districts were carefully marked in the lists sent from China by me with the plants and seeds. When I visited these Provinces in 1851, I had some hopes that the Zemindars would speedily take to the cultivation of Tea on their farms, and that the Hill sides would soon be dotted over with small Plantations, such as one meets with in the Tea Districts of China. These hopes, I regret to say, have not yet been realized. There seems to be a deeply-rooted prejudice against the innovation which it may still take some years to overcome. One man, in particular, has acted in such an extraordinary and unaccountable manner that I cannot help noticing the circumstances in this Report. The circumstances in which this man was placed were altogether most favourable. Supposing the [illegible] to have been yielding annually 800lbs. of [illegible] leaves per acre, which is a very low average, he would have been realizing Rupees 80 an acre for his land, or Rupees 640 for the 8 acres under Tea—a sum I should imagine twice as large as he would make from any other crop and with less trouble. Captain Ramsay has another Plantation on the old Sepoy Lines near Hawulbaugh. This is at present in most excellent condition and is most promising. If managed in a proper manner, it will be very

valuable in a year or two. All that it requires at present is—*first*, to be kept clean; *secondly*, the plants *formed* by topping the leading shoots in order to make them *bushy*; and, *thirdly*, good drains made and kept open to carry off the springs, which in some places ooze from the Hill side. In two years more it will yield a large crop of leaves, and will go on yielding for many years. Although Tea cultivation amongst the Zemindars has not made much progress up to the present time, yet it is by no means to be regarded as hopeless. In all countries, it is difficult to induce the inhabitants to make any change in articles of cultivation, and the more ignorant they are, the more averse are they to any innovation. Even in England, in which there is perhaps less of this feeling now than in most other countries, every one can call to mind instances in which great improvements in agriculture were long retarded, owing to the ignorance and prejudice of the people. But although the introduction of Tea cultivation amongst the Zemindars may be slow at first, yet, in the end, it is almost certain to be adopted. And when once the prejudices which now exist against it have passed away, when a few have felt the advantage which such a crop is certain to confer upon them, others will speedily follow in their footsteps, and as in China, every village amongst these Hills will furnish its portion of Tea, the coarse kinds of which the natives will consume themselves, and the rest will be sold to merchants for consumption in the plains, or for exportation. The large amount of foreign capital, which will necessarily be brought into these Provinces to carry on Tea cultivation on an extensive scale, will be of very great importance to the people, and this alone is well worth the attention which Government has bestowed upon it. But although the resources of the country will thus be largely developed, and a good demand for labour established, these benefits will be slight when compared with those which would be conferred upon the inhabitants, could they be induced to cultivate and produce the article themselves. They would not only have, for their use, a simple and healthy beverage to drink, but it would also furnish them with the means of procuring a few of those harmless luxuries, which would have a tendency to raise their character, and to make them, as a people, more intelligent and industrious. At present, as a general rule, the natives of these Hills are lazy and indolent, and seem perfectly satisfied with a bare subsistence—indeed they can scarcely be said to enjoy the common necessaries of life. Their clothing is miserable in the extreme, and their dwellings would scarcely be considered fit for the lower kinds of animals, I will not say in England, but even in a half civilized country like China. If a change in the habits of the people could be brought about by the cultivation of Tea, such a famine as that which was felt in Kumaon and Gurhwal this year is not likely to occur. But if a people are so indolent as to allow their lands to lie waste, or only half tilled—if they are content with their daily bread and make no provision for the future—a dry season such as the last may occur at any time when the crops fail and a famine is the result. Such a state of things could never take place in China, at least from such slight causes, because the Chinese feel that the necessaries and luxuries of life are indispensible to their happiness, and they are industrious in order to supply them. Another great advantage of Tea cultivation for the Hill farmers is this; it would never fail to yield a crop, even in the driest seasons. Last spring I had an opportunity of seeing all the Government Plantations in the dry weather, and, when nearly every other crop had failed, the Tea seemed uninjured. This is a fact of very great importance, and shows that, with proper management, there is scarcely a chance of failure even in the driest year. The poor in India are never likely to enjoy this healthy and refreshing beverage, until they can produce it themselves on their own lands, for the price will be higher than they can afford to pay. It is for these reasons I estimate so highly the importance of Tea cultivation amongst the Zemindars in the Himalayas. I am quite sure that, notwithstanding the prejudices which exist in their minds against it at present, if the influential Officers of Government as a body were to encourage its cultivation, these prejudices would rapidly disappear. And when they have passed away,—when small Tea Plantations are seen dotted on every Hill side as in China—when the natives are met on the roads in large numbers carrying the produce of their little farms to the market towns, or to the factories of foreigners for sale,—a boon will have been conferred upon them of inestimable nature.—*Fortune, 25th October* 1856, *Report in No.* 23, *Selections from the Records of the Government of India.*

Tea plants: *Are the Black and Green Teas from the same plant*?—The plant in cultivation about Canton, from which the Canton teas are made, is known to botanists as the *Thea bohea*, while the more northern variety, found in the green tea country, has been called *Thea viridis*. The first appears to have been so named upon the supposition that all the black teas of the Bohea mountains were obtained from this species, and the second was called *viridis* because it furnished the green teas of commerce. These names seem to have misled the public, and hence many persons, until a few years back, firmly believed that black tea could be made only from *Thea bohea*, and green tea only from *Thea viridis*. In my "Wanderings in China,' published in 1846, I made some observation upon the plants, from which tea is made in different parts of China, while I acknow-

ledged that the Canton plant, known to botanists as *Thea bohea*, appeared distinct from the more northern one called *Thea viridis*, I endeavoured to show that both black and green teas could be made from either, and that the difference in the appearance of these teas, in so far as colour was concerned, depended upon manipulation, and upon that only. In proof of this I remarked that the black tea plant found by me near Foo-chow-foo, at no great distance from the Bohea hills, appeared identical with the green tea plant of Che-kiang.

It is now well known that the fine Moning districts near the Poyang Lake, which are daily rising in importance on account of the superior character of their *black* teas, formerly produced nothing else but *green* teas. At Canton green and black teas are made from the *Thea bohea* at the pleasure of the manufacturer, and according to demand.

Green tea.—When the leaves are brought in from the plantations they are spread out thinly on flat bamboo trays, in order to dry off any superfluous moisture. They remain for a very short time exposed in this manner, generally from one to two hours; this however depends much upon the state of the weather. In the mean time the roasting-pans have been heated with a brisk wood fire. A portion of leaves are now thrown into each pan and rapidly moved about and shaken up with both hands. They are immediately affected by the heat, begin to make a crackling noise, and become quite moist and flaccid, while at the same time they give out a considerable portion of vapour. They remain in this state for four or five minutes, and are then drawn quickly out and placed upon the rolling table. The rolling process now commences. Several men take their stations at the rolling table and divide the leaves amongst them. Each takes as many as he can press with his hands, and makes them up in the form of a ball. This is rolled upon the rattan worked table, and greatly compressed, the object being to get rid of a portion of the sap and moisture, and at the same time to twist the leaves. These balls of leaves are frequently shaken out and passed from hand to hand until they reached the head workman, who examines them carefully to see if they have taken the requisite twist. When he is satisfied of this the leaves are removed from the rolling table and shaken out upon flat trays, until the remaining portions have undergone the same process. In no case are they allowed to lie long in this state, and sometimes they are taken at once to the roasting-pan. Having been thrown again into the pan, a slow and steady charcoal fire is kept up, and the leaves are kept in rapid motion by the hands of the workmen. Sometimes they are thrown upon the rattan table and rolled a second time. In about an hour or an hour and a half the leaves are well dried and their colour has become *fixed*, that is, there is no longer any danger of their becoming black. They are of a dullish green colour, but become brighter afterwards. I am not now alluding to teas which are coloured artificially. The most particular part of the operation has now been finished, and the tea may be put aside until a larger quantity has been made. The second part of the process consists in winnowing and passing the tea through sieves of different sizes, in order to get rid of the dust and other impurities, and to divide the tea into the different kinds known as twankay, hyson skin, hyson, young hyson, gunpowder &c. During this process it is refired, the coarse kinds once, and the finer sorts three or four times. By this time the colour has come out more fully, and the leaves of the finer kinds are of a dull bluish green. It will be observed, then, with reference to green tea—1st, that the leaves are roasted almost immediately after they are gathered; and 2nd, that they are dried off quickly after the rolling process.—*Fortune's Tea Districts, pages* 272, 277, *and* 278.

Black tea.—When the leaves are brought in from the plantations they are spread out upon large bamboo mats or trays, *and are allowed to lie in this state for a considerable time.* If they are brought in at night they lie until next morning. The leaves are next gathered up by the workmen with both hands, thrown into the air and allowed to separate and fall down again. They are tossed about in this manner, and slightly beat or patted with the hands, for a considerable space of time. At length, when they become soft and flaccid, they are thrown in heaps and allowed to lie in this state for about an hour or perhaps a little longer. When examined at the end of this time, they appear to have undergone a slight change in colour, are soft and moist, and emit a fragrant smell.—*Fortune, Tea Districts, page* 278. The next part of the process is exactly the same as in the manipulation of green tea. The leaves are thrown into an iron pan, where they are roasted for about five minutes and then rolled upon the rattan table. After being rolled, the leaves are shaken out, thinly, on sieves, and exposed to the air out of doors. A framework for this purpose, made of bamboo, is generally seen in front of all the cottages amongst the tea-hills. The leaves are allowed to remain in this condition for about three hours: during this time the workmen are employed in going over the sieves in rotation, turning the leaves and separating them from each other. A fine dry day, when the sun is not too bright, seems to be preferred for this part of the operation. The leaves, having now lost a large portion of their moisture, and having become reduced considerably in size, are removed into

the factory. They are put a second time into the roasting pan for three or four minutes, and taken out and rolled as before.—*Fortune, page* 279. The charcoal fires are now got ready. A tubular basket, narrow at the middle and wide at both ends, is placed over the fire. A sieve is dropped into this tube and covered with leaves, which are shaken on it to about an inch in thickness. After five or six minutes, during which time they are carefully watched, they are removed from the fire and rolled a third time. As the balls of leaves come from the hand of the roller they are placed in a heap until the whole have been rolled. They are again shaken on the sieves as before and set over the fire for a little while longer. Sometimes the last operation, namely, heating and rolling, is repeated a fourth time : the leaves have now assumed their dark colour. When the whole has been gone over in this manner, it is then placed thickly in the baskets, which are again set over the charcoal fire. The workman now makes a hole with his hand through the centre of the leaves, in order to allow vent to any smoke or vapour which may rise from the charcoal, as well as to let the heat up, and then covers the whole over with a flat basket. Previous to this the heat has been greatly reduced by the fires being covered up. The tea now remains over the slow charcoal fire until it is perfectly dry ; it is, however, carefully watched by the manufacturer, who every now and then stirs it up with his hands, so that the whole may be equally heated. The black colour is now fairly brought out, but afterwards improves in appearance : the after processes, such as sifting, picking, and refiring, are carried on at the convenience of the workmen. If the reader is desirous of obtaining more information upon this subject, he should consult Mr. Balls' ' Cultivation and Manufacture of Tea.' It will be remarked, therefore, with reference to the leaves which are to be converted into black tea,—1st, that they are allowed to lie for some time spread out in the factory after being gathered and before they are roasted ; 2d, that they are tossed about until they become soft and flaccid, and then left in heaps, and that this also is done before they are roasted ; 3d, that after being roasted for a few minutes and rolled, they are exposed for some hours to the air in a soft and moist state ; and 4th, that they are at last dried slowly over charcoal fires. The differences in the manufacture of black and green teas are therefore most marked, and I think fully account for the difference in colour, as well as for the effect produced on some constitutions by green tea, such as nervous irritability, sleeplessness, &c. This is shown in some observations made by Mr. Warrington, of Apothecaries Hall, in his paper which I have already quoted.—*Fortune, Tea Districts, page* 281.

Raw tea leaves.—That is, just as they had been plucked from the bushes, and unmanufactured, were also found by Fortune exposed for sale in the market. They were sold at from three farthings to five farthings a pound ; and as it takes about four pounds of raw leaves to make one pound of tea, it follows that the price paid, was at the rate of threepence to fivepence a pound, but to this must be added the expence of manipulation. In this manner the inhabitants of large towns in China, who have no tea-farms of their own, can buy the raw leaves in the market and manufacture the beverage for themselves and in their own way.—*A Res. among the Chi. p.* 45.

Tea, Caper.—On entering one of the hongs or factories, says Fortune, the first thing to which we directed our attention was the tea which was to be made into "caper." I have already stated, he continues, that this description of tea is produced near a place called Tai-shan, in the Canton province, a few miles inland from the city. Here, it undergoes only the first process of manipulation ; that is, it is fired, rolled, and dried, and the colour fixed but nothing further is done to it. It is then packed up in mat-bags or baskets and sent down to Canton to be made up in the approved manner, and scented for exportation. On examining this tea, it has a very rough appearance, and in the state in which it was, seemed unsuited for the foreign markets. The workmen were busily engaged in remaking it during the time of our visit, and they went to work in the following manner : A convenient quantity, about twenty or thirty pounds, was thrown into the drying-pan, which had been heated for the operation. Here it was sprinkled with a basinful of water, and rapidly turned over with the hands of the workman. The dry leaves immediately imbibed the moisture and became soft and pliable. This softening process prevented them from breaking down into dust, and fitted them also to take any form which was considered desirable by the manipulator. The water used on this occasion stood in a large basin adjoining the drying-pans and had a yellow dirty appearance which Fortune was rather at a loss to account for. At first sight I thought it was mixed with some ingredient which was intended to give a peculiar tint or colour to the tea, but on inquiry it turned out that my conjecture was wrong. Our guide, on being appealed to for information on the subject, coolly informed us that " there was nothing in the water, it was quite clean, but that the workmen were in the habit of washing their hands in it !" As soon as the leaves had become softened by the moisture and heat in the pan, they were taken out and put into a strong canvas bag, and twisted firmly into a round form, resembling a football. This bag was then thrown down on the floor, which had been covered with a mat, and a man jumped upon it

with both feet, supporting himself at the same time by laying hold of a bamboo pole, which had been erected in a horizontal position for the purpose. The heel, sole, and toes of his feet were now kept in perpetual motion, in turning and twisting the ball while the weight of his body compressed it gradually into a smaller size. As the bulk of the ball is thus reduced by pressure, the canvass slackens, and it is necessary for the workman from time to time to jump off it and tighten its mouth by giving it an extra twist with his hands. The balls by this process of rolling and twisting, become at last very hard and solid, and are then thrown on one side, and allowed to be in this state for several hours: if this work has been done in the evening, they remain all night. By this system of pressing, twisting, and rolling, the greater portion of the moist leaves take a circular form, which goes on to perfection during the subsequent drying which the leaves have, of course, to undergo, and ends in the production of the round shot-like appearance by which this kind of tea is known. It is a most curious sight to a stranger who sees the mode of making this tea for the first time. A whole row of these men, nearly naked when the weather is warm, each with a large ball under his feet, which he is twisting and rolling with all his might, is so unexpected a sight in tea-making. The clever sketch in his Frontispiece by his friend Mr. Scarth gives a good idea of this curious process. The best kind of caper takes the round form naturally during the manufacture of souchong or congou, but as I have already mentioned only a very small quantity, about five per cent. could be procured in this way. By far the greatest portion of the caper exported is manufactured in the manner I have just described. But as I am letting out all the secrets of tea manufacture I may just as well notice another mode of making caper which is scarcely as legitimate as the former. In one corner of the factory we observed a quantity of tea exceedingly coarse in quality, in fact the refuse of that which we had been examining. All the art of the manipulator, in so far as heating and pressing and rolling in the usual way, was not equal to make a good-looking "caper" out of this. The leaves were too old, too large and coarse in their present state. But although there might be some difficulty even to a Chinese in making small leaves into large ones, there was none whatever in making large leaves small and their mode of doing this was as follows. These coarse leaves were first of all heated and moistened as the others had been, in order to make them soft and pliable. They were then thrown into square boxes and chopped up for some time until the size of the leaves was reduced. When this was accomplished to the satisfaction of the operator they were then made into nice-looking round "caper" suitable for the market. The origin of the name this tea bears is no doubt from its resemblance in form to the flower buds of the caper-bush of the south of Europe, and yet it is rather a curious coincidence that the greater part of caper tea finds its market in the Cape of Good Hope. Our Chinese guide informed us, with a peculiar grin on his countenance, that when there is a large demand for green teas, caper is converted into imperial and gunpowder by dyeing it with prussian blue and gypsum. The "*orange pekoe*" of commerce which is produced in the same district as the caper, is somewhat like congou in make but the leaf is much more wiry and twisted, and is of a lighter complexion. The infusion produced by this tea has a yellow or orange tint, and hence the name of orange pekoe which it bears. Like hyson pekoe amongst green teas, this is made from the young leaves soon after they unfold themselves in spring, and hence many of the leaves are covered with white hairs which are formed at this season of the year. These hairy leaves are called pekoe ends by the trade. A large quantity of this tea is gathered and dried by itself, while another portion is taken out of that of which the "caper" is ultimately made."—*A Res. among the Chi. page* 212.

Black Tea.—During the days of the East India Company's Charter all the best black teas were produced in the province of Fokien. The towns of Tsin-tsun and Tsong-gan in the vicinity of the far-famed Woo-e hills were then the chief marts for the best black teas exported by the Company. At that period the districts about Ning-chow, in the Kiangse province, were known only for their green teas. Now however, and for many years past, although the Fokien black teas are, and have been, largely exported, those produced in the Ning-chou districts have risen in the public estimation, and I believe, generally fetch very high prices in the English market. If there be any one now who still clings to the old idea that green teas can be made only from the plant called *Thea viridis*, and black ones only from *Thea bohea*, he will find a difficulty in giving credit to the account I have to give of the manner in which the Ning-chou districts have changed their green teas into black. But, however difficult it may be to get rid of early prejudices, facts are stubborn things and the truth of what I have to state may be fully relied upon. Many years ago a spirited Chinese merchant who, no doubt saw well enough, that black and green teas could be made easily enough from the same plant, had a crop of black teas made in the Ning-chow district and brought to Canton for sale. This tea was highly approved of by the foreign merchants at that port, and was bought, I believe, by the great house of Messrs. Dent and Company and sent to England. When it got home it found a ready sale in the market and at once established itself as a black tea of the

first class. Year by year after this the demand for this tea steadily increased and was as regularly supplied by the Chinese. At the present time the Ning-chow districts produced black teas only, while in former days they produced only green. If proof were wanting, this would appear sufficient to show that black or green teas can be made from any variety of the tea plant, and that the change of colour in the manufactured article depends entirely upon the mode of manipulation.—*A Res. among the Chinese, page* 393.

Brick tea of Thibet.—A sample of this curious product was shown by the East India Company in 1851. It is formed of the refuse tea-leaves and sweepings of the granaries, damped and pressed into a mould, generally with a little bullock's blood. The finer sorts are friable masses, and are packed in papers; the coarser sewn up in sheep's skin. In this form it is an article of commerce throughout Central and Northern Asia and the Himalayan provinces; and is consumed by Mongols, Tartars, and Tibetans, churned with milk, salt, butter, and boiling water, more as a soup than as tea proper. Certain quantities are forced upon the acceptance of the Western tributaries of the Chinese Empire in payment for the support of troops, &c.; and is hence, from its convenient size and form, brought into circulation as a coin, over an area greater than that of Europe.—*Dr. Hooker, in Jury Reports.* (*Simmonds*).

Tea, the varieties manufactured.—In order to give the reader some idea of the different sorts of teas manufactured for the European and American markets, I cannot do better than quote some excellent remarks on this subject by Sir John Francis Davis, in his work, "The Chinese." "As tea has always held so principal a place in our intercourse with China, it requires some particular consideration as an article of commerce. We have seen before, that the fineness and dearness of tea are determined by the tenderness and smallness of the leaf when picked. The various descriptions of the Black diminish in quality and value as they are gathered later in the season, until they reach the lowest kind, called by us Bohea, and by the Chinese (Ta-cha), 'large tea' on account of the maturity and size of the leaves. The early leaf buds in Spring, being covered with a white silky down, are gathered to make Pekoe, which is a corruption of the Canton name Pak-ho 'white down.' A few days' longer growth produce what is here styled 'black leaved pekoe.' The more fleshy and matured leaves constitute Souchong; as they grow larger and coarser they form Congou; and the last and latest picking is Bohea. Tea-farmers, who are small proprietors or cultivators, give the tea a rough preparation, and then take it to the contractors, whose business it is to adapt its farther preparation to the existing nature of the demand. The different kinds of tea may be considered in the ascending scale of their value.

1. Bohea, which in England is the name of a quality, has been already stated to be, in China, the name of a district where various kinds of black tea are produced. The coarse leaf brought under that name to Great Britain is distinguished by containing a larger proportion of the woody fibre than other teas; its infusion is of a darker colour, and as it has been more subjected to the action of fire, it keeps a longer time without becoming musty than the finer sorts. Two kinds of Bohea are brought from China: the lowest of these is manufactured on the spot, and therefore called "Canton Bohea," being a mixture of refuse Congou with a coarse tea called Woping, the growth of the province. The better kind of Bohea comes from the District of that name in Fokein, and, having been of late esteemed equally with the lower Congou teas, has been packed in the same square chest, while the old Bohea package is of an oblong shape.

2. Congou, the next higher kind, is named from a corruption of the Chinese Koong foo, 'labour or assiduity.' It formed for many years the bulk of the East India Company's cargoes; but the quality gradually fell off, in consequence of the partial abandonment of the old system of annual contracts, by which the Chinese Merchants were assured of a remunerating price for the better sorts. The consumption of Bohea in Great Britain, has of late years increased, to the diminition of Congou, and the standard of the latter has been considerably lowered. A particular variety, called campoi, is so called from a corruption of the general name Kiew-peoy, 'Selection—choice'; but it has ceased to be prized in Great Britain, from the absence of strength, a characteristic which is stated to be generally esteemed beyond delicacy of flavour.

3. Souchong (Scaou-choong, 'small, or scarce sort') is the finest of the stronger black teas, with a leaf that is generally entire and curly, but more young than in coarser kinds. What is called 'Padre Souchong' is packed in separate paper bundles, of about half a pound each, and is so fine as to be used almost exclusively for presents. The probability is that its use in that way by the Catholic missionaries first gave rise to to the name. The finest kinds of Souchong are sometimes scented with the flowers of the Chloranthus inconspicuus, and Gardenia florida; and they cannot be obtained, even among the Chinese except at high prices. A highly crisped and curled leaf called Sonchi, has lately grown into disrepute and been much disused, in consequence of being often found to contain a ferruginous dust, which was probably not intended as a fraud, but arose from the nature of the ground, where the tea had been carelessly and dirtily packed.

4. Pekoe being composed mainly of the young spring-buds, the gathering of these must, of course, be injurious in some degree to the future produce of the shrub, and this description of tea is accordingly both dear and small in quantity. With a view to preserving fineness of flavour, the application of heat is very limited in drying the leaves, and hence it is, that Pekoe is more liable to injury from keeping than any other sort of tea. There is a species of Pekoe made in the Green tea country from the young buds in like manner with the black kind; but it is so little fired that the least damp spoils it; and for this reason, as well as on account of its scarcity and high price, the Hyson-pekoe, as some call it, has never been brought to England. The mandarins send it in very small canisters to each other, or to their friends, as presents, under the name of Loong-tsing, which is probably the name of the district where the tea is made. Green teas may generally be divided into five denominations, which are 1. Twankay; 2. Hyson-skin; 3. Hyson; 4. Gunpowder; 5. young Hyson. Twankay tea has always formed the bulk of the green teas imported into England being used by the retailers to mix with the finer kinds. The leaf is older and not so much twisted and rolled as in the dearer descriptions: there is altogether less care and trouble bestowed on its preparation. It is, in fact, the Bohea of green teas; and the quantity of it brought to England has fully equalled three fourths of the whole importation of green. Hyson skin is so named from the original Chinese term, in which connection the skin means the refuse or inferior portion of anything; in allusion, perhaps, to the hide of an animal or the rind of fruit. In preparing the fine tea called Hyson all those leaves that are of a coarser yellow and less twisted or rolled appearance are set a part and sold as the refuse or skin tea at a much inferior price. The whole quantity, therefore, depends on, and bears a proportion to, the whole quantity of Hyson manufactured, but seldom exceeds two or three thousand chests in all. The word Hyson is corrupted from theChinese name which signifies flourishing spring, this fine sort of tea being of course gathered in the early part of the season.—*Fortune's Wandering, pages* 319, 220, 221 and 222.

Mr. Williams writing on the same subject says. Its botanical affinities ally it to the Camellia, and both have the same name among the Chinese; botanists call it Thea. and it is still a matter of dispute whether the different sorts are distinct species or mere varieties. Mr. Fortune found them growing together, and Loureiro, a medical missionary in China, regards all the varieties as ascribable, to these causes, though De Candolle divides them into three species, *Thea bohea*, *Thea viridis*, and *Thea cochinsinensis*. The plant is from three to ix feet high, and usually presents a dense mass of foliage on an infinite number of small twigs, a result of the practice of cutting it down. In Assam where it has been found wild, it reaches the height of thirty feet. The leaf is a dark green color, of an oblong oval shape, and the flowers are white, inodorous, and single; the seeds are like hazel-nuts in size and colour, three of them being inclosed in a hard husk, and so oily as to corrupt soon after ripening; this oil is rather acrid and bitter, but is useful for various purposes.—*Williams, Vol.* I, *page* 127.

The Chinese names given to the various sorts of tea the produce of these varieties, are derived for the most part from their appearance or place of growth; the names of many of the best kinds are not commonly known abroad. *Bohea* is the name of the Wu-i hills (or Bu-i as the people on the spot call them), where the tea is grown, and not a term for a particular sort among the Chinese, though it is applied to a very poor kind of black tea at Canton; *Sunglo* is likewise a general term for the green teas produced on the hills in Kiangsu. The names of the principal varieties of black tea are as follows: *Pecco*, "white hairs," so called from the whitish down on the young leaves, is one of the choicest kinds and has a peculiar taste; *Orange Pecco*, called *shang hiang*, or "most fragrant," differs from it slightly; *Hungmuey*, "red plum blossoms," has a slightly reddish tinge; the terms *prince's eyebrows, carnation hair, lotus kernel, sparrow's tongue, fir-leaf pattern, dragon's pellet*, and *dragon's whiskers*, are all translations of the native names of different kinds of Souchong or Pecco. Souchong, or *sian chung*, means *little plant* or sort, as *Pouchong*, or *folded sort*, refers to the mode of packing it; Campoi is corrupted from *kan pei*, *i. e.* carefully fired; *Chulan* is the tea scented with the chulan flower, and applied to some kinds of scented green tea. The names of green teas are less numerous: *Gunpowder*, or *ma chu*, [illegible] hemp pearl, derives its name from the form into which the leaves are rolled; *ta chu*, or "great pearl," and *chu lan*, or "pearl flower," denote two kinds of *Imperial; Hyson*, or *yu tsien*, *i. e.* before the rains, originally denoted the tenderest leaves of the plant, and is now applied to the *young Hyson;* as also another name, *mei pien*, or "plum petals;" while *hi chun*, "flourishing spring," describes *Hyson; Twankay* is the name of a stream in Chehkiang, where this sort is produced; and *Hyson skin* or *pi cha*, i. e. skin tea, is the poorest kind, the siftings of the other varieties; *Oolung*, "black dragon," is a kind of black tea with green flavor. Ankoi teas are produced in the district of Nganki, not far from Tsinenchan fu, possessing a peculiar taste, supposed to be owing to the ferruginous nature of the soil. De Guignes speaks of the Pu-'rh tea, from the place in Kiangsu where it grows, and

says it is cured from wild plants found there, the infusion is unpleasant, and used for medical purposes. The Mongols and others in the west of China prepare tea by pressing it when fresh into cakes like bricks, and thoroughly drying it in that shape to carry in their wanderings.—*Williams' Middle Kingdom, Vol.* II, *page* 135. The poorer natives substitute the leaves of a species of Rhamnus or Fallopia, which they dry; Camellia leaves are perhaps mixed with it, but probably to no great extent. The refuse of packing houses is sold to the poor at a low rate.—*Williams' Middle Kingdom, Vol.* II, *page* 136.

Manufacture.—The questions have been often discussed whether black or green teas are made from the same plant, and whether they can be made from each other. Chinese account ascribes the difference in the color of black and green tea wholly to the mode of preparation; green tea is cured more rapidly over the fire than the black, and not dried in baskets afterwards; but throwing the leaf into red hot pans, and subsequently exposing it to the sun and drying it over a covered fire makes it black. Green tea can therefore be changed into black, but the contrary cannot be done, because the leaf is already black. Green tea is made by simply drying the leaves, "young ones over a gentle heat and old ones over a hot fire, for about half an hour, or while two incense-sticks can burn out." By this mode more of the essential oil remains in the leaf, and is one reason, perhaps, why a greater proportion of green tea spoils or becomes musty during the long land journey to Canton. The tea cured for home consumption is not as carefully or thoroughly fired as that intended for exportation, and consequently probably retains more of its peculiar properties.—*Williams' Middle Kingdom, Vol.* II, *page* 133.

Testing of Tea.—Both kinds are repeatedly tested during the various stages of manufacture by pouring boiling water on a few leaves, to observe the color, aroma, taste, strength, and other properties of the infusion. As many as fifteen drawings can be made from the best leaves before the infusion runs off limpid. In the usual manner of Chinese writings ten things are specifically mentioned by the native author to be observed in selecting green tea; such as, that the leaf must be green, firmly rolled, and fleshy; there must be no petioles adhering, no dirty or broken leaves of twigs; and the infusion should be greenish, aromatic, and oily. In selecting all kinds of tea, the color, clearness, taste, and strength of the infusion are the principal criteria; the weight of the parcels, taste and color of the dry leaf, and its smell when strongly breathed upon, are also noticed. Some Aukoi teas are tried by a lodestone to detect the presence of minute particles of iron.—*Williams' Middle Kingdom.*

Soil suitable for its Cultivation.—The soil most favourable for the growth of tea is a rich sandy earth, with a large proportion of vegetable mould in it, and situations on the sides of hills, where there is a good exposure and supply of water, produce the best flavoured leaves. The patches above the rice grounds are favorite situations, but the plant is seldom cultivated on the plains or lowlands. A loamy subsoil, with a sandy loose covering, produces a good crop of leaves and in the plantations visited in the Aukoi hills in Fuhkien, much of it is colored with iron. The greater part of the tea exported is grown in the provinces of Fuhkein, Chehkiang, and Kiangsu, but all the eighteen produce it, except in the northern regions lying along the base of the table-land in Chihli and Shansi, though the eastern parts, between the parallels of 25° and 35° north, afford it in the greatest perfection and abundance. With the increased demand its cultivation has extended, and perhaps that of cotton has diminished in a corresponding degree, the southern hills of Fuhkein, the western parts of Kwangtung, and districts in Kwangsi, also afford it for foreign markets. Russia is supplied from Szchuen and the adjoining region, while Birmah gets a part from Yunnan.—*Williams' Middle Kingdom, Vol.* 1, *page* 127.

Cultivation.—Tea is usually raised by individuals, who cultivate a few dozen or scores of shrubs upon their own lands, and either cure the leaves themselves, or sell them to their neighbours, after assorting them according to their quality. There are very few large plantations under the care of rich landlords, but each little farmer raises tea as he does cotton, silk, or rice upon his own premises. The seeds are thickly planted in nursery beds, because many of them fail from their oily nature, and when the nurslings are a foot or more high they are transplanted into rows about four feet apart; sometimes they are put in the spot designed for them, and if more than one seed in a hole succeeds, it is removed. No preparation of the ground is necessary, nor is much care taken to keep the shrubs in a healthy state; those near Canton are usually covered with lichens, and when thus neglected worms attack the wood. The leaves are picked from the plant when three years old, but it does not attain full size before six or seven, and thrives according to circumstances and care from fifteen to twenty years, being in fact gradually killed by constantly depriving it of its foliage. Pruning the twig to increase the quantity of leaves develops the branches laterally, so that large, healthy shrubs resemble a collection of plants rather than a single bush. The interspaces are frequently sown with vegetables, and the practice is to spread them as much as possible in order to prevent their being shaded. In the Bohea hills, where the best tea is produced, there is, accord-

ing to the Chinese, considerable difference in the quality of the leaves from gardens not very far apart, and connoisseurs are as particular to inquire the name of the place whence their tea comes as western wine drinkers are to learn the names of the vineyards producing the best brands. The produce of old and celebrated nurseries is carefully collected and cured by itself, and one native authority states that the prices of these particular lots vary from $15 to $100 per pound.—*Williams' Middle Kingdom, Vol.* II, *page* 128. The annual produce of a single plant of large size is said to be from 16 or 18 to 24 ounces; but an English visitor to the Ankoi hills ascertained that the common average yield was not far from six ounces, and that a thousand square yards contained between 300 and 400 plants. Three crops of leaves are gathered during the season. The first picking is about the middle of April, or whenever the tender leaf buds begin to open, and while the leaves are still covered with a whitish down; these, though not very numerous, produce the finest tea, and the notion that some of the delicate sorts of tea are made from the flowers has originated from the whitish appearance this down imparts to them; for no tea can be made from the thin, scentless petals of the tea blossom. The second gathering is about the first of May, when the shrubs are covered with full-sized leaves. Chinese writers say that the weather has great influence upon the condition of the leaves, and that an excess or want of rain mildews or withers them, so as materially to affect the quality and quantity of the crop. When the proper time has arrived, a large number of hands should be employed to gather the leaves rapidly, and at this period the whole population, men, women, and children, find employment. Each person can on an average pick 13lbs. of leaves in a day, for which the wages are about six cents. The third crop is collected about the middle of July, and there is also a fourth gleaning in August, called *tsiulu*, i. e. autumn dew, from the name of the season in which it takes place; the three previous ones called first, second, and third springs. The two last crops afford only inferior kinds, seldom exported.

Cultivation in China.—The tea-shrub is cultivated every where and often in the most inaccessible situations; such as on the summits and ledges of precipitous rocks. Mr. Ball states that chains are said to be used in collecting the leaves of the shrubs growing in such places; and the greatest quantity is grown on level spots on the hill-sides, which have become enriched, to a certain extent, by the vegetable matter and other deposits which have been washed down by the rains from a higher elevation. Very little tea appeared to be cultivated on the more barren spots amongst the hills.—*Fortune, Tea Districts, page* 237.

Soil.—The soil of the tea-lands about Woomshan seemed to vary considerably. The most common kind was a brownish-yellow adhesive clay. This clay, when minutely examined, is found to contain a considerable portion of vegetable matter mixed with particles of the rocks above enumerated. In the gardens on the plains at the foot of the hills the soil is of a darker colour, and contains a greater portion of vegetable matter, but generally it is either brownish yellow, or reddish yellow. As a general rule the Chinese always prefer land which is moderately rich, provided other circumstances are favourable. By far the greatest portion of the tea in this part of the country is cultivated on the sloping sides of the hills. I observed a considerable quantity also in gardens on the level land in a more luxuriant state even than that on the hill-sides; but these gardens were always a considerable height above the level of the river, and were consequently well drained.—*Fortune, Tea Districts, page* 255.

Cultivation and management of plantations.—In the black-tea districts as in the green, large quantities of young plants are yearly raised from seeds. These seeds are gathered in the month of October, and kept mixed up with sand and earth during the winter months. In this manner they are kept fresh until spring, when they are sown thickly in some corner of the farm, from which they are afterwards transplanted. When about a year old they are from nine inches to a foot in height, and ready for transplanting. They are planted in rows about four feet apart. Five or six plants are put together in each hole, and these little patches are generally about three or four feet from each other in the rows. Sometimes, however, when the soil is poor, as in many parts of Woo-e-shan, they are planted very close in the rows, and have a hedge-like appearance when they are full grown.—*Fortune's Tea Districts, page* 258. The young plantations are always made in spring, and are well watered by the rains which fall at the change of the monsoon in April and May. The damp, moist weather at this season enables the young plants to establish themselves in their new quarters, where they require little labour afterwards, except in keeping the ground free from weeds A plantation of tea, when seen at a distance, looks like a little shrubbery of evergreens. As the traveller treads his way amongst the rocky scenery of Woo-e-shan, he is continually coming upon these plantations, which are dotted upon the sides of all the hills. The leaves are of a rich dark green, and afford a pleasing contrast to the strange and often barren scenery which is every where around. The natives are perfectly aware that the practice of plucking the leaves is very prejudicial to the health of the tea-shrubs, and always take care to have plants in a strong and vigorous condition before they commence gathering. The young planta-

tions are generally allowed to grow unmolested for two or three years, or until they are well established and are producing strong and vigorous shoots; it would be considered very bad management to begin to pluck the leaves until this is the case. Even when the plantations were in full bearing I observed that the natives never took many leaves from the weaker plants, and sometimes passed them altogether in order that their growth might not be checked.—*Tea Districts, page* 259.

The Tea plant.—I must now make some observations upon the tea-plant itself. It has already been remarked that two tea-plants, considered to be distinct varieties, are met with in China, both of which have been imported into Europe. One, the Canton variety, is called *Thea bohea;* the other, the northern variety, is called *Thea viridis.* The former produces the inferior green and black teas which are made about Canton, and from the latter are made all the fine green teas in the great Hwuy-chow country and in the adjoining provinces. Until a few years back it was generally supposed that the fine black teas of the Bohea hills were also made from the Canton variety, and hence its name. Such, however, is not the case. When I visited Foo-chow-foo for the first time in 1845, I observed that the tea-plant in cultivation in that neighbourhood was very different from the Canton variety, and apparently identical with the *Thea viridis* of Chekiang. Foo-chow-foo was not a very great distance from the Bohea hills, and I had good reasons for believing that the Bohea plant was the same as the Foo-chow one; but still I had no positive proof. The tea-plant is multiplied by seed like our hawthorns, and it is perfectly impossible that the produce can be identical in every respect with the parent. Instead therefore of having one or two varieties of tea-plant in China, we have in fact many kinds, although the difference between them may be slight. Add to this, that the seeds of this plant are raised year after year in different climates, and we shall no longer wonder that in the course of time the plants in one district appear slightly different from those of another, although they may have been originally produced from the same stock.—*Fortune, Tea Disirict, page* 284. For these reasons I am of opinion that the plants of Hwuy chow and Woo-e are the same species, and that the slight differences observed are the results of reproduction and difference of climate. With regard to the Canton plant, both in constitution and habit, it too may have originally sprung from one and the same species.

These changes however, do not alter the commercial value of those plants found cultivated in the great tea-countries of Fokien and Hwuy-chow, where the finest teas are produced; for, while the tea-shrub may have improved in the course of reproduction in these districts, it may have become deteriorated in others. For this reason seeds and plants ought always to be procured from these districts for transmission to other parts of the world where it is desirable to grow tea.—*Fortune's Tea Districts, page* 285.

Cultivation at Hwuy-chow.—In the green-tea district of Hwuy-chow, and I believe in all other parts where the shrub is cultivated, it is multiplied by seeds. The seeds are ripe in the month of October. When gathered they are generally put into a basket, and mixed up with sand and earth in a damp state and in this condition they are kept until the spring. If this plan is not pursued only a small portion of them will germinate. Like the seeds of the oak and chesnut, they are destroyed when exposed to sudden changes in temperature and moisture. In the month of March the seeds are taken out of the basket and placed in the ground. They are generally sown thickly, in rows or in beds, in a nursery, or in some spare corner of the tea-farm, and sometimes the vacancies in the existing plantations are made up by sowing five or six seeds in each vacant space. Page 91. When the young plants are a year old they are in a fit state for transplanting. This is always done at the change of the monsoon in spring, when fine warm showers are of frequent occurrence. They are planted in rows about four feet apart, and in groups of five or six plants in the row. The distance between each group or patch is generally about four feet. The first crop of leaves is taken from these plants in the third year. When under cultivation they rarely attain a greater height than three or four feet.—*Fortune, Tea Districts, page* 91. When the winters are very severe the natives tie straw bands round the bushes to protect them from the frost, and to prevent it and the snow from splitting them.

Tea Picking or Tea Harvest.—Mr. Fortune says, I made Ayukas temple my head-quarters for several days after the events took place which I have related in the previous chapter. My time was now fully occupied in visiting all the tea farms in the neighbourhood, and in getting information concerning the cultivation and manufacture of tea. It was the harvest-time for the principal crop of the season, and the natives were observed on every hill-side busily engaged in gathering the leaves. These tea gatherers were generally seen in small groups consisting of from eight to twelve persons. One old man was usually at the head of each group, the others being women and children. Each had a small stool formed like the letter T, but broad of course at the top, for sitting on while gathering the leaves on the lower sides of the bushes. The foot stool being pointed, it was easily forced into the ground in order to render it steady, and as easily drawn out and carried to a different spot. When these tea gatherers are hired they are not paid by the day, but by the quantity of leaves they bring in

to their employers. In making inquiries on the point I found they were paid at the rate of four and five cash a catty, and that they were able to gather from thirty to forty catty a day. In other words, each was able to gather from forty to fifty three pounds of raw leaves per day, for which was received from 6d. to 9d., or thereabouts. But it is only very expert and well trained hands that can make such a sum as this, children and very old people make, of course, something considerably less. Wages of labourers in the tea districts of China range from 2d. to 3d. per day with their food, which is almost always furnished by the farmers and which may cost about 3d. or 4d. more, making the whole day's labour amount to 6d. or 7d. The food of this people is of the simplest kind—namely, rice vegetables and a small portion of animal food, such as fish or pork.—*A Res. among the Chin. p.* 41.

Scenting of Tea.—Having taken a passing glance at all these objects on entering the building, I next, says Fortune, directed my attention to the scenting process, which had been the main object of my visit, and which I shall now endeavour to describe. In a corner of the building there lay a large heap of orange-flowers, which filled the air with the most delicious perfume. A man was engaged in sifting them to get out the stamens and other smaller portions of the flower. This process was necessary, in order that the flowers might be readily sifted out of the tea after the scenting had been accomplished. The orange-flowers being fully expanded, the large petals were easily separated from the stamens and smaller ones. In 100 parts 70 per cent. were used and 30 thrown away. When the orange is used, its flowers must be fully expanded, in order to bring out the scent; but flowers of jasmine may be used in the bud, as they will expand and emit their fragrance, during the time they are mixed with the tea. When the flowers had been sifted over in the manner described they were ready for use. In the mean time the tea to be scented had been carefully manipulated, and appeared perfectly dried and finished. At this stage of the process it is worthy of observing that, while the tea was perfectly dry, the orange-flowers were just as they had been gathered from the trees. Large quantities of the tea were now mixed up with the flowers, in the proportion of 40lbs of flowers to 100 lbs. of tea. This dry tea and the undried flowers were allowed to lie mixed together for the space of twenty-four hours. At the end of this time the flowers were sifted out of the tea, and by the repeated sifting and winnowing processes which the tea had afterwards to undergo they were nearly all got rid of. Sometimes a few stray ones are left in the tea, and may be detected even after it arrives in England. A small portion of tea adheres to the moist flowers when they are sifted out, and this is generally given away to the poor, who pick it out with the hand. The flowers, at this part of the process had impregnated the tea leaves with a large portion of their peculiar odours, but they had also left behind them a certain portion of moisture which it was necessary to expel. This was done by placing the tea once more over slow charcoal-fires in basket sieves prepared for the purpose of drying. The scent communicated by the flowers is very light for some time, but, like the fragrance peculiar to the tea leaf itself, comes out after being packed for a week or two. Sometimes this scenting process is repeated when the odour is not considered sufficiently strong, and the head man in the factory informed me he sometimes scented twice with orange-flowers and once with the "Mo-le" (Jasminum sambac). The flowers of various plants are used in scenting by the Chinese, some of which are considered better than others, and some can be had at seasons when others are not procurable. I considered it of some importance to the elucidation of this subject to find out not only the Chinese names of these various plants, but also, by examining the plants themselves, to be able to give each the name by which it is known to scientific men in all parts of the world. The following list was prepared with great care, and may be fully relied upon. The numbers prefixed express the relative value of each kind in the eyes of the Chinese and the asterisks point out those which are mostly used for scenting teas for the foreign markets in the order in which they are valued. Thus the "Mo-le" and the "Sieu-hing" are considered the best and so on:—

1 Rose scented (Tsing moi-qui-hwa).
1 or 2 plum double (Moi-hwa)
2 *Jasminum sambac (Mo-le-hwa)
2 or 3 *Jasminum paniculatum, (Sieu-hing-hwa).
4 *Aglaia odorata, (Lan-hwa-or yu-chu-lan).
5 Olea fragrans (Kwei-hwa).
6 *Orange (Chang-hwa).
7 *Gardenia florida (Pak-sema-hwa).

It has been frequently stated that the Chloranthus is largely used. This appears to be a mistake, originating, no doubt, in the similarity of its Chinese name to that of Aglaia odorata. The Chloranthus is called "Chu-lan," the Aglaia "Lan" or "Yu-chu-lan." The different flowers which I have just named are not all used in the same proportions. Thus, of orange-flowers there are 40 lbs to 100 lbs. of tea; of Aglaia there are 100 lbs to 100 lbs.; and of Jasminum sambac there are 50 lbs. to 100 lbs. The flowers of the Sieu-hing (Jasminum paniculatum) are generally mixed with those of the mo-le (Jasminum Sambac), in the proportion of 10 lbs. of the former to 30 lbs. of the latter, and the 40 lbs. thus produced are sufficient for

100 lbs. of tea. The "Kwei-hwa" (Olea fragrans) is used chiefly in the northern districts as a scent for a rare and expensive kind of Hyson Pekoe—a tea which forms a most delicious and refreshing beverage when taken a la Chinoise without sugar and milk. The quantity of flowers used seemed to me to be very large; and I made particular inquiries as to whether the teas that are scented were mixed up with large quantities of unscented kinds. The Chinese unhesitatingly affirmed that such was not the case, but, notwithstanding their assertions, I had some doubt on this point. The length of time which teas thus scented retain the scent is most remarkable. It varies, however, with the different sorts. Thus the Olea fragrans tea will only keep well for one year, at the end of two years it has either become scentless, or has a peculiar oily odour which is disagreeable. Teas scented with orange blossoms and with those of the Mo-le will keep well for two or three years, and the sieu hing kinds for three or four years. The Aglaia retains the scent longer than any, and is said to preserve well for five or six years. The tea scented with the Sieu hing is said to be most esteemed by foreigners, although it is put down as second or third rate by the Chinese. Scented teas for the foreign market are nearly all made in Canton and are known to merchants by the names of "scented Orange," "Pekoe," and "scented Caper." They are grown in and near a place called Tashan, in the Canton province. Mr. Walkinshaw informs me that other descriptions of tea, both black and green, have been scented for the English market, but have been found unsuitable. True caper is to black tea what the kinds called "imperial" and "gunpowder" are to green: it assumes a round, short looking form during the process of manipulation, and it is easily separated from the other leaves by sifting or by the winnowing machine. It is a common error to suppose that "imperial" or "gunpowder" amongst green teas, or "caper" amongst black ones, is prepared by rolling each leaf singly by the hand. Such a method of manipulation would make them much more expensive than they are. One gathering of tea is said to yield 70 per cent. of orange pekoe, 25 of souchong, and 5 of caper. The quantity of true caper would therefore appear to be very small; but there are many ways of increasing the quantity by peculiar modes of manipulation, as I shall afterwards show. In a large factory, such as this at Canton, there is, of course, a considerable quantity of dust and refuse tea remaining after the orange pekoe, caper, and souchong have been sifted out of it. This is sold in the country to the natives at a low price, and no doubt is often made up with paste and other ingredients into those ie teas which now-a-days find a market in England. Nothing is lost or thrown away in China. The stalks and yellow leaves which have been picked out by women and children are sold in the country; while the flowers which have done their duty in the scenting process are given to the poor, who pick out the few remaining tea-leaves which had been left by the sieve or winnowing machine. Some flowers, such as those of the Aglaia for example after being sifted out from the tea, are dried and used in the manufacture of the "fragrant Joss-stick," so much used in the religious ceremonies of the country. It appears from these investigations that many kinds of fragrant flowers besides those used by the Chinese would answer the purpose equally well, and therefore in places like India, where tea is likely to be produced upon an extensive scale, experiments in scenting might be made with any kinds of fragrant jasmines, daphnes, aurantiaceous or other plants of a like kind indigenous to the country. It will be observed from the description just given that the method of scenting teas, like most of the arts in China, is exceedingly simple in its nature and most efficient. It used to be said by those who knew nothing about the matter, that "the flowers were put over a slow fire, with the tea in a separate basket above them, and so the fire drove the scent from the flowers into the tea." Knowing the immense capacity which dry tea has for moisture of any kind, how much more simple and beautiful is the process of allowing it to lie for a space of time mixed up with undried flowers! A few years ago I published a description of the Chinese mode of yielding green teas to suit our depraved tastes in Europe, and particularly in America, where they are largely consumed. Scenting teas is a very different thing, and nothing can be urged against the taste for them. That this is so in the eyes of the Chinese may be gathered from the fact that, while they dye their teas, not to drink, but only to sell, they consume and highly appreciate these scented ones. The price paid for flowers used in the scenting process varies, like everything else according to the demand or supply in the market. In 1854 and 1855, it was about seventeen dollars per pecul, but sometimes as much as thirty dollars are paid for the same quantity. In former years,—ten or twelve years ago,—as much as sixty dollars per pecul used to be paid for flowers. This information was given me some time after I had been examining the method of scenting in the Honan factory, and by another manufacturer and confirmed me in the opinion I had then formed, namely, that after the tea is once scented with the proportions of flowers mentioned above, it is mixed up with large quantities of unscented tea. Were this not so, the large quantity of flowers used would render the tea much more expensive than it really is. Upon making further inquiries, of different individuals and at different times, I found that my surmises were correct. The results of the information

thus obtained were, that sixty pounds of this highly-scented mixture were capable of scenting one hundred pounds of unscented tea, and no doubt it is sometimes used in even smaller proportions, the kinds called "Caper" and Orange Pekoe are quite different in appearance from teas made in the great black-tea provinces of Fokien and Kiang-si as large quantities of these teas—indeed, the whole which are exported—are made up near Canton.—*A Residence among the Chi. page* 198.

Tea is well known to the natives of Lahore and Cashmere; but the latter, are the more fond of tea, and prefer the Thibetan product to the English or even Chinese, notwithstanding the absence of aroma and perfume. The Bokharians and Russians are also fond of tea, and use generally the genuine Chinese production. The former make a soup of tea, by boiling the leaves, and then adding milk, salt and butter; a great cupful of this with bread, forms their daily breakfast. Both Russians and Bokharians drink generally tea without sugar, and chew the leaves afterwards, so that nothing is lost—*Thirty-five years in the East by Dr. Honig, page* 358.

Adulterations.—Before noticing these, Dr. Hassall repeats some of the information previously given. He tells us that the tea plant is a hardy evergreen and leafy shrub which attains the height of from three to six feet and upwards. It belongs to the natural family Columniferæ (Ternstrœmiaceæ of Lindley,) which includes the Camellias. It is generally propagated from seed and the plant comes to maturity in from two to three years, yielding in the course of the season three and in some cases four crops of leaves. The first gathering takes place very early in the spring, a second in the beginning of May, a third about the middle of June, and a fourth in August. The leaves of the first gathering are the most valuable, and from these Pekoe tea which consists of the young leaf buds as well as black teas of the highest quality are prepared. Those of the last gathering are large and old leaves and consequently inferior in flavour and value. The leaves vary considerably in size and form; the youngest leaves are narrow convoluted and downy; the next in age and size have their edges delicately serrated with the venation scarcely perceptible: in those of medium and large sizes the venation is well marked, a series of characteristic loops being formed along each margin of the leaf and the serrations are stronger and deeper and placed at greater intervals.

Varieties of Tea.—The principal varieties of *black tea* are Bohea which is of the commonest and coarsest description, Congou, Souchong, Caper, and Padry Souchong and Pekoe, which are of the highest quality, the last consisting of the very young and unexpanded leaves and which when clothed with down constitute flowery Pekoe.

The principal varieties of *green tea* are Twankay, Hyson-skin, young Hyson, Hyson Imperial, and Gunpowder, which in green tea corresponds with flowery Pekoe in black. Imperial Hyson, and young Hyson consist of the second and third gatherings, while the light and inferior leaves separated from Hyson by a winnowing Machine constitute Hyson-skin, a variety in considerable demand amongst the Americans.

Tea plant.—There is according to most writers but one species of the tea-plant from which the whole of the above and many other varieties of tea are obtained, the differences depending upon soil, climate, weather, age of the leaves and mode of preparation. The plants from which black teas are prepared are grown chiefly on the slopes of hills and ledges of mountains, while the green tea-shrubs are cultivated in manured oils. Upon this circumstance many of the differences between the two varieties depend. Other differences are occasioned by the processes adopted in the preparation and roasting of the leaves. Thus while *black tea* is first roasted in a shallow iron vessel called a "kuo" and secondly in sieves over a bright charcoal fire, *green tea* does not undergo the second method of roasting but only the first that in the "kuo."

An important part of the manufacture of tea consists in the rolling the leaves, so as to impart to them, their characteristic twisted shape. This is effected by subjecting the leaves to pressure and rolling by the hands in a particular manner. The first effect of the application of heat to the leaves in the Kuo is to render them soft and flaccid. When in this state, they are removed from the vessel and submitted to the first rolling, an operation which, after the renewed action of the Kuo on each occasion, is three for four times repeated with superior teas, before the process is considered to be complete.

Scenting of Tea.—The following observations on the scenting of tea are extracted from Mr. Ball's "Account of the Cultivation and Manufacture of Tea in China."

The Chinese seem universally to agree in ancient as in modern times that no factitious scent can be given to tea which shall equals its natural fragrance: in short that only common Tea requires scenting. Those persons who have had the opportunity of drinking some of the finest kinds of Souchong will perhaps agree with the Chinese in these opinions. There are however many scented teas which so far from being inferior are even costly and much esteemed both in China and in Europe. Of these the Chu Lan, or Cowslip Hyson, may be considered the best. "The tea about to be scented must be taken hot from the last roasting (which immediately precedes the packing, and poured into a Hyson chest so as to form a layer of two inches in height from the bottom a handful or more of the fresh flowers (green) separated from the

stalks) is then strewed over the tea. In this manner the tea and flowers are placed in layers until the chest is quite full. The mouth of the canister is then closed and thus the tea remains for twenty-four hours. The proper proportion is three catties of flowers to one hundred catties of tea. The next day the chest is emptied when the tea and flowers are mixed together they then undergo the process of "Poey," about three catties being put into one sieve. The Poey Song is completely closed that the tea and flowers are thus roasted about from one to two hours or rather until the flowers become crisp. The flowers are then sifted out and the tea packed. If the tea require any further scenting, fresh flowers most be used and the process repeated as before. The tea thus prepared is then mixed with other tea in the proportion of one part of scented tea to twenty of plain. The whole is then slightly heated in a kuo (chao), and when packed constitutes the description of tea denominated in England Cowslip Hyson. Tea may be scented at any time with this kind of tea, but it must be previously heated or roasted about two hours. "The mode of scenting black tea differs from that of green, and, so far as I understand, there are two or three methods of performing this process. The Souchong or Caper teas, the Tetsiong and other teas of the Cowslip flavour, are also scented with the Chu Lan flower, *Chloranthus inconspicuus*. "After gathering, the flowers are separated from the stalk as before when some people dry them in the sun: but the best mode is to dry them in a Poey Song over a slow fire taking care not to change the yellow colour of the petals. When dried they are put aside to cool and are afterwards reduced to powder. If this powder, the scent of which is very powerful be sprinkled over the leaves previously to the last or two last roastings and rollings in the process of Poey, the tea will be highly scented, but this is an expensive mode, on account of the additional quantity of flowers required, and therefore is seldom practised. The usual mode is by sprinkling a small quantity of this powder over the tea during the last process of Poey, which take[illegible] previous to packing. A small white powde[illegible]ntly found in black teas of the caper flavour, cannot have escaped the observation of the tea dealers in England; this powder is that of the Chu Lan flower, whose colour has been changed to white in the process of Poey. "There is another scented tea of excellent flavour, which is made in small quantities and occasionally sent to foreigners as presents. This is a Souchong tea, scented with the flower of the 'Pae sheem' Gardenia florida.) "There are two other scented teas, also of fine flavour both Souchong teas, the one scented with the Quy-fa, or K[illegible]hoe (Olea fragrans) and the oth[illegible]he Moo-Ly-Hoa (Jasminum Sambac). Some people say that the three last teas are mixed with the flowers as the Hyson tea is mixed with the Chu Lan and are scented in the same manner. But others say that two sieves are placed in the Poey Song, the lower one containing the flowers and the upper one the tea. The latter is the mode in which the Pae Sheem tea to which I have previously alluded is scented. These are all the flowers with which I am acquainted which are employed to scent tea, but in the Keun Fang Pu, and Quang Tong Chy, or Canton Geographical History, many others are enumerated as eligible for that purpose. These works also observe that flowers so used should be full blown. M'Culloch, in his "Commercial Dictionary," draws an interesting parallel between the wine and the tea plant. "Considered as an object of agricultural produce the tea plant bears a close resemblance to the wine. In the husbandry of China it may be said to take the same place which the vine occupies in the southern countries of Europe. Like the latter its growth is chiefly confined to hilly tracts not suited to the growth of corn. The soils capable of producing the finest kinds are within given districts limited and partial. Skill and care both in husbandry and preparation are quite as necessary to the production of good tea as to that of good wine. "The best wine is produced only in particular latitudes as is the best tea, although perhaps the latter is not restricted to an equal degree. Only the most civilised nations of Europe have as yet succeeded in producing good wines, which is also the case in the East with tea, for the agricultural and manufacturing skill and industry of the Chinese are there unquestionably pre-eminent. These circumstances deserve to be attended to in estimating the difficulties which must be encountered in any attempt to propagate the tea-plant in colonial and other possessions. These difficulties are obviously very great and perhaps all but insuperable. Most of the attempts hitherto made to raise it in foreign countries were not indeed of a sort from which much was to be expected. Within the last few years however, considerable efforts have been made by the Dutch government of Java to produce tea on the hills of that island, and having the assistance of Chinese cultivators from Fokien, who form a considerable part of the emigrants to Java, a degree of success has attended them beyond what might have been expected in so warm a climate. The Brazilians have made similar efforts, having also, with the assistance of Chinese labourers, attempted to propagate the tea shrub near Rio de Janeiro, and a small quantity of tolerably good tea has been produced; but owing to the high price of labour in America, and the quantity required in the cultivation and manipulation of tea, there is no probability, even were the soil suitable, to the plant, that its culture can be profitably carried on in that country. It may perhaps succeed in

Assam where its culture is now being attempted, for labour is there comparatively cheap, and the hilly and table lands are said to bear a close resemblance to those of the tea districts of China; but we are not sanguine in our expectation as to the result." "All the black teas," says McCulloch, "exported (with the exception of a part of the Bohea grown in Woping a district of Canton) are grown in Fokien, a hilly, maritime, populous and industrious province, bordering to the north east on Canton. Owing to the peculiar nature of the Chinese laws as to inheritance, and probably, also in some degree to the despotic genius of the government, landed property is much sub-divided throughout the empire, so that tea is generally grown in gardens or plantations of no great extent. The leaves are picked by the cultivator's family and immediately conveyed to market, where a class of persons who make it their particular business purchase and collect them in quantities and manufacture them, in part, that is, expose them to be dried under a shed. A second class of persons commonly known in the Canton market as the tea merchants, repair to the districts where the tea is produced and purchase it in its half-prepared state from the first class and complete the manufacture by garbling the different qualities, in which operation, women and children are chiefly employed. A final drying is then given and the tea packed in chests and divided according to quality in parcels of from 100 to 600 chests each. These parcels are stamped with the name of the district grower, or manufacturer, exactly as is practised with the wines of Bordeaux and Burgundy, the indigo of Bengal and many others commodities; and from this circumstance get the name of chops, the Chinese term for a seal or signet. "The greater part of the tea is brought to Canton by land carriage, or inland navigation, but chiefly by the first, it is conveyed by porters, the roads of China in the southern provinces not generally admitting of wheel carriages, and beasts of burden being very rare. A small quantity of black tea is brought by sea, but probably smuggled, for this cheaper mode of transportation is discouraged by government, which it deprives of the transit duties levied on inland carriage. The length of land-carriage from the principal districts where the green teas are grown to Canton, is probably not less than 700 miles; nor that of the black tea over a mountainous country, less than 200 miles. The tea-merchants begin to arrive in Canton about the middle of October, and the busy season continues until the beginning of March, being briskest in November, December and January." There is another particular to which the comparison between the vine and tea plant made by Mr. M'Culloch may be extended, namely, the not less general use of the infusion made from the leaves of the tea plant by the people of various nations of both the old and new worlds. In China, as appears from the following extract, tea is the common beverage of the people. The late Sir George Staunton informs us that tea, like beer in England, is sold in public-houses, in every town, and along public roads and the banks of rivers and canals, nor is it unusual for the burdened and weary traveller to lay down his load, refresh himself with a cup of warm tea, and then pursue his journey." The wealthy Chinese simply infuse the leaves in an elegant porcelain cup, which has a cover of the same material; the leaves sink to the bottom of the cup, and generally remain there without inconvenience, though occasionally some may float or rise to the surface. To prevent this inconvenience sometimes a thin piece of silver, of filagree, or open work, is placed immediately on them. Where economy is necessary to be studied the teapot is used. The wealthy Japanese continue the ancient mode of grinding the leaves to powder; and after infusion in a cup, it is whipped with a split bambo, or denticulated instrument, till it creams, when they drink both the infusion and powder, as coffee is used in many parts of Asia."

Analysis of Tea.—The infusion made from tea contains gum, glucose or saccharine matter, a large quantity of tannin, and a peculiar nitrogenised principle called theine; this is identical with caffein, and upon its presence many of the properties of tea depend. The amount of gum and tannin contained in a given sample of tea afford data by which its quality may to some extent be determined.

Properties of Tea.—Lo Yu, a learned Chinese, who lived in the dynasty of Tang, A. D. 618 to 906, gives the following agreeable account of the qualities and effects of the infusion of the leaves of the tea plant.

"It tempers the spirit and harmonises the mind; dispels lassitude and relieves fatigue; awakens thought and prevents drowsiness; lightens or refreshes the body and clears the perceptive faculties." In Pereira's "Materia Medica" we find the following remarks relating to the properties of tea.—Its astringency is proved by its chemical properties. Another quality possessed especially by green tea, is that of diminishing the tendency to sleep. Tea appears to possess a sedative influence with regard to the vascular system. Strong green tea taken in large quantities, is capable in some constitutions of producing a most distressing feeling and of operating as a narcotic.

Adulteration of Tea. On the Use and Detection of Leaves other than those of the Tea plant.—It has been stated that the Chinese not unfrequently make use of the leaves of other plants besides those of tea and in particular the leaves of Camellia sasanqua and Chloranthus inconspicuus.

With La Veno Beno. This is an article which may be noticed in this place, being now very commonly sold under the above attractive title, to mix with tea. La Veno Beno consists of a coarse powder, of a reddish brown colour, intermixed with small fragments of a leaf which is stated to be that of sumach; to the taste the powder is astringent and bitter, and on analysis, it is ascertained to be composed in great part of coarsely powdered catechu.

Chinese Botanical Powder.—Like La Veno Beno, it is put up in packages, and sold at the same price; it consists of a coarse powder, of a reddish-brown colour and astringent taste, and is made up of a mixture of catechu and wheat-flour, the latter ingredient being added to reduce the strength of the catechu. *Its use is open to the same objections, sanitary and others, as La Veno Beno.*—From a consideration of the analysis of tea made by Dr. Hassall, it appears.—

1st. That not one of Thirty-five samples of black tea, as imported into England, contained any other leaf than that of the tea-plant.

2nd. That out of the above number of samples, twenty-three were genuine and twelve adulterated. The genuine teas were the Congous and Souchongs &c. and the adulterated teas, samples of scented Pekoe and scented Caper Chu'an or black gunpowder as well as imitations of these made from tea-dust.

3rd. That the adulterations detected consisted in facing, so as to improve the appearance of the teas, the surfaces of the leaves with black lead, an iridescent powder resembling mica, indigo, and turmeric, and in the manufacture of imitation tea out of tea dust, sand &c.

The second table which he framed affords conclusive evidence.

1st. That the fabrication of spurious black tea was extensively carried on at that time in the British metropolis, and in other towns of that kingdom.

2nd. That two processes of fabrication are adopted. In the first, the exhausted tea-leaves are made up with gum, and re-dried; black lead, and the mica-like powder, rose-pink, and carbonate of lime being sometimes added to bloom or face the leaves as well as sulphate of iron to darken the colour of the leaves and to give astringency. In the second, leaves other than those of tea (the kind matters but little) are used. These, after being dried, are broken down mixed with gum, catechu and made into a paste; the leaves are then re-dried and further broken down, and sometimes coated with gum. The spurious tea made from exhausted leaves is seldom sold alone, but is used either for mixing with genuine black, or is converted into green tea, in the manner to be described hereafter; while that made from British leaves and catechu is either mixed with black tea in the form of dust, or else is faced and bloomed, until it is made to resemble green tea.

From the Third table it appears,

1st. That out of twenty-four samples of black tea purchased of tea dealers and grocers resident in the British metropolis, twenty were genuine and four adulterated, the former being Congous and Souchongs, and the latter samples of scented Pekoe and scented Caper. It thus appears, that while the great bulk of the black tea used in England—viz, Congou and Souchong—as delivered to the consumer, is in a genuine state, the scented teas—viz, the Pekoes and Capers—are invariably adulterated. Lastly, that from the extensive fabrication of spurious black tea in Great Britain; it is necessary that the purchaser should be constantly on his guard.—*Hassell's Food and its adulterations, p.* 268.

Adulteration by artificial colouring in China.—The superintendent of the workmen managed the colouring part of the process himself. Having procured a portion of Prussian blue, he threw it into a porcelain bowl, not unlike a chemist's mortar, and crushed it into a very fine powder. At the same time a quantity of gypsum was produced and burned in the charcoal fires which were then roasting the teas. The object of this was to soften it in order that it might be readily pounded into a very fine powder in the same manner as the Prussian blue had been. The gypsum, having been taken out of the fire after a certain time had elapsed, readily crumbled down and was reduced to powder in the mortar. These two substances, having been thus prepared, were then mixed together in the proportion of four parts of gypsum to three parts of Prussian blue, and formed a light blue powder, which was then ready for use.—*Fortune's Tea Districts, page* 92. "This colouring matter was applied to the teas during the last process of roasting. About five minutes before the tea was removed from the pans—the time being regulated by the burning of a joss-stick, the superintendent took a small porcelain spoon, and with it he scattered a portion of the colouring matter over the leaves in each pan. The workmen then turned the leaves rapidly round with both hands, in order that the colour might be equally diffused. "One day an English gentlemen in Shanghae, being in conversation with some Chinese from the green-tea country, asked them what reasons they had for dyeing the tea, and whether it would not be better without undergoing this process. They acknowledged that tea was much better when prepared without having any such ingredients mixed with it, and that they never drank dyed teas themselves, but justly remarked that, as foreigners seems to prefer having a mixture of Prussian blue and gypsum with their tea, to make it look uniform and pretty, and as these ingredients were cheap enough the Chinese had no objection to supply them, especially as such teas always fetched a higher price.—*Ibid page* 93. I took some trouble to ascertain precisely the

quantity of colouring matter used in the process of dyeing green teas, not certainly with the view of assisting others, either at home or abroad, in the art of colouring, but simply to show green-tea drinkers in England, and more particularly in the United States of America what quantity of Prussian blue and gypsum they imbibe in the course of one year. To 4½ lbs. of tea were applied 8 mace 2½ candareens of colouring matter, or rather more than an ounce. In every hundred pounds of coloured green tea consumed in England or America, the consumer actually drinks more than half a pound of Prussian blue and gypsum. And yet tell the drinkers of this coloured tea that the Chinese eat cats, dogs, and rats, and they will hold up their hands in amazement, and pity the poor celestials." Two kinds of Prussian blue are used by the tea manufacturers one is the kind commonly met with, the other I have seen only in the north of China. It is less heavy than common Prussian blue, of a bright pale tint and very beautiful. Turmeric root is frequently employed in Canton, but I did not observe it in use in Hwuy-chow.—*Ibid page* 95. I procured samples of these ingredients from the Chinamen in the factory, in order that there might be no mistake as to what they really were. These were sent home to the Great Exhibition of 1851, and a portion of them submitted to Mr. Warrington, of Apothecaries' Hall, whose investigations in connexion with this subject are well known. In a paper read by him before the Chemical Society, and published in its 'Memoirs and Proceedings,' he says, "Mr. Fortune has forwarded from the north of China, for the Industrial Exhibition, specimens of these materials (tea dyes,) which, from their appearance, there can be no hesitation in stating are fibrous gypsum (calcined), turmeric root, and Prussian blue; the latter of a bright pale tint, most likely from admixture with alumina or porcelain-clay, which admixture may account for the alumina and silica found as stated in my previous paper, and the presence of which was then attributed possibly to the employment of Kaolin or agalmatolite."—*Fortune's Tea Districts, page* 95.

Green tea and its Adulterations.—According to most writers, there is but one species of tea plant from which the whole of the numerous varieties of tea both black and green are obtained, the differences in colour, quality &c., resulting from soil, climate, age of the leaves and mode of preparation. We have already pointed out in a very brief manner the principal difference in the cultivation and preparation of black and green teas. The plants from which black teas are prepared are grown chiefly on the slopes of hills and ledges of mountains, the leaves are obtained in three and in some cases even four gatherings, those of medium size and age being chiefly used for the great bulk of the black tea, viz. the congous and souchongs. They are dried either under covered sheds open at the sides, which is the best method, or else by exposure to the sun. This process is a somewhat lengthened one and during it a degree of fermentation is set up which is intimately associated with the colour, scent and flower of the leaves. Lastly the leaves are subjected to a double process of roasting first in a shallow iron pan termed a kuo, an operation which is repeated two or three times as may be necessary, and second in sieves called "poey longs" over a bright charcoal fire. The shrubs which furnish the leaves from which green tea is prepared are cultivated in manured or garden soils, the leaves are greener, more tender, and juicy, and two gatherings of them only are made, the first begins between the 20th of April and the 5th of May, and lasts for about ten or fifteen days, and the second at the summer solstice. After gathering, the leaves should be dried and roasted as soon as possible, in fact the same day, that is, before the slightest fermentation has had time to set in, all exposure to the air being unnecessary and to the sun injurious. During the roasting, which is repeated once or twice in the "kuo" only the second method viz: that in the poey long, not being practised the leaves are at the same time fanned to hasten the drying by dissipating the moisture which rises during the operation. The principal varieties of green tea are Twankay, an inferior description of Hyson, young Hyson; Hyson Skin, Gunpowder and Imperial; all these, except the Twankay, are obtained from unsorted Hyson or Mao Cha in the manner described by Mr. Ball.

In the analysis of black tea, several substances were found to be employed either for the purposes of facing and colouring the surface of the leaves or to impart astringency to the exhausted leaves. The substances ascertained were,

Starch,	Black Lead,
Gum,	Talc,
Catechu,	China clay,
Sulphate of Iron,	Soap-Stone,
Ro-e Pink,	Indigo,
Log wood,	Turmeric.

In addition to the above it has been ascertained that many other substances are employed. The colours used in the facing of green tree are usually three, yellow, blue, and white. The yellow and blue colours, when mixed, form a green, and white is added, either to lessen the intensity of the former colours, or else to give polish to the surface of the leaves. The following is a recapitulation of the more important results arrived at by Dr. Hassall in the course of his investigations. The chief points ascertained with regard to Black tea are,—

1st. That the principal black teas, namely, the Congous and Souchongs, arrive in England, for the most part, in a genuine state.

2nd. That certain descriptions of black tea as scented Orange, Pekoe and Caper are invariably adulterated, the adulteration in general consisting in the glazing of the leaves with plumbago or black lead; the Caper likewise being subject to admixture with other substances; as paddy husk, Lie tea and leaves other than those of tea.

3rd. That several varieties of a spurious Caper, or black Gunpowder, are prepared, which consist of tea dust, and sometimes the dust of other leaves and sand made up into little masses with gum, and faced or glazed with plumbago, Prussian blue, and turmeric powder. In some cases, these imitations are sold separately, but most frequently they are used to mix with, and adulterate the better qualities of Caper; viz. those which are made of tea faced with plumbago only. With respect to green tea, the principal conclusions are,

1st. That these teas, with the exception of a few of British growth and manufacture from Assam, are invariably adulterated, that is to say, are glazed with colouring matters of different kinds.

2nd. That the colouring matters used are in general Prussian blue, turmeric powder, and China clay, other ingredients being sometimes but not frequently employed.

3rd. That of these colouring matters, Prussian blue, or ferro cyanide of iron, possesses properties calculated to affect health injuriously.

4th. That, in Great Britain, there is really no such thing as a green tea—that is, a tea which possesses a natural green hue.

5th. That green teas, and more especially the Gunpowders, in addition to being faced and glazed, are more subject to adulteration in other ways than black teas, as by admixture with leaves, not those of tea, with paddy-husk, and particulary with Lie tea.

6th. Lie tea is prepared so as to resemble green tea, and is extensively used by the Chinese themselves to adulterate gunpowder tea; it is also sent over to Great Britain in vast quantities, and is employed for the same purpose by English tea-dealers and grocers.

The above are the more important conclusions as to the condition of black and green teas, as imported, but these articles undergo further deterioration in our own country.

Thus has been adduced evidence to show,

1st. That exhausted tea leaves are frequently made up with gum, &c., and resold to the public as genuine black tea, and, when artificially coloured and glazed, even as green tea.

2nd. That the substances employed in the colouring are in many cases very much more objectionable and injurious than those used by the Chinese, being often highly poisonous.

3rd. That it is no uncommon thing for tea, both black and green, to be fabricated from leaves not those of tea, and possessing no properties in commonwith the leaves of that plant.

4th. That black Lie tea is often coloured and extensively employed by English dealers and grocers for the adulteration of green tea.—*Hassall's Food and its adulterations, page* 291.

Shevaroy Hills, Madras.—The experiment of growing tea in the Madras Presidency has been often successfully tried, on a small scale. A number of plants supplied by government, through Dr. Wallich, were planted in the Shevaroy hills, about twelve or fourteen years since, and have thriven well: but though no doubt is entertained of the ease with which they could be propagated over a wide extent of country, no attempt has been made to give the cultivation a practical turn, or to make a cup of tea from the southern India tree.

Coorg.—In Coorg, too, the experiment has been tested with like results, so that sufficient warranty exists to justify trials on the largest scale.

Java.—The Dutch have introduced the tea plant in their rich and fruitful colony of Java. That island lies between the sixth and eighth degrees of south latitude. In 1828, the first experiment in the cultivation of tea was made in the garden of the Chateau of Burtenzorg, at Java, where 800 plants of an astonishing vigor, served as an encouragement to undertake this culture, and considerable plantations were made in many parts of the island. The first trials did not answer to the expectations, as far as regards the quality of the article, the astringent taste and feeble aroma of which caused the conjecture that the preparation of the leaf, and its final manipulation, are not exactly according to the process used in China. At present tea is cultivated in thirteen Residencies: but the principal establishment, where the final manipulation is made, is in the neighbourhood of Batavia. The tea which Java now furnishes yearly to the markets of the mother country, may be stated at from 200,000 to 300,000 pounds. It is intimated that the government intends to abandon this culture to the industry of private individuals, under the guarantee of equitable contracts. The mountain range, which runs through the centre of the island, is the most productive, because the tea gardens, extending from near the base, high up the mountains, reach an atmosphere tempered by elevation. The plant escapes the scorching heats of the torrid zone, and finds a climate, by height rather than by latitude, adapted to its nature. But the plant is not confined to lofty ridges. In the plains, the hedges and fences, if one may so call them, are all planted with the tea shrub, which flourish in greater or less perfection throughout the island. But, as has already been intimated, the equatorial latitudes are not the most auspicious for the vigorous growth of a plant that requires a temperature equally removed from the extremes of heat and cold, and the quality of the tea is as much affect-

ed by the climate as the growth of the plant. A considerable quantity of tea is annually shipped from Java to Europe; but the extension of the cultivation is no doubt checked by the exceeding fertility of the soil, and its adaptation to the growth of the rich products of tropical regions. Mr. Jacobson, inspector of tea culture in Java, has published at Batavia a work in three volumes, upon the mode of cultivating this plant, upon the choice of grounds, and the best processes for the preparation and manipulation of the leaves. This book, the fruit of many years of experience and care given to the subject, has been well received by the cultivators, who devote themselves to this branch of industry. If, by means of careful experiments and experience, the government succeed in conferring on the island of Java this important branch of commerce, she may hope to obtain brilliant results; at all events, it will open to the country a new source of prosperity and riches.—*Simmonds.*

(8075) TEAK, TECTONA GRANDIS. Verbenaceæ, Roxb. C. 6.

Teak, ENG.	Teak Chettoo, TEL.
Teak marum, TAM.	Sagwan, HIND.

A native of the mountainous parts of Malabar and of the mountains bordering on the banks of the Godavery, above Rajahmundry, the Pegu, Moulmein and Rangoon forests. This well known and far famed tree grows straight and lofty, with cross armed panicles of showy, white flowers. It seems to require 80 yards to attain perfection The wood is very hard, but easily worked; it is soon seasoned, and being oily, does not injure iron; and shrinks little. It is probably the most durable timber known, hence its value in shipbuilding. The Malabar Teak is considered the *best*, and is always most valued in Indian Government dock yards. A valuable report by Dr. Falconer on the Teak forests of the Tenasserim Coast, was published lately among the Selections, from the Records of the Bengal Government. The price of Teak-wood at present is 3 Rs. per cubic foot, double the ordinary rate. It is matter of regret considering the vast importance of teak timber to England, as a maritime nation, that the preservation of the teak forests was so long disregarded. (Wight No. 100, Mysore 2, Tinnevelly 2, 9, 63, 27, Coorg 11, Rajahmundry, Paulghaut 3, 23, 30, Bangalore 4, Mangalore 15 Travancore 64, 70, 254, Penang 130, 165, Canara 55.)—*M. E. J. R.* This most useful tree, on the Coromandel Coast, flowers in June and July and the seeds ripen in September and October. The wood of this tree has from long experience been found to be by far the most useful timber in Southern Asia; it is light, easily worked and at the same time both strong and durable. That which grows on the mountains in the vicinity of the Godavery is occasionally beautifully veined and mottled. For ship building purposes, Teak is superior to every other sort of wood, being light, strong, and durable, whether in or out of water. Pegu, produces the largest quantity and their navigable rivers enable the natives to bring it down to the sea ports at a cheap rate, which enables them to undersell that of any other part of India. This timber has been found ill adapted for Gun carriages. Indeed when it is observed how easily it splits, it is surprising that it had been for so many years applied to this purpose, especially for the felloes.

Godavery Teak.—The great depot for the Godavery teak is Coringa where many vessels are built, yet there it is found more profitable to plank vessels chiefly with teak brought from the opposite coast. Either from want of means of transport or the force of habit, the wood cutters about the Godavery cut short almost every log to a length of eighteen or twenty feet, and cut away one half of the thickness of the finest logs; leaving three projecting pieces which are pierced for staples for convenience in lashing either to the yokes of the buffaloes or for conveying it from the forest or in rafts on the water. Some years since a wise enactment was passed for the Tenasserim provinces limiting a person cutting trees according to his means of transporting them. The Messrs. Palmer of Hyderabad at one time farmed teak forests, and sent down some very fine timber, but the speculation was given up as their agent at Neelapully was unable to obtain their prices. Government might easily prevent the waste noted by charging an exportation duty on all timber so hacked. It is strange that this waste is only in the teak timber, and not in inferior descriptions. In the Masulipatam and Rajahmundry district the timbers are classed as Tanabees 18 to 20 ft × 18 in. × 10 in. Toondoors 14 ft × 12 in diameter.—*Rohdes, M. S. S.*

At another place Mr. Rohdes observes, Teak is brought in large quantities from the country bordering the Godavery and its tributaries, and though the large logs are hacked away, when the Palmers of Hyderabad farmed the teak forests several of the finest trees felled by them within 100 miles of the coast remained from want of sufficient means of transport. *By a heavy duty on all logs hacked to waste, to the extent much of the timber is, Government would do much to preserve the supply.* Mr. Rohdes has seen several enormous teak logs washed down, clearly showing that even the banks of the rivers have not yet been deprived of their finest timber. A great deal of good timber, from 8 to 12 inches diameter, is brought to Masulipatam by carts returning from Nagpoor, the Chandah road to which runs for many miles through teak forests. The average price of teak at Rajahmundry is under 8 annas a cubic foot. It is classed as,

Tanchees, say 18 feet × 20 in × 8.
Toondoos 15 ,, × 12 in diameter.
Sirambees, 18 ,, × 8 in.

The Godavery teak varies much in density: much of it is finely veined; generally it is heavier than the Rangoon teak, but not equal to some from the Malabar Coast. In Ceylon, the Dutch largely planted teak, which has attained considerable size. Teak seems to require about 80 years to obtain perfection, but after 20 years a teak plantation would probably yield a valuable return in thinning.—*Rohdes.*

Malabar Teak.—Upon the whole, the Malabar teak seems the best. That of Rangoon is lighter and more open in the grain and is preferred for masts and spars. The dark or heavy teak of the mountains bordering on the Godavery is very little if at all inferior to the Malabar, but a good deal of the Godavery teak is very open grained. The logs brought to market are always irregular in shape. Where strength without any regard to size and shape is required, the small heavy logs brought down by return bullock carts to Masulipatam may be used. Major Campbell's experiments show the weight of a cubic foot to vary in the several specimens from 52 to 37 lbs, practical value of S. 92 to 50. Mr. Rohdes has frequently been struck with the want of strength in logs apparently sound, but has generally found the darkest veined wood the strongest. It is said that a varnish is extracted in Pegu from this tree.—*Rohdes, M.S.S.*

Tenasserim Teak —Teak is the staple timber of the Tenasserim Provinces, and from its abundance in Province Amherst, and its valuable property of being impervious to the white ants, it is used in Maulmain almost exclusively, both for building purposes, and for furniture. In 1848, eighteen thousand tons of this timber were exported, and Mr. O'Riley estimated that more than three thousand tons were used for home consumption; the total value of the whole falling little short of a million of rupees.—*Mason.*

The teak tree is of rapid growth, and the trunk grows erect, to a vast height, with copious spreading branches. The wood of the teak tree is by far the most useful timber in India; it is light, easily worked, and, though porous, it is strong and durable; it requires little seasoning, and shrinks very little: it affords tar of good quality and is rather of an oily nature, therefore does not injure iron, and is the best wood in this country for ship-timber, house carpentry, or any other work where strong and durable wood is required. Malabar teak is esteemed superior to any other in India, and is extensively used for ship-building at Bombay. It grows in the teak forests along the western side of the Ghaut Mountains, and the contiguous ridges, where the numerous streams afford water carriage for the timber. There a variety, says Dr. Roxburgh, which grows on the banks of the Godavery, of which the wood is beautifully veined, closer grained, and heavier than that of the common teak tree; this kind is well adapted for furniture. The cohesive force of teak wood varies from 13,000 to 15,000 pounds per square inch; the weight of its modulus of elasticity is 2,167,000 pounds per square inch, according to Mr. Barlow's experiments; and the weight of a cubic foot seasoned, varies from 41 to 53 pounds. Representing the strength of oak by 100,

	that of teak will be,	109
Stiffness of oak by 100,	,,	126
Toughness of oak by 100,	,,	94

From which it appears, that it is much superior to oak in these properties, except in toughness; but it is to be remembered, that these proportions, are drawn from two or three experiments on teak, and most probably these were tried on very select specimens; whereas those for oak from a mean specimen, selected from pieces of oak of various qualities.—(*Tredgold?*) Teakwood, says Tredgold, is the produce of the Tectona grandis, a native of the mountainous parts of the Malabar coast, and of the Rajahmundry Circars as well as of Java, Ceylon, and the Moulmein and Tenasserim Coasts. It grows quickly, straight, and lofty, the wood is light and porous, and easily worked, but it is nevertheless strong and durable; it is soon seasoned, and being oily, does not injure iron, and shrinks but little in width. Its colour is light brown, and it is esteemed the most valuable timber in India for shipbuilding and house-carpentry, it has many localities. The Malabar teak which grows on the western side of the Ghaut mountains is esteemed the best and is always preferred at Government dock-yards. Teak is considered a more brittle wood than the Saul or the Sissoo. In 25 years, the teak attains the size of two feet diameter, and is considered serviceable timber, but it requires 100 years to arrive at maturity. There is a variety, says Dr. Roxburgh, which grows on the banks of the Godavery in the Deccan, of which the wood is beautifully veined, closer grained and heavier than the common teak tree, and which is well adapted for furniture. Some of the old trees have beautiful burrs, resembling the Amboyna, which are much esteemed. I have an excellent specimen of the burr of the teakwood, through the kindness of Dr. Horsfield, of the East India House. Wood in general does not very perceptibly alter in respect to length; Teak, says Colonel Lloyd, is a remarkable exception. He found the contraction in length, in the beams of a large room he erected in the Mauritius, to be three quarters of an inch in 38 feet. The teak-wood when fresh has an agreeable odour, something like rose wood, and an oil is obtained from it. He adds, "The finest teak now produced comes from Moulmein and other

parts of Burmah ; some of this timber is unusually heavy and close grained, but in purchasing large quantities, care must be taken that the wood has not been tapped for its oil, which is a frequent custom of the natives, and renders the wood less durable." " At Moulmein, so much straight timber is taken and the crooked left, that thousands of pieces called shin logs," and admirably adapted for ship timbers, are left. Teak contains a large quantity of siliceous matter, which is very destructive to the tools. African teak does not belong to the same genus as the Indian teak ; by some it is thought to be a Euphorbiaceous, plant and by Mr. Don to be a Vitex.—*Tredgold.* Teak, says Edye, has been brought into use in the British navy at Bombay, Calcutta, and Cochin. The following is a list of the ships of war built of this timber :—

Ships of the Line.—Minden, Cornwallis, Melville, Malabar, Wellesley, Ganges, Asia, Bombay, Calcutta. Hastings.

Frigates.—Salsette, Amphitrite, Trincomalee, Seringapatam, Madagascar, Andromeda, Alligator, Samarang, Herald.

Sloops.—Victor, Cameleon, Sphynx, Cochin.

It has been considered by many, that a ship built of this sort of wood would last good from thirty to fifty years, for which time, report says, many ships have been known to run in India. The old Milford Bombay ship, in the country trade of India, was the oldest and best-conditioned ship that ever came under Mr. Edye's notice. She was, he says, built of teak-timber about thirty-five years before I saw her ; she had been constantly at sea, and only had a small repair during that period. She was built of the Malabar teak. It is generally considered that there are three sorts of teak. That sort which grows to a very large size is of an open, porous grain, and very much resembles Dantzic oak : it is found in the forests at the foot of the Ghats ; in valleys where the soil is deep and rich ; and on the banks of great rivers. On the bank of the Iruarri river, near the Ghauts, about eighty miles from Cochin, he caused a tree of teak to be felled. It was seven feet in diameter, and at seventy feet from the butt it was twenty-six inches in diameter. It was not durable as timber ; but for planks and boards, such as the native carpenters use, it is preferred to any other of the small knotty woods. It is a fact, he adds, which my experience in the county has taught me, that all teak-timber, above twenty inches in diameter at the butt, has the heart shake from end to end, and consequently, requires much care to convert it to use ; which should be done by a saw-cut into the heart of the wood and then either of the two parts might be used as timber or plank. But teak generally grows straight, and, consequently, for the timber of a large ship its curve crosses the grain of the wood : the shake runs through the timber on the outside at the head and heel, and, in the inside, it follows the curve in the middle, nearly breaking through to the surface. This shake, of four or five inches broad, and an inch or an inch and a half open in the heart of the timber, must be totally destructive to it ; as must have been the case in the Minden seventy-four gun ship.—The next sort of teak on the coast is that which grows in the forest of the Ghats. It is curved, hard and knotty, as the soil is not deep, its bed being rocks. This timber resembles in growth and appearance the English oak ; its weight is very considerably more than that which grows to the large size ; and the texture and durability of this timber is well known to those who are acquainted with the grain of woods.—Teaks will be found to differ in weight from thirty-nine pounds six ounces to fifty-two pounds fifteen ounces the cubic foot, when seasoned ; but the heaviest, when green, that I have found, were only fifty-seven pounds nine ounces the cubic foot. I am told some of the teaks from the Cochin forest weigh as much as sixty pounds the foot, when green. The third sort of teak is procured from Pegu, Rangoon, Ava, and the Burmese territories. For ship building it is very inferior to that of Malabar. It is generally considered, by persons unacquainted with the nature of timber, that " the teak from that country is superior to any other in India," this is acknowledged by competent persons so far only as regards the size of the tree, and the free and clear grain of the wood. There can be no doubt that it is better for purposes of house-building, and the general uses of the native carpenter, from the ease he finds in working it. This timber, as well as that before described, grows on a rich deep soil, and, consequently, its maturity is rapid and its dimensions large ; but the texture of the wood is as different from that of the forests of the Ghauts, as the American and Dantzic are from the English oak. At Rangoon and Pegu this timber is split in the heart shake into two parts, which the natives call shimbins, and this shews the freeness of the grain of the wood. These pieces are priced according to their size ; and this sort of teak is better known to the merchants and captains of the country-trade than any other, on account of its use for the repairs of vessels, or as sea-shore timber. The teak may be said to be the most valuable tree in India. It produces a good oil, which is used with paint as a substitute for Linseed-oil ; and which also makes a good varnish for paint or wood, and is known generally by the name of wood oil. The leaf of this tree is large and round, in shape resembling a cabbage leaf, about ten inches in diameter, but very thin, although its fibres are strong. The blossoms and berries are produced in large bunches : when in bloom, they may be compared to hops ; when in seed, as to size, to a bunch of grapes. The nut is of a dark russet brown, and very

hard: when ripe, it falls to the ground and plants itself. A forest patch of teak, when in full bloom, has much the appearance of a field of ripe corn when viewed from a distance, with a few spots of green interspersed; by this appearance the native hill people discover the trees of teak at this season, and cut around their roots to prevent the sap from ascending the next year. The persons who work the forests of teak on the side of the hill are thus able to distinguish at a distance those trees from the others, and cut them down for floating to the depot, which can only be done at the setting in of the monsoon, when the rapids fill the nalas; and then the tremendous torrents dash whatever may be thrown into them from one fall to another, from heights of fifty feet at a fall, until at last it reaches the depot, having been brought down by a circuitous route of one hundred miles, from a height of from 1000 to 2000 feet above the level of the sea. Much might be said on the uses and durability of teak and foreign timber, but it will be desirable to postpone that until its practical uses have been proved. There cannot be a doubt that the climate and temperature of its native atmosphere is the most favourable to its durability. Its value, for the purposes of ship-building, does not consist merely in its durability; a still greater advantage is, that the ship is at all times ready for service, while ships of European wood, constructed with oak and fir, are constantly warping and crazy, and in forty-eight hours after the caulking of the topsides are frequently as leaky as before: the health of the crew suffers, in consequence, at the change of the monsoon, from exposure to the damps of a tropical climate; and also, from this cause, the carpenter's crew are kept fully employed. But the teak ship, when well caulked, remains dry and comfortable to the crew; and is always an efficient ship for service. The many contradictory reports of sailors on the state of ships of war on foreign stations, is to be placed to the want of knowledge of the true state of facts. It is well known in the dockyards that, by a continual caulking of the sides or decks of a ship, the wood is so completely compressed on the seams and edges of the plank by the caulking iron, that the oakum is forced through the seam into the ship, and that that seam can never be again caulked tight. From this cause the oakum in the seam becomes wet and rotten; and the ship's crew are exposed to the injurious effects of inhaling the putrid air through the openings of the ship's timbers. The confined state of a ship under hatches in a tropical climate, is well known to all who have been on board one in the heavy tropical rains and gales of wind when the monsoon sets in, and which last for days and weeks together.—*Edye, Malabar and Canara.* See TECTONA.

(8076) TEAK WOOD OIL. An opaque dull ash coloured oil, under this name, is procurable in most of the large Bazars of India; when allowed to rest for some time, it separates into two layers, an upper or dark coloured clear stratum and a lower and more solid deposit. Its chief use is for applying to woodwork of all sorts, either alone as a natural varnish, or in combination with certain resins.—*M. E. J. R.*

(8077) TEAL, the common name of a Natatorial Bird belonging to the family *Anatinæ*. This bird is the *Querquedula crecca*, Steph.; the *Anas crecca*, Linn. It is one of the smallest of the *Anatidæ*, and most beautiful of ducks. It is the Sarcelle, Petite Sarcelle, Cercelle, Cercerelle, Alebrande, Garsote, and Halebran, of the French; Cercedula, Cercevolo, Scavolo, Sartella, Anitrella, and Anitra d'Inverno, of the Italians; Spiegel-Entlein and Kriekente of the Germans; Winter Taling of the Netherlanders; Arta and Kræcka of the Swedes; Kestelort-And of the Norwegians; Krik-And of the Danes; Cor Hwyad and Brach Hwyad of the Welsh. This species is one of the most delicate of the ducks. Willughby remarks that, for the taste of its flesh and the wholesome nourishment it affords the body, it "doth deservedly challenge the first place among those of its kind." In the 'Portraits d'Oyseaux' (1557), the following quatrain celebrates its excellence, and alludes to its habits:—

"Bien peu souvent se plonge la sarcelle
Entre deux eaux, de lequelle la chair
Est delicate: aussi couste elle cher
Autant qu'oyseau qui soit petit comme elle."

Accordingly we see it holding a high place in ancient feasts. We find it among the 'goodly provision' at the banquet given at the enthroning of George Nevell, archbishop of York, in the reign of Edward IV.: 'Mallardes and Teales, 4000. The price in the Northumberland Household Book is—'Teylles, 1*d.*,' mallards being 2*d.*—*Eng. Cyc.*

(8078) TEASEL, FULLER'S THISTLE, OR TEAZLE.

Chardo a carder, FR.	Weberdistel, Kratzdistel, GER.
Cardon da Cardare, IT.	Cardencha, Cardo peinador, SP.

This plant, which is cultivated in the North and West of England, is of considerable importance to clothiers, who employ the crooked awns of the heads for raising the nap on woollen cloths, &c. (*McCulloch*)—*Faulkner.*

(8079) TECOMA, a genus of plants belonging to the natural order *Bignoniaceæ*. It has a companulate 5-toothed calyx, a short-tubed corolla with a companulate throat, and a 5-lobed bilabiate limb; 4 didynamous stamens with a sterile filament of a fifth; a bilamellate stigma; a sillique-formed 2-celled capsule, having the dissepiments contrary to the valves; the seeds winged, disposed in 2 rows.

The species are erect trees or shrubs or scandent plants, with unequally pinnate or digitate simple leaves with terminal panicles, and yellow or flesh-coloured flowers. They are natives of the Old and New World in tropical and sub-tropical climates. They are all elegant plants, and well worthy of cultivation. Several species of *Tecoma* have reputed medicinal virtues. *T. speciosa* is said to be a useful diuretic, also a cathartic. *T. impetiginosa* and *T. Ipe* contain large quantities of tanning.—*Eng. Cyc.*

(8080) TECOMA CAPENSIS. An elegant creeping plant with orange colored flowers well adapted for covering a wall or running up a trellis work, grown from seed in common garden soil.—*Riddell.*

(8081) TECOMA JASMINOIDES. This plant is cultivated in the same way as the former. The color of the flowers pink.—*Riddell.*

(8082) TECOMA RADICANS is a climbing glabrous plant with rough rooting branches. It grows against a wall by throwing out roots from its branches in the same manner as ivy. It has large flowers, which are called Trumpet-Flowers. —*Eng. Cyc.*

(8083) TECOMA STANS is a small tree, or ornamental garden shrub. Its roots are reputed diuretic, Hort Garden 6.—*M. E. J. R.*

(8084) TECTONA, a genus of Plants belonging to the natural order *Verbenaceæ*. It is characterised by having a 5-6-toothed calyx, which becomes inflated over the growing pericarp; corolla 1-petalled, 5-6-cleft; stamens 5, but often 6; germ superior, 4-celled; cells 1-seeded, attachment central; drupe obtusely 4-sided, woolly, spongy, dry, hid in the calyx. Nut hard, 4-celled. Seed solitary; embryo erect without perisperm.—*Eng Cyc.*

(8085) TECTONA. *Species.*

Oomy takoo marum, TAM.

Dr. Wight says of this I am as yet uncertain whether to view this as a variety or distinct species of teak. Specimens tested here proved very inferior in strength to the true teak, breaking with a weight of only 300 lbs., while the other sustained above 400.—*Wight.*

(8086) TECTONA GRANDIS.

Teak tree, ENG. | Takoo chettoo, TEL.
Sagwan, HIND. | Take marum, TAM.

The only species is the Teak-Tree, which grows to an immense size, and is remarkable for its very long leaves, which are from 12 to 24 inches long and from 8 to 16 inches broad, and are compared by oriental writers to the ears of the elephant. The best teak-timber for ship-building was supplied to Bombay from the mountains of the Malabar Ghauts, where the tree is found rather in detached clumps, of some extent however, than in extended forests. It is also found on the mountainous parts of the Coromandel coast, along the banks of the Godavery up to Poloonsha. It proceeds far into the interior of India, and may be seen in the mountains of Bundulcund, in the form however of only a moderate-sized shrub. Dr. Roxburgh introduced the Teak into the low grounds of the Circars as early as 1790, and Lord Cornwallis and Colonel Kyd planted it in Bengal about the same time. The Calcutta Botanic Garden contains a number of these trees. From the Saharunpore Botanic Garden, in 30° 9' N. lat. (where, its buds being covered with scales, it is enabled to resist cold, besides its leaves falling and giving it a season of rest), the tree has been spread along the Doab Canal; the whole of the intermediate country is suited to its cultivation, and the East India Company have ordered the Malabar forests to be preserved. The most extensive forests are however those extending along the banks of the Irrawady, especially in Pegu —*Eng. Cyc.* See TEAK.

(8087) TECTONA GRANDIS. *Var.* HUL TEAK. Wynaad about Sultan's Battery, scarce; considered superior to the common Teak.—*McIvor. M. E.*

(8088) TECTONA HAMILTONIA HAMILTON TEAK. This is an inferior species of teak that grows on the banks of the Irrawaddy; and from native descriptions, appears to be found in the province of Yay.—*Mason.*

(8089) TECTONA TERNIFOLIA, of Tenasserim.—*Mason.*

(8090) TEJBAL.

Tejbal, GUZ. HIND. PERS.

The seeds and capsules of the *Xanthoxylum hostile*, which are employed by the natives of northern India as a remedy for the tooth-ache, and also for intoxicating fish. They have a warm, spicy, pepper-like pungency, a property which is participated in by the bark, and other parts of the tree.—*Faulkner.*

(8091) TEJPATA. LEAVES of LAURUS or CINNAMOMUM. Malabathrum, the folia Malabathri of the ancients.—*Ben. Phar.*

(8092) TELEKIA, COMPOSITÆ.—This plant bears a yellow flower, and grows in any common garden soil.—*Riddell.*

(8093) TELINI, INDIAN BLISTERING FLY. Meloe or Mylabris Cichorii. The wing coverts are marked with large spots of light brown alternating with deep blue. Another blistering fly is small, steel blue, Cantharis Violacea.—*Ben. Phar.*

(8094) TEMIA (Le Vaillant), a genus of Perching Birds, which, Cuvier observes, M. Vieillot has changed into *Crypsirina*, and Dr. Horsfield into *Phrenotrix*, whilst M. Temminck arranges them under *Glaucopis*. Mr. Swainson thus characterises *Crypsirina*.—Bill shorter than the head, much compressed; the culmen considerably arched, and curved from the base. Nostrils small, basal, concealed by incumbent feathers, which are either soft or setaceous. Wings short, much rounded; the primaries hardly longer than

the secondaries. Tail feathers broad and obtuse. Feet moderate, arboreal. The middle toe and claw short, but as long as the tarsus; lateral toes unequal; hind toe and claw shorter than the tarsus. It is a native of India.

(8095) *Crypsirina vagabonda* (*vagabundo*) and *C. Temia* are among the species given as examples. The first of these is the *Pica vagabunda* of Gould ('Century of Birds from the Himalaya mountains'). Dr. Horsfield, who gives *Corvus varians* as the synonym of his *Phrenotrix Temia* (the Chekitut, or Benteot, of the Javanese), states that although not a rare bird in Java, his *Phrenotrix* is by no means familiar, and never approaches the villages and habitations like many others. ('Zoological Researches in Java.')—*Eng. Cyc.*

(8096) TENTUKIE, the Malayala name of a Ceylon tree which grows to about twelve or eighteen inches in diameter, twelve feet high: it can not be considered valuable. It is sometimes used by the natives for inferior and common purposes.—*Edye, Ceylon.*

(8097) TEPHRODORNIS (Swainson), a genus of Drongo Shrikes, *Dicrurinæ*. [LANIADÆ] —*Eng. Cyc.*

(8098) TEPHROSIA (from τεφρός, ash-coloured), the name of a genus of Plants belonging to the Papilionaceous division of the order *Leguminosæ*. The genus consists of shrubs or herbs, with usually unequally pinnated leaves, and lanceolate or subulate stipules distinct from the petiole. The flowers are white or purplish, arranged in racemes which are mostly axillary; the calyx is without bracts, 5-toothed, nearly equal; vexillum of corolla large, silky outside, and reflexed in a spreading manner; wings adherent to the keel; stamens separate or united in one or two parcels; legume mostly sessile, linear, compressed, many seeded, with the valves flat; seeds compressed. This genus at present includes 84 species, but it is probable that a more accurate investigation will result in making several genera of the present one. The American and Asiatic species are in some measure distinguished by their properties. In the former a narcotic poison is more frequently secreted; in the latter a colouring matter.—*Eng. Cyc.* Dr. Wight, in Icones gives Tephrosia incana, 371; sentiçosa, 370; spinosa, 372; and tinctoria, 388.

(8099) TEPHROSIA APOLLINEA. *Syn.* Galega apollinea. A native of Egypt. The leaflets are obovate, oblong, emarginate, silky underneath. They yield indigo when fermented, and are often mixed with the Alexandrian senna.—*O'Shaughnessy, page* 292. *T. Apollinea* is shrubby, and covered with a close pubescence; the leaflets are silky beneath, and in 2 or 3 pairs; the legume is 6 or 7-seeded, and rather pubescent. It is a native of Egypt, and yields a blue colouring-matter, which is used in dyeing.—*Eng. Cyc.*

(8100) TEPHROSIA PISCATORIA, the Fisher's Tephrosia, contains the narcotic principle of the genus, and is used in the East Indies for the same purposes as *T. toxicaria* is in the West Indies.—*Eng. Cyc.*

(8101) TEPHROSIA PURPUREA. GALEGA PURPUREA.

Poonkhie, SANS. | Surpunka, BENG.

A native of the sandy coast of Coromandel. The root is bitter, and given by the native practitioners in dyspepsia and chronic diarrhœa.—*O'Shaughnessy, page* 292.

(8102) TEPHROSIA TINCTORIA, the Ceylon Indigo, is a shrubby glabrous plant with 5 pairs of leaflets, silky and villous beneath; flowers purple or flesh-coloured, seated on axillary peduncles; straight pendulous legumes. This plant is a native of Ceylon, where it is called Anil. Its tissue yields a blue colouring-matter, which has the same properties as the indigo, and is used in Ceylon for the same purposes. There are other plants used in Ceylon for dyeing also, called Anil.—*Eng. Cyc.*

(8103) TERAI. At the north foot of the Khasia, in the heavily timbered dry Terai, stretching for sixty miles to the Burrampooter, it is almost inevitable death for a European to sleep, any time between the end of April and of November. Many have crossed that tract, but not one without taking fever: Mr H. Inglis was the only survivor of a party of five, and he was ill from the effects for upwards of two years, after having been brought to death's door by the first attack, which came on within three weeks of his arrival at Churra, and by several relapses. Temperature in September 77° to 80°; and in November 75° to 77°.—*Hooker Him. Jour. Vol.* I. *page* 266.

(8104) TEREBELLUM, a genus of *Mollusca* placed by Cuvier among his Pectinibranchiate Gasteropods, between *Ovula* and *Voluta*; by De Blainville among his *Angyostomata*, between *Conus* and *Oliva*; and by Rang between *Mitra* and *Ancillaria*. The fossil *Terebellum convolutum* is the type of Montfort's genus *Seraphs*.

(8105) TEREBELLUM SUBULATUM, a native of the East Indies, may be taken as an example of the recent species, and *T. convolutum* of the fossil forms.—*Eng. Cyc.*

(8106) TEREBINTACEÆ, a natural order of Dicotyledonous Plants constituted by Jussieu, and adopted by De Candolle, Arnott, Don, and other writers on systematic botany. Brown has however divided it into five orders, viz. Anacardiaceæ; Burseraceæ; Connaraceæ; Spondiaceæ; Amyridaceæ.—*Eng. Cyc.*

(8107) TERMINALIA (from 'terminus'), is the name of a genus of Plants belonging to the natural order *Combretaceæ*. The species of this genus consist of trees and shrubs, with alternate leaves, which are usually crowded together at the ends of the branches. The flowers are

destitute of petals, and are disposed in spikes, which are racemose and panicled; in the lower part of the spikes they contain both stamens and pistils, but in the upper part they contain only stamens; the limb of the calyx is campanulate, 5-cleft, with acute lobes; the stamens are 10 in number, arranged in two series, and are longer than the calyx; the ovary contains two ovules; the style is acute, and the fruit is drupaceous, containing only one seed. All the species are inhabitants of the tropical parts of Asia and America. They are numerous, and many of them are used in medicine and the arts. —*Eng. Cyc.* In the celebrated Myrobalans of ancient and eastern pharmacy, an astringency is the prevalent principle, although the fruits of *Terminalia Chebula* are gently laxative also. *T. Catappa* affords edible kernels, like almonds, and are named *badam*. *T. Benzoin* in the Mauritius gives a milky juice, which becomes fragrant as it dries, and is burned as incense in churches. —*O' Shaughnessy, page* 339.

(8108) TERMINALIA. *Species.* PENTAPTERA? Every member of the genus terminalia yields useful timber, and the chebula, and bellerica have been noticed as indigenous in Tenasserim. A still larger timber tree is common in the interior, whose winged fruit indicates its connection with Roxburgh's genus pentaptera.—*Mason.*

(8109) TERMINALIA ALATA, Ainslie. T. TOMENTOSA, Wall. Roxb. *Combretaceæ, Icon* 195.

Muddee, TEL.	Arjuna, SANS.
Maroodum Tree, ENG.	Kumbuk, CING.
Jungly karinj, HIND.	Kooroo-marthi mara, CAN.
Maroodum marum, TAM.	
Urjoon, HIND.	Junglee karing, DUK.

This tree often grows to a very large size. The wood of it is employed for long beams in house building. In the northern parts of Canara it is used for making boats and canoes.—*Ains. Mat. Med. p.* 209. Fruit glabrous, bark deeply cracked, astringent and febrifuge. As found in the Bazars its colour is reddish brown, taste astringent; in powder and with oil it is used in apthæ. (Roxb. Fl. Ind. ii. 440.)—*O' Shaughnessy, p.* 340.

The Bark.

Marndum Bark, ENG.	Muddie putta, TEL.
Marudum puttay, TAM.	Arjuna, SANS.

The bark as it appears in most of the Indian bazars is of a reddish brown colour, and has a strong but not unpleasant, astringent taste. In the Southern provinces, the powder of it in conjunction with Gingilie oil, is used as a valuable application for the kindatalie, (Apthæ of grown people) and the Akkirum, or Apthæ of infants. —*Ains. Mat. Med. p.* 58. In the Wynaad, Carroo-Marrathoo, Terminalia alata, is used for the same purposes as Ben teak, under which name it is frequently sold: common on the Western Ghauts and in Wynaad: wood not durable. —*McIvor.*

(8110) TERMINALIA ANGUSTIFOLIA. The leaves are linear-lanceolate, very thin at both ends, pubescent beneath; the petioles are also pubescent, and have two glands at their apex. This tree is a native of the East Indies, and was formerly called *Terminalia Benzoin*, as it yields on tapping a gum-resin very similar to benzoin, and possessing the same properties.—*Eng. Cyc.*

(8111) TERMINALIA BELLERICA. (BELERIC MYROBALAN.) *Combretaceæ*, Ill. 91.

Bulla, DUK.	Tam kaia marum or Tonda muram, also Tanikoi or tandee marum Cattoo eloopæ, TAM.
Beleyluj, ARAB.	
Bahira, SANS.	
Beheyra, HIND.	
Beleyleh, PERS.	
Tadi chettoo, TEL.	

A very large tree; common in Mysore and mountainous parts of India; has a straight trunk and spreading head; leaves deciduous about the beginning of the hot season, when the flowers appear; fruit round, covered with a grey silky down; common in the Deccan. The flowers have an offensive smell —*Riddell.* Of this tree, the wood is white and soft, and not much used. The kernel of the fruit is eaten by the natives. (Wight No. 11-99, Mysore 27, 18, Tinnevelly 47, Travancore 306, Cleghorn.)—*M. E. J. R.* Drupe oval, somewhat five-angled, size when dry of a gallnut, and dirty brown colour; size of a nutmeg, and fleshy when fresh, with a grey silky down, very astringent; kernels eaten, and deemed intoxicating; bark abounds in gum. Ainslie reckons the fruit as astringent, tonic, and attenuant. Dose one to two drachms. It is much used in the arts as an astringent, and as the basis of several colours.—*O'Shaughnessy, page* 341. It is abundant in the Kotah jungles and the wood is very hard.—*Irvine.* Wood said by Roxburgh to be durable, but not much used. In Malabar it is hollowed out for canoes, which however are said not to be lasting. It is not an uncommon tree in the Walliar Jungles, but is considered of no value there. Perhaps the tree called by the name of *Tanikai Marum*, or *tonda marum*, in Malabar, is the Terminalia Berryi, which also attains a large size, and is more nearly allied to the Curray Murdah, as belonging to the same section of the genus.—*Wight.* It furnishes a large and valuable timber. The wood is employed for making Catamarans, and is also hollowed out into grain measures, &c.—*Ains. Mat. Med. p.* 206. Myrobalans are the dried fruits of trees very common in many districts of India; viz: several species of *Terminalia.* They are much valued as a tanning material. The myrobalans are about an inch in length, about the size and shape of a Spanish olive, with an ash yellow coloured pericarp, generally strongly marked with longitudinal wrinkles. They have become a very important

item in commerce, but their introduction to general use can only date back about ten years. The imports into England, according to Mr. Poole, now amount to about 1200 tons annually: from Madras, 1853-54, the exports were 4,145 cwt. value 8,447 Rs.—*M. E J. R.*

(8112) TERMINALIA BERRYI. COMBRETACEÆ.

Vellai maroodóo, TAM.	Vallay murdah marum, TAM.
Vellay murdah wood, ENG.	

This, judging from some introduced plants growing in Coimbatore, is a very large tree. The bark is quite smooth, and nearly as green as the leaves. The wood is white, described as of ordinary quality, used on the coast for canoes, and for making the broad wooden platters in use among fishermen and ship lascars.—*Wight.* This tree attains a large size, especially at the foot of the W. Ghauts, where it is used for canoes, &c. (Wight). Wight No. 111, Travancore 225, 320, Hort. Garden 64.—*M. E. J. R.*

(8113) TERMINALIA CATAPPA, Lin. Icon. 172. *Combretaceæ.*

Country almond tree, ENG.	Vadom vettello, TEL.
Nattoo vadom cottay, also Nattoo vadom marum, TAM.	Catappa, MALAY.
Budamie, HIND	Ingudi SANS.
	Badam, BENG.

A beautiful large tree, found in gardens, &c, the kernels are eaten and are palatable, the wood is also useful. (Wight No. 54, Hort. Garden 63.)—*M. E. J. R. T. Catappa* has obovate leaves, tapering to the base, pubescent beneath, and glands on the under sides of the midrib. It is originally a native of the East Indies, but has now become naturalised in the West India Islands. Some botanists have described the West India species as distinct from the Asiatic, but there is no good distinctive character. The drupaceous fruit of this tree is about 3 inches long, and contains a large seed, which is eaten, and also yields an oil, in the same manner as the almond. This tree, on account of its thick foliage, is much planted in the tropics for the purpose of forming avenues near houses. The bark and leaves yield a black pigment. Indian ink is manufactured from the juice of this tree.—*Eng. Cyc.* This is probably a Malayan species, but is cultivated in India, and is a valuable timber tree. Drupe three inches long, egg-shaped, grooved; kernel resembles the almond or filbert in taste and composition; yields an excellent fixed oil, and is good nourishing food. The bark and leaves are very astringent, and yield a black paint.—*O'Shaughnessy, page* 341. In the Kotah gardens this is a very handsome garden tree.—*Genl. Med. Top. p.* 193. *Terminalia Catappa* grows commonly in all parts of the Deccan. It is raised easily from seed, and in a good light soil, well watered, will in two years be ten or more feet in height, and give blossom. It is rather a handsome tree, and, from its large leaf (which turns red previous to its falling off,) has a very striking appearance. The fruit is of the size of a coarse plum, and the kernel, contained within the shell, resembles the English Filbert in flavour. It is produced at table with the desert.—*Riddell.* This tree is procurable in Malayalum. The wood, judging from an outside specimen, has a good deal the appearance of beech, showing much silver grain in some sections, but it is more porous and not so close grained.—*Wight.* It attains a large size in Malabar where the wood is much esteemed, it is called by the English, the Almond tree, from the oval shape of the fruit, but the kernel is cylindrical.—*Wight.* It is reckoned a valuable wood by the natives, who generally employ it in making Pikoties.—*Ains. Mat. Med. p.* 206.

The fruit.

Nat Vadomcottay, TAM.	Vadomvittiloo. TEL.
Badam-i-Hindee, DUK.	Hinghoodie, SANS.

This has got the appellation of country Almond, in India, from its resemblance to the Persian fruit of that name in taste and appearance, though it has, perhaps, more the flavor of an English filbert. It is the produce of a very large and certainly one of the most beautiful trees in the world. The tree is the Adoa marum of the Hortus Malabaricus, the Malayas call it Catappa. The kernels of this large and most beautiful tree are recommended by the Vy theans as a light and nourishing diet for weak people.—*Ains. Mat. Med. p.* 92 and 228.

(8114) TERMINALIA CHEBULA. (CHEBULIC MYROBALAN.) Myrobalana Chebula, Gærtn. ii. t. 97.

Pillamarrda, CAN.	Heleiji kabule, ARAB.
Heerda, also Huldah, DUK.	Helileh Kelan, PERS.
	Pilla murdah wood, ENG.
Pilla murda or Kadoo-koy, TAM.	Karaka Chettoo, TEL.
Alali mara, CAN.	Har Hara, Umbed'her, HIND.
Araloo, CING.	Kayoobin, BURM.
Haritaka, SANS.	

This large timber is plentiful throughout the Pegu Teak Forests, wood, red-colored, strong and adapted for house-building.—*McClelland.* In Tenasserim the fruit of the Terminalia Chebula mixed with an iron clay is in common use to form a black dye, which is said to be very good. All the Burmese native ink is made from this fruit, but although black when used, in the course of a dozen years it sometimes fades so that the writing is scarcely legible. The tree is found throughout the Tenasserim Provinces, but is not very abundant.—*Mason.*

It flowers in May. The moochies use the fruit to form a black dye.—*Riddell.* The tender leaves of *Terminalia chebula* are punctured by an insect, and its eggs deposited therein; hollow galls, Huldee Kay, *Tel.* Kadukay, *Tam.* are subsequently formed, these are powerfully astringent,

and make as good ink as oak galls. They also yield to Chintz painters and the Carpet weavers at Ellore the most durable yellow. Mr. Rohdes states that it forms perfect leather, but is too expensive for ordinary tanning purposes.—*M. E. J. R.* The trivial name *Chebula*, is from *Cabul*, where it is very abundant. It is a large tree, native of the forests of India from Cape Comorin to the mountains of Oude &c. The tender leaves are punctured by an insect and its eggs deposited therein becomes enlarged into hollow galls, they are a powerful astringent and make as good ink as oak galls, they also yield the chintz painters, and Carpet weavers their best and most durable yellow. They are called by the Tamuls "kadukay" and by the Telingas aldicoya.—*Rohdes' M.S.S. Terminalia Chebula* is distinguished by possessing opposite leaves which are pubescent beneath. The fruit of this species is more astringent than the others and is used for the purposes of dyeing. A durable ink is made by mixing the salts of iron with an infusion of the outer rind of the fruit. Both this species and others are subject to the attacks of insects producing gall-nuts. These galls possess the astringent principle in abundance, and are also used for dyeing. They are called Cadacay by the Tamuls.—*Eng. Cyc.* This most gigantic tree, furnishes planks 3 feet broad. It has a dark coloured, heavy and hard wood, but very cross grained and difficult to work. It sustained about 400 lbs.—*Wight.* It is common in the Kotah jungles (*Irvine, p.* 193.): also in the forests of Bengal and common in the forests of Western India.

Trunk rarely straight, short, bark ash-coloured, branches numerous and spreading. Fruit very astringent; in its dry state about the size of an olive. With catechu it is applied with great advantage in apthous ulcerations. The *Zengi Har* of Bengal, Singi, *Tamul.* Kurkadaga *Sans.* (Black Myrobalan), is described by Ainslie as the unripe dried fruit, and as a brisk purge. It is deep black, oblong, pointed and slender. It is called *Ahleeluj-asood* by the Arabs, *Helileh-seeah* by the Persians, who give it as a cathartic, in doses of from 1 to 2 drachms with a little honey.—*O'Shaughnessy, page* 320.

(8115) TERMINALIA CITRINA. CITRON MYROBALAN.

Liba, SANS. | Haria, Harra, HIND.

Common in the Kotah jungles. All these Myrobalans are largely collected, and used by the natives in dyeing and in medicine.—*Gen. Med. Tob. p.* 103. Drupe oblong, lanceolate, about two inches long, two in circumference, obscurely five-grooved, dull orange-yellow, smooth; nut oblong, deeply five-grooved, one-celled. Fruit a gentle purgative. It is often made into a pickle.—*O'Shaughnessy, p.* 340.

(8116) TERMINALIA GLABRA. COMBRETACEÆ,

Karai Maroodoo maram, TAM. | Curry murdah wood, ENG.

Icon. 196, nearly represents this species. Dr. Wight speaks highly of this wood, and states that large beams are readily procurable at Coimbatore for house building purposes. It is very hard, heavy and durable under water. (Wight No 16, Travancore 78, 101, 383, Mysore 30, Paulghaut 21, Cleghorn.)—*M. E. J. R.* Inch bars bear from 430 to 450 lbs.—*Wight.*

(8117) TERMINALIA MOLUCCANA. (Sylhet, Moluccas.) Drupe round, ovate, size of a large nutmeg, used as T. bellerica, for which it is substituted.—*O'Shaughnessy, page* 341.

(8118) TERMINALIA NITIDA.

Yella, DUK.

A large tree with oblong fruit, from which an intoxicating liquor is made.—*Riddell.*

(8119) TERMINALIA RUBRICA.

Vibbituka, SANS.	Tandra maram, TAM.
Bahira, BENG.	Tani, RHEED.
Beleyleh, ARAB.	Toondee, TEL.

A native of the mountainous parts of the Circars, growing to be one of the largest trees, with an erect trunk, and very spreading head. The kernel of the fruit is eaten by natives, but is reckoned intoxicating when eaten in any quantity. Wood white, rather soft, durable and seldom used. From wounds in the bark large quantities of insipid gum issues. The flowers have a strong offensive smell.—*Roxb. Rohdes, M. S. S.*

(8120) TERMINALIA VERNIX. One of the trees which affords the celebrated Chinese black lacquer.—*O'Shaughnessy, p.* 341. *Terminalia vernix*, is a native of China, and the Moluccas, and abounds in a resinous juice, which is collected by the inhabitants, and used in the natural state as a varnish. It is also used for the same purpose in China.—*Eng. Cyc.*

(8121) TERMINALIA VIOLATA.

Panjah, BURM.

Both this and *Terminalia belerica*, "Lai-bwai" *Burm.* are very plentiful throughout the Pegu, Tounghoo, and Tharawaddy Forests; the former less plentiful. Both are large timber and would answer for all purposes of house-building. Wood, white colored, adapted to every purpose of house building.—*McClelland.*

(8122) TERMITINÆ, a section of Neuropterous Insects, in which Latreille includes the genera *Mantispa, Raphidia, Termes*, and *Psocus.* These genera however are usually regarded as constituting three distinct families.

(8123) TERMITIDÆ. This family is distinguished by the following characters:—Wings with few transverse nervures, folding horizontally; tarsi 4-joined; antennæ short and moniliform; body depressed.

(8124) TERMES, has the head large and rounded, and, besides the ordinary compound eyes, it has three ocelli, or simple eyes, situated on

the upper surface; the antennæ are as long as the head and thorax, inserted in front of the eyes, and composed of about 18 joints. The abdomen is terminated by two small jointed appendages.

(8125) TERMITES, OR WHITE ANTS.

Anai, MALAY. | Chelloo, TAM.
Dewuk, HIND. | Cheduloo, TEL.

White ants, as they are often called (though they have little affinity with the true Ants), are chiefly confined to the tropics; some few species however extend into the temperate regions. Like the Bees, Wasps, and Ants, which live in society, the Termites are composed of three kinds of individuals—males, females, and what are termed neuters or workers. Their ravages in the warmer parts of the globe are well known. They unite in societies composed each of an immense number of individuals, living in the ground and in trees, and often attacking the wood-work of houses, in which they form innumerable galleries, all of which lead to a central point. In forming these galleries they avoid piercing the surface of the wood-work, and hence it appears sound when the slightest touch is sometimes sufficient to cause it to fall to pieces. The Termites sometimes erect their domiciles on the ground, in the form of pyramids or cones, sometimes with a roof, and these nests are often very numerous, and resemble the huts of savages. The larvæ nearly resemble the perfect insect, excepting that they possess no wings. The pupæ have rudimentary wings. The neuters differ from the males and females in possessing no wings, in having the body stouter, the head much longer, and provided with long jaws crossing at the extremity. They are said to defend the nests, and, stationing themselves near the outer surface, they are the first to make their appearance when their habitation is disturbed. They will attack the party molesting them, and bite with considerable strength. The negroes and Hottentots in Africa and people of India, consider these insects a great delicacy. They are destroyed with quick-lime, or more readily with arsenic, which is thrown into their habitations.—*Eng. Cyc.*

(8126) TERNSTROMIACEÆ, *Theads*, a natural order of Polypetalous Exogenous Plants. It consists of trees or shrubs with alternate coriaceous leaves, without stipules, mostly undivided, and sometimes with pellucid dots. The flowers are generally white in colour, sometimes pink or red, and are arranged in axiliary or terminal peduncles, articulated at the base. The calyx is composed of 5 or 7 sepals, imbricated in æstivation, the innermost the largest; petals 5, 6, or 9, often combined at the base; stamens indefinite, with monadelphous or polyadelphous filaments, and versatile or adnate anthers; ovary superior; capsule 2-7-celled; seeds few, attached to a central axis, with little or no albumen, and a straight embryo, the cotyledons of which are very large, and often filled with oil. This order includes the *Theaceæ* of Mirbel and the *Camelliæ* of De Candolle. Their closest affinity is with the order *Guttiferæ*, from which they differ in their alternate leaves; in the parts of their flowers being 5 and its multiples; in the calyx being distinct from the corolla; in their twisted æstivation, and in their thin inadherent cotyledons. They have also relations with Hypericaceæ and Marcgraaviaceæ. The plants of this order are principally inhabitants of Asia and America and one species of Africa.—*Eng. Cyc.*

(8127) TERU-KUNDLE, the Tamil name of a Ceylon tree which grows to about two feet in diameter, and twelve feet in height. It is used in country vessels, and produces a fruit which is eaten by the natives.—*Edye, Ceylon.*

(8128) TETRAGONIACEÆ, *Aizoons*, a natural order of Exogenous Plants. It includes the Genera *Tetragonia*, *Aizoon*, *Sesuvium*, and *Miltus*, which are generally placed in the order *Ficoideæ*, or *Mesembryaceæ*. The reason given by Dr. Lindley for this separation is the want of petals in these genera, as he considers that the tendency to produce petals in the *Mesembryaceæ* is of too powerful a nature to admit exception. The relation of these apetalous *Ficoideæ* to *Chenopodiaceæ* is so strong, that Dr. Lindley says "there is no character to distinguish them except their ovary being formed of several carpels."—*Eng. Cyc.*

(8129) TETRAGONIA EXPANSA is a native of New Zealand and Japan, and is used by the natives of those countries as a remedy in those forms of cutaneous disease called scorbutic. The *Aizoon Canariense* and *A. Hispanicum* grow on the sea-coasts of the Canary Isles and Spain, and are amongst the plants which yield soda after burning.—*Eng. Cyc.*

(8130) TETRANTHERA, a genus of plants belonging to the natural order *Lauraceæ*. The flowers are diœcious, some hermaphrodite, involucrated. The calyx 6-parted, the segments nearly equal or wanting. The fertile stamens generally about 9, in the petaloid flower than 12 to 21. The leaves are variable, with pinnate veins.—*Eng Cyc.*

(8131) TETRANTHERA MONOPETALA.

Junglee race am HIND. | Nara mamidee TEL.

(8182) TETRANTHERA ROXBURGHII, NESS. *Syn.* SEBIFERA GLUTINOSA, Loureiro. Tetranthera apetala, Roxb. Corom. Pl t. 147. and Fl. Ind. iii. p. 819. Litsea sebifera, *Pers.*

Mueda ka jhar, HIND.

Mountains of India. The wood is the *mueda lukree* of Hindostanee druggists, and a favourite application to bruises and wounds. It is somewhat fragrant, and slightly balsamic and sweet. —*O'Shaughnessy, p.* 548. *Tetranthera Roxburghii* is a variable plant, a native of the mountains of India and China. The fruit is globose, black and about the size of a pea, yielding a kind

of greasy exudation from which the Chinese manufacture candles of a bad quality, and which serves as a basis for salves. This fixed oil is supposed to constitute the principal part of the fruit of *Persea gratissima*, so much esteemed in the West Indies under the name of Avocado Pear.—*Eng. Cyc.* Wight gives in Icones Tetranthera, glabrata, 1838; ligustrina, 1835; monopetala, 1833; Panamanja, 1836; tomentosa, 1834; Wightiana, 1833.

(8133) TETRANTHERA TOMENTOSA. LAURACEÆ, Icon. 1834.

Mussay payattie, TAM.

This is a considerable sized tree, but not described by Roxburgh, though he is the authority for the name, hence, says Wight, I am unable to learn any thing of its properties from his work.—*Wight.*

(8134) TETRAO-PERDIX NIVICOLA, Dr. Hooker says that when he descended, he breakfasted on this, the Himalayan grouse, a small gregarious bird which inhabits the loftiest stony mountains, and utters a short cry of "Quiok, quiok." In character and appearance it is intermediate between grouse and partridge, and is good eating, though tough.—*Hooker. Him. Jour. Vol.* II. *p.* 113.

(8135) TETRAONIDÆ, a family of Rasorial Birds, to which the common Grouse belongs. Mr. Swainson thus defines the "*Tetraonidæ*, Partridges and Grouse:—Bill and tail very short; hallux elevated;" and he comprises under the family the following genera and sub-genera:—

Oryptonyx, Temm.; *Odontophorus*, Vieill.; *Ortygis*, Ill.; *Tetrao*, with the sub-genera, *Tetrao*, Linn., *Lagopus*, Willughby, *Lyrurus*, Sw., *Pterocles*, Temm., and *Centrocercus*, Sw., *Perdix*, of Briss., with the sub-genera *Perdix*, *Chætopus*, Sw., *Coturnix*, Briss., *Ptilopachus*, Sw., and *Ortix*, Stedh.; *Crypturus*, Ill., with the sub-genera *Crypturus* and *Nothurus*, Wagl.

Mr. G. R. Gray, in his 'List of the Genera of Birds,' arranges the *Tetraonidæ* between the *Phasianidæ* and the *Chionididæ*, with the following sub-families and genera:—

1. *Perdicinæ.*

Genera:—*Rhizothera*, G. R. Gray; *Ptilopachus*, Sw.; *Ithaginis*, Wagl.; *Lerwa*, Hodgs; *Pternistes*, Wagl.; *Francolinus*, Briss.; *Chacura*, Hodgs.; *Perdix*, Antiq.; *Arborophila*, Hodgs.; *Coturnix*, Antiq.; *Rollulus*, Bonn.; *Odontophorus*, Vieill.; *Ortyx*, Steph.; *Lophortyx*, Bonap.; *Callipepla*, Wagl.

2. *Tetraoninæ.*

Genera:—*Tetrao*, Linn.; *Lyrurus*, Sw.; *Bonasa*, Briss. (*Bonasia*, Bonap.); *Centrocercus*, Sw.; *Lagopus*, Briss.

3. *Pteroclinæ.*

Genera:—*Pterocles*, Temm.; *Syrrhaptes*, Ill.

(8136) *Pterocles Setarius* the Pin-Tailed Sand-Grouse, Ganga Cata, is an example of the Grouse of Asia. This bird is very numerous on the arid plains of Persia. Not very numerous in France, on the sterile Landes near the Pyrenees, and along the coast of the Mediterranean: less common in Provence and Dauphine, where they occasionally arrive; more common in Spain, Sicily, Naples, and throughout the Levant. Temminck, who gives these localities, states, in the fourth part of his 'Manual,' second edition, that it is common in Provence, in the uncultivated plains of Crau, and says that it avoids cultured tracts, and only inhabits the sterile Landes of the south; but he adds that it is abundant in the Pyrenees, and that it is to be found all the year round in the markets of Madrid. Mr. Gould states that the species is found in the north of Africa. It feeds on seeds, insects, and the young shoots of plants.—*Eng. Cyc.*

(8137) *Cryptonyx*, is a genus which has been variously placed, and by some amongst *Tetraonidæ*. It has the following characters:—Bill strong, stout, compressed, convex above, curved towards the point; nostrils longitudinal, placed in the middle of the bill, and covered by a naked membrane; orbits and lore naked; hind toe without any nail, not touching the ground. Wings short; third, fourth, and fifth quills longest.

(8138) *Cryptonyx cristatus* (*C. coronatus*, Temm.), is the Rouloul de Malacca of Sonnerat. According to Mr. T. C. Eyton, the Malay native name is Bestum ('Catalogue of a Collection of Birds from Malaya,' &c.,) in 'Zool. Proc.,' 1839.

These beautiful birds haunt the great forests of Malaya, Sumatra, and Java. Wild and shy, they avoid the face of man, and are kept in captivity with great difficulty.—*Eng. Cyc.*

(8139) TETRODON, a genus of Fishes of the order *Plectognathi*. These fishes, instead of having distinct teeth as usual in the class, have the jaws provided with a substance resembling ivory, formed somewhat like the beak of a bird, and fitted for crushing crustaceous animals and *Fuci*, upon which they live. Both the Tetrodons and Diodons (*Diodon*, Linn), a very closely allied genus, have the power of inflating the body with wind, or rather a membrane, which extends along the under side of the abdomen, which causes them to float on the surface of the water, without the power, it is said, of directing their course; the membrane, when inflated, gives to the fish an almost spherical form and is usually defended by spines and prickles. The pectoral fins are rather small; and besides these and the tail fin, they have one dorsal and a ventral fin. The Diodons have but one large tooth above and below, and are usually protected by large st rong spines. The Tetrodons are distinguished by the possession of four large teeth, the jaws being each divided by a central suture. These fishes are confined to the

seas of warm climates: some of them are called Globe-Fishes.—*Eng. Cyc.*

(8140) TEUCRIUM (from Teucer), a genus of plants belonging to the natural order *Lamiaceæ*, or *Labiatæ*.

(8141) TEUCRIUM SCORODONIA, Wood Germander, or Sage, has cordate downy petiolate-crenate leaves; the flowers are of a pale-yellow colour, with violaceous stamens, and are arranged in lateral and terminal 1-sided racemose; the stem is erect, hispid, pubescent, or nearly glabrous. It is a native of Europe in woody hilly situations, where the soil is dry and stony. It is not an uncommon plant in Great Britain. The smell and tasste of this plant resemble very much the hop. In Jersey, where it is called Ambroise, the inhabitants use it as a substitute for hops in their beer; and by some persons the bitter given by the Germander is preferred to that of the hop.

(8142) TEUCRIUM SCORDIUM. It is a native of Europe and the temperate parts of Asia in boggy wet places.

(8143) TEUCRIUM CHAMÆDRYS, Wall, or Common Germander, has ovate incisoserrate leaves, tapering into a footstalk; the flowers are reddish-purple, and arranged in axillary whorls of three flowers; the stem is ascending, and most frequently villous. It is a native of Europe and some parts of Asia, on walls and rocks and dry places. It is only rarely found in Great Britain. —*Eng. Cyc.* This is an ingredient in the celebrated Theriaca andromachi, or *treaq farooq*.—*O'Shaughnessy, p.* 488.

(8144) TEXTILE ARTS. The East has, from the earliest times of which we have any record, been famous for its textile fabrics; and India, notwithstanding the great mechanical inventions of the western world is still able to produce her "webs of woven air," which a Manufacturer of the last century attempted to depreciate, by calling them "the shadow of a commodity," at the same time that his townsmen were doing all they could to imitate the reality, and which they have not yet been able to excel.

Cotton Manufacture.—Though the invention and completion of a loom for weaving would indicate a high degree of ingenuity as well as a considerable advance in some other arts, the Hindoos were acquainted with it at a very early period, for in the hymns of the Rig Veda, composed at least 1200 years B. C., "weavers' threads" are alluded to; and in the Institutes of Manu it is directed,—"Let a weaver who has received ten bales of cotton-thread give them back, increased to eleven by the rice-water and the like used in weaving." That cotton was employed at very early periods is also evident from the Indian name of cotton, *Karpas*, occurring in the Book of Esther, ch. i. v. 6, in the account of the hangings in the court of the Persian palace at Shushan, on the occasion of the great feast given by Ahasuerus, were "white, green, and blue hangings." The word corresponding to *green* is *Karpas* in the Hebrew. It seems to mean cotton-cloth made into curtains, which were striped white and blue. Such may be seen throughout India in the present day, in the form of what are called *purdahs*. Vide "Essay on Antiquity of Hindoo Medicine," *p.* 145. The mode in which these are used, and the employment of the same colours in stripes, is still shown in *sutrunjees*, or cotton carpets. That the Hindoos were in the habit of spinning threads of different materials appears, from another part of the Institutes of the same lawgiver, where it is directed that the sacrificial threads of a Brahmin must be made of cotton, that of a shatriya (second caste,) of *sana* (*Crotalaria juncea*) and that of a Vaisya, of woollen thread. The natives of India prepare fabrics not only of cotton, but also of hemp, and of jute, and other substitutes for flax; also of a variety of silks, and of the wool of the sheep, goat, and camel, as well as mixed fabrics of different kinds. But it is for the delicacy of the muslins, especially of those woven at Dacca, that India has so long been famous. It is pleasing to find that these manufactures still continue pre-eminent for fineness combined with softness. From a careful examination of the cottons grown in different parts of India, as well as of those of other parts of the world, we find that it is not owing to any excellence in the raw material that the superiority in the manufacture is due, for spinners, here, say that the Indian cotton is unfit for their purposes, being not only short but coarse in staple. It is owing, therefore, to the infinite care bestowed by the native spinners and weavers on every part of their work, that the beauty of the fabric is due; aided, as they are, by that matchless delicacy of touch for which the Hindoos have long been famous. But this is no small advantage, for, according to one of their authors, the first, the best, and most perfect of instruments is the human hand." Experiments were made for a series of years, at the expense of the Indian Government, to grow American cotton in the Dacca district, but without success, owing, it was thought by the American planter in charge, to excess of moisture, and to the depredations of insects.—*Royle.* The Hindoo weaver is often described as hanging his loom to a tree, and sitting with his feet in the ground. If he did so, his productions would appear more wonderful than they are, as being still more the result of means unsuited to the end. But a late resident of Dacca has given a minute account of the cotton manufacture of that district, and thence we learn positively, what might as certainly have been inferred, that great care is bestowed on every part of the process. The spinning-wheel is usually consi-

dered to be an improvement upon the distaff and spindle as our machinery is upon the inexpensive spinning-wheel. In facilitating work and diminishing expense, the spinning-wheel was, no doubt, a great improvement, and is still employed throughout India for the ordinary and coarser fabrics. But the spindle still holds its place in the hands of the Hindoo woman, when employed in spinning thread for the fine and delicate muslins to which the names of "Dew of Night," "Running Water," &c., are applied by the natives, and which, no doubt, formed the *Tela ventosa* of the ancients; and those called *Gangitika* in the time of Arrian were probably produced in the same locality. Mr James Taylor, late of the medical service of Bengal, in a report which was sent by the Court of Directors to India, gave much interesting information respecting the cotton manufacture of Dacca: and to the Exhibition of 1851, he sent a series of views of the different parts of the process, together with the instruments used in spinning, as well as some specimens of their fine thread. He shows that the Hindoo woman first cards her cotton with the jaw-bone of the *boalee* fish, which is a species of Silurus; she then separates the seeds by means of a small iron roller worked backwards and forwards upon a flat board. An equally small bow is used for bringing it to the state of a downy fleece, which is made up into small rolls to be held in the hand during the process of spinning. The apparatus required for this consists of a delicate iron spindle, having a small ball of clay attached to it, in order to give it sufficient weight in turning, and imbedded in a little clay there is a piece of hard shell, on which the spindle turns with the least degree of friction. Besides these, a moist air and a temperature of 80° is found best suited to this fine spinning, and it is therefore practised early in the mornings and in the evenings, sometimes over a shallow vessel of water, the evaporation from which imparting the necessary degree of moisture. The spinners of yarn for the Chundeyree muslins in the dry climate of North-West India are described as working in underground work-shops, on account of the greater uniformity in the moisture of the atmosphere. The Indian spinning-wheel is looked upon with contempt by those who look to the polish rather than to the fitness of a tool. Professor Cowper, than whom none is a better judge, observing that the wood-work of some of these spinning-wheels was richly carved, inferred that the strings with which the circumference was formed might have some use, and not have been adopted from poverty or from idleness. In making working models of these instruments, he has found that in no other way could he produce such satisfactory results as by closely imitating the models before him, the strings giving both tension and elasticity to the instrument. The spindles, moreover, being slightly bent or the hand held obliquely, the yarn at every turn of the spindle slips off the end and becomes twisted As the different processes are fully described in the work alluded to, I need not, says Dr. Royle, dwell further on this part of the subject, except to mention that the common dimensions of a piece of Dacca muslin are twenty yards in length by one in breadth. There are more threads in the warp than in the woof, the latter being to the former in a piece of muslin weighing twenty tolas or siccas, in the proportion of 9 to 11; one end of the warp is generally fringed, sometimes both. The value of a piece of plain muslin is estimated by its length and the number of threads in the warp, compared with its weight. The greater the length and number of threads and the less the weight of the piece, the higher is its price. It is seldom, however, that a web is formed entirely of the finest thread which it is possible to spin. The local committee of Dacca having given notice that they would award prizes for the best piece of muslin which could be woven in time for the Exhibition, the prize of 25 rupees was awarded to Hubeeb Oolla, weaver of Golkonda, near Dacca. The piece is ten yards long and one wide, weighs only 3 oz. 2 dwts. and may be passed through a very small ring. Though the cotton manufactures of India have so greatly fallen off, from the cheapness of English manufactured goods, it is gratifying, as well as unexpected, to learn from Mr. Taylor, that, as the finest muslins formed but a small portion of the goods formerly exported to England, the decay of the Dacca trade has had comparatively little influence on this manufacture, as these delicate manufactures still maintain their celebrity in the country, and are still considered worthy of being included among the most acceptable gifts that can be offered to her native princes; and he believes that the muslin made at present is superior to the manufacture of 1790, and fully equal to that of the reign of Aurungzebe. He also informs us that a College for the education of the natives, stands on the site of the former English factory. Fine muslins were sent to the Exhibition of 1851, not only from Dacca, but also from Kishengurh in Bengal; likewise from as far south as Collar, in the Rajah of Travancore's dominions, as well as from Chundeyree in the Gwalior territories. Specimens of almost every variety of the cotton manufacture such as the coarse garrhas and guzzees for packing, clothing, and for covering corpses, with dosootees, &c. for tents, canvas for sails, towels, and table-cloths, and every variety of calico, were sent from the islands of the Indian Ocean, from Nepal and Assam, as well as from all along the valley of the Ganges, from Bengal up to the Jullundur Doab, in the Sikh territories; also
